## TABLE OF CONTENTS

SECTION 1: INTRODUCTION ..... 1
SECTION 2: SUMMARY OF METHODS ..... 7
2.1 Broodstock Collection and Sampling ..... 7
2.2 Within Hatchery Monitoring ..... 9
2.3 Juvenile Sampling ..... 10
2.4 Spawning/Carcass Surveys ..... 12
SECTION 3: WENATCHEE STEELHEAD ..... 19
3.1 Broodstock Sampling ..... 20
3.2 Hatchery Rearing ..... 25
3.3 Disease Monitoring ..... 37
3.4 Natural Juvenile Productivity ..... 37
3.5 Spawning Surveys ..... 44
3.6 Life History Monitoring ..... 48
3.7 ESA/HCP Compliance ..... 66
SECTION 4: WENATCHEE SOCKEYE SALMON ..... 69
4.1 Broodstock Sampling ..... 69
4.2 Hatchery Rearing ..... 75
4.3 Disease Monitoring ..... 80
4.4 Natural Juvenile Productivity ..... 80
4.5 Spawning Escapement ..... 85
4.6 Carcass Surveys ..... 86
4.7 Life History Monitoring ..... 89
4.8 ESA/HCP Compliance ..... 105
SECTION 5: WENATCHEE (CHIWAWA) SPRING CHINOOK ..... 107
5.1 Broodstock Sampling ..... 108
5.2 Hatchery Rearing ..... 115
5.3 Disease Monitoring ..... 122
5.4 Natural Juvenile Productivity ..... 123
5.5 Spawning Surveys ..... 142
5.6 Carcass Surveys ..... 149
5.7 Life History Monitoring ..... 155
5.8 ESA/HCP Compliance ..... 173
SECTION 6: NASON CREEK SPRING CHINOOK ..... 177
6.1 Broodstock Sampling ..... 177
6.2 Hatchery Rearing ..... 180
6.3 Disease Monitoring ..... 183
6.4 Natural Juvenile Productivity ..... 183
6.5 Spawning Surveys ..... 192
6.6 Carcass Surveys ..... 194
6.7 Life History Monitoring ..... 196
6.8 ESA/HCP Compliance ..... 204
SECTION 7: WHITE RIVER SPRING CHINOOK ..... 207
7.1 Captive Brood Collection ..... 207
7.2 Hatchery Spawning and Release ..... 209
7.3 Disease Monitoring ..... 214
7.4 Natural Juvenile Productivity ..... 215
7.5 Spawning Surveys ..... 223
7.6 Carcass Surveys ..... 225
7.7 Life History Monitoring ..... 227
7.8 ESA/HCP Compliance ..... 240
SECTION 8: WENATCHEE SUMMER CHINOOK ..... 243
8.1 Broodstock Sampling ..... 243
8.2 Hatchery Rearing ..... 250
8.3 Disease Monitoring ..... 257
8.4 Natural Juvenile Productivity ..... 258
8.5 Spawning Surveys ..... 261
8.6 Carcass Surveys ..... 265
8.7 Life History Monitoring ..... 270
8.8 ESA/HCP Compliance ..... 284
SECTION 9: METHOW SUMMER CHINOOK ..... 287
9.1 Broodstock Sampling ..... 287
9.2 Hatchery Rearing ..... 294
9.3 Disease Monitoring ..... 300
9.4 Natural Juvenile Productivity ..... 301
9.5 Spawning Surveys ..... 304
9.6 Carcass Surveys ..... 308
9.7 Life History Monitoring ..... 313
9.8 ESA/HCP Compliance ..... 326
SECTION 10: OKANOGAN/SIMILKAMEEN SUMMER CHINOOK ..... 329
10.1 Broodstock Sampling ..... 329
10.2 Hatchery Rearing ..... 330
10.3 Disease Monitoring ..... 336
10.4 Spawning Surveys ..... 336
10.5 Carcass Surveys ..... 338
10.6 Life History Monitoring ..... 341
10.7 ESA/HCP Compliance ..... 353

## LIST OF APPENDICES

| Appendix A: | Abundance and Total Numbers of Chinook Salmon and Trout in the Chiwawa River Basin, Washington, 2016. |
| :---: | :---: |
| Appendix B: | Fish Trapping at the Chiwawa and Wenatchee Smolt Traps during 2016. |
| $\underline{\text { Appendix } C \text { : }}$ | Summary of CSS PIT-Tagging Activities in the Wenatchee River Basin, 2016. |
| Appendix D: | Wenatchee Steelhead Spawning Escapement Estimates, 2016. |
| Appendix E: | Examining the Genetic Structure of Wenatchee River Basin Steelhead and Evaluating the Effects of the Supplementation Program. |
| Appendix F: | NPDES Hatchery Effluent Monitoring, 2016. |
| Appendix G: | Steelhead Stock Assessment at Priest Rapids Dam, 2016. |
| Appendix H: | Wenatchee Sockeye Salmon Spawning Escapement, 2016. |
| Appendix I: | Genetic Diversity of Wenatchee Sockeye Salmon. |
| Appendix J: | Wenatchee Spring Chinook Redd Estimates, 2016. |
| Appendix K: | Genetic Diversity of Natural Chiwawa River Spring Chinook Salmon. |
| Appendix L: | Fish Trapping at the Nason Creek Smolt Trap during 2016. |
| Appendix M: | Fish Trapping at the White River Smolt Trap during 2016. |
| Appendix N: | Genetic Diversity of Upper Columbia Summer Chinook Salmon. |
| Appendix O: | Summer Chinook Spawning Ground Surveys in the Methow and Chelan Rivers, 2016. |

## PREFACE

This annual report is the result of coordinated field efforts conducted by Washington Department of Fish and Wildlife (WDFW), the Confederated Tribes and Bands of the Yakama Nation (Yakama Nation), Chelan County Public Utility District (Chelan PUD), the Confederated Tribes of the Colville Reservation (Colville Tribes), the U.S. Fish and Wildlife Service (USFWS), and BioAnalysts, Inc. An extensive amount of work was conducted in 2006 through 2016 to collect the data needed to monitor the effects of the Chelan and Grant County PUD Hatchery Programs. This work was directed and coordinated by the Habitat Conservation Plans (HCP) Hatchery Committees, consisting of the following members: Bill Gale and Matt Cooper, USFWS; Justin Yeager and Craig Busach, National Marine Fisheries Service (NMFS); Catherine Willard and Alene Underwood, Chelan PUD; Tom Scribner and Keely Murdoch, the Yakama Nation; Mike Tonseth, WDFW; Kirk Truscott, Colville Tribes; and Tracy Hillman, BioAnalysts (Chair). This report also includes monitoring efforts funded by Grant County Public Utility District (Grant PUD). Grant PUD helps fund the spring and summer Chinook monitoring programs. Work funded by Grant PUD was directed and coordinated by the Priest Rapids Coordinating Committee (PRCC) Hatchery Sub-Committee, which consists of the same agency and tribal representatives listed for the HCP Hatchery Committee and replaces Chelan PUD representatives with Grant PUD representatives, Todd Pearsons, Peter Graf, and Deanne Pavlik-Kunkel.

The approach to monitoring the hatchery programs was guided by the updated monitoring and evaluation plan for PUD hatchery programs (Hillman et al. 2013). Technical aspects of the updated monitoring and evaluation program were developed by the Hatchery Evaluation Technical Team (HETT), which consisted of the following scientists: Matt Cooper, USFWS; Tracy Hillman, BioAnalysts; Tom Kahler, Douglas PUD; Greg Mackey, Douglas PUD; Andrew Murdoch, WDFW; Keely Murdoch, Yakama Nation; Todd Pearsons, Grant PUD; Mike Tonseth, WDFW; and Catherine Willard, Chelan PUD. The updated plan also directs the analyses of hypotheses developed by the HETT. Most of the analyses outlined in the updated plan will be conducted in the comprehensive reports.

Most of the work reported in this document was funded by Chelan and Grant PUDs. Bonneville Power Administration purchased some of the Passive Integrated Transponder (PIT) tags that were used to mark juvenile Chinook and steelhead captured in tributaries and also helped fund a portion of the screw trap efforts in Nason Creek. We thank Charlie Paulsen for analyzing PIT-tag data for each program. This is the $11^{\text {th }}$ annual report written under the direction of the HCP.
"I often say that when you can measure something and express it in numbers, you know something about it. When you cannot measure it, when you cannot express it in numbers, your knowledge is of a meager and unsatisfactory kind. It may be the beginning of knowledge, but you have scarcely in your thoughts advanced to the stage of science, whatever it may be."

Lord Kelvin

## SECTION 1: INTRODUCTION

Chelan and Grant PUDs implement hatchery programs as part of their respective agreements related to the operation of Rocky Reach, Rock Island, Wanapum, and Priest Rapids Hydroelectric Projects. The fish resource management agencies developed the following general goal statements for the hatchery programs, which were adopted by the HCP Hatchery Committees and PRCC Hatchery Sub-Committee (hereafter, Hatchery Committees):

1. Support the recovery of ESA-listed species by increasing the abundance of the natural adult population, while ensuring appropriate spatial distribution, genetic stock integrity, and adult spawner productivity.

Includes the Wenatchee spring Chinook, Wenatchee summer steelhead, and Methow spring Chinook programs.
2. Increase the abundance of the natural adult population of unlisted plan species, while ensuring appropriate spatial distribution, genetic stock integrity, and adult spawner productivity. In addition, provide harvest opportunities in years when spawning escapement is sufficient to support harvest.

Includes the Wenatchee sockeye, Wenatchee summer/fall Chinook, Methow summer/fall Chinook, Okanogan summer/fall Chinook, and Okanogan sockeye programs.
3. Provide salmon for harvest and increase harvest opportunities, while segregating returning adults from natural tributary spawning populations.

Includes the Chelan Falls summer Chinook program.
Following the development of the Hatchery and Genetic Management Plans (HGMPs), artificial propagation programs are now characterized into three categories. The first type, integrated conservation programs, are intended to support or restore natural populations. These programs focus on increasing the natural production of targeted fish populations. A fundamental assumption of this strategy is that adults spawned in the hatchery will produce more adult offspring than if they were left to spawn in the river and ultimately provide a demographic boost to the natural population. The second type, safety-net programs, are extensions of conservation programs, but are intended to function as reserve capacity for conservation programs in years of low returns. The safety-net provides a demographic and genetic reserve for the natural population. That is, in years of abundant returns, they function like segregated programs, and in years of low returns, they can be managed as conservation programs. Lastly, harvest augmentation programs are intended to increase harvest opportunities while limiting interactions with wild-origin counterparts.

Monitoring is needed to determine if the hatchery programs are meeting the intended management objectives of conservation, safety-net, or harvest augmentation programs. Objectives for hatchery programs are generally grouped into three categories of performance indicators:

1. In-Hatchery Indicators: Are the programs meeting the hatchery production objectives?
2. In-Nature Indicators: How do hatchery fish from the programs perform after release?
a. Conservation Programs:

- How do the programs affect target population abundance and productivity?
- How do the programs affect target population long-term fitness?
b. Safety-Net Programs:
- How do the programs affect target population long-term fitness?
c. Harvest Augmentation Programs:
- Do the programs provide harvest opportunities?

3. Risk Assessment Indicators: Do the programs pose risks to other populations?

The specific objectives identified in the updated monitoring and evaluation plan are as follows:

1. Determine if conservation programs have increased the number of naturally spawning and naturally produced adults of the target population and if the program has reduced the natural replacement rate (NRR) of the supplemented population.
2. Determine if the proportion of hatchery fish on the spawning grounds affects the freshwater productivity of supplemented stocks.
3. Determine if the hatchery adult-to-adult survival (i.e., hatchery replacement rate, HRR) is greater than the natural adult-to-adult survival (i.e., natural replacement rate, $N R R$ ) and the target hatchery survival rate.
4. Determine if the proportion of hatchery-origin spawners (pHOS or PNI) is meeting management target.
5. Determine if the run timing, spawn timing, and spawning distribution of both the hatchery component is similar to the natural component of the target population or is meeting program-specific objectives.
6. Determine if stray rate of hatchery fish is below the acceptable levels to maintain genetic variation among stocks.
7. Determine if genetic diversity, population structure, and effective population size have changed in natural spawning populations as a result of the hatchery program.
8. Determine if hatchery programs have caused changes in phenotypic characteristics of natural populations.
9. Determine if hatchery fish were released at the programmed size and number.
10. Determine if appropriate harvest rates have been applied to conservation, safety-net, and segregated harvest programs to meet the HCP/SSSA goal of providing harvest opportunities while also contributing to population management and minimizing risk to natural populations

Two additional regional objectives that were not explicit in the goals specified above but were included in the updated monitoring and evaluation plan because they relate to goals and concerns of all artificial production programs include:
11. Determine if the incidence of disease has increased in the natural and hatchery populations.
12. Determine if the release of hatchery fish affects non-target taxa of concern (NTTOC) within acceptable limits.
Objective 12 was completed using an extensive risk assessment that concluded risks from the PUD hatchery programs were within containment objectives approved by the Hatchery Committees (Mackey et al. 2014; Pearsons et al. 2012).

Objectives in the updated plan have been organized in a hierarchy where productivity indicators are the primary metrics used to assess if conservation and safety-net program goals have been met; harvest rates and effects on non-targeted populations are used for harvest programs. In cases where productivity indicators are not available, or results are equivocal, monitoring indicators may be used to help evaluate the performance of the program. Evaluations of monitoring indicators may not provide sufficiently powerful conclusions on which to base management actions; although they may provide insight as to why a productivity indicator did or did not meet the program goal. Therefore, the relationship between hatchery programs and indicators can be viewed in a chain-of-causation: management actions within the hatchery programs affect the status of monitoring indicators, which in turn influence productivity indicators (Figure 1.1).

Figure 1.1. Relationship of indicators to the assessment of propagation programs. Management actions affect monitoring indicators, which influence productivity indicators. Monitoring indicators may be used to hypothesize the magnitude of influence on productivity.

Attending each objective is one or more testable hypotheses (see Hillman et al. 2013). Each hypothesis will be tested statistically following the routines identified in the updated monitoring and evaluation plan. Most of these analytical routines will be conducted at the end of five-year monitoring blocks, as outlined in the updated plan.
Both monitoring and productivity indicators will be used to evaluate the success of the hatchery programs. If the statistical power of tests that involve productivity indicators is insufficient to inform sound management decisions, some of the monitoring indicators may be used to guide management. Figure 1.2 shows the categories of indicators associated with each component of monitoring.

Figure 1.2. Overview of monitoring and evaluation plan categories and components (not including regional objectives).
Throughout each five-year monitoring period, annual reports will be generated that describe the monitoring and evaluation data collected during a specific year. This is the $11^{\text {th }}$ annual report developed under the direction of the Hatchery Committees. The purpose of this report is to describe monitoring activities conducted in 2016. Activities included broodstock collection, collection of life-history information, within hatchery spawning and rearing activities, juvenile monitoring within streams, and redd and carcass surveys. Data from reference areas are not included in this annual report (reference data are in the five-year reports). To the extent currently possible, we have included information collected before 2016.

This report is divided into several sections, each representing a different species, stock, or spawning aggregate (i.e., steelhead, sockeye salmon, spring Chinook salmon, and summer Chinook salmon). For all species, we provide annual broodstock information; hatchery rearing history, release data, and survival estimates; disease information; juvenile migration and productivity estimates; redd counts, distribution, and spawn timing; spawning escapements; and life-history characteristics. For salmon species, we also provide information on carcasses. Brood year 2011 was the final sockeye salmon hatchery release, and beginning in 2013, only natural adult and juvenile sockeye productivity monitoring results are reported. Beginning in 2013, we added a separate section on Nason Creek spring Chinook salmon and in 2014 we added a separate section on White River spring Chinook salmon. The Colville Tribes began conducting monitoring of

Okanogan summer Chinook in 2013; however, we retained the Okanogan summer Chinook section in this report because the PUDs have summer Chinook mitigation obligations in the Okanogan River basin. The Okanogan summer Chinook section includes monitoring information up to the return of brood year 2013 Chinook. Monitoring results for brood years 2013 to present can be found in annual reports prepared by the Colville Tribes to Bonneville Power Administration (BPA). Monitoring results of Grant PUD's fall Chinook salmon mitigation produced at Priest Rapids Hatchery can be found in annual reports written by WDFW and Grant PUD.

Finally, we end each section by addressing compliance issues with ESA/HCP mandates. For each Hatchery Program, WDFW and the PUDs are authorized annual take of ESA-listed spring Chinook and steelhead through Section 10 of the Endangered Species Act (ESA), including:

1. ESA Section 10(a)(1)(A) Permit No. 1395, which authorizes the annual take of adult and juvenile endangered upper Columbia River (UCR) spring Chinook and endangered UCR steelhead associated with implementing artificial propagation programs for the enhancement of UCR steelhead. The authorization includes takes associated with adult broodstock collection, hatchery operations, juvenile fish releases, monitoring and evaluation activities, and management of adult returns related to UCR steelhead artificial propagation programs in the UCR region (NMFS 2003a).
2. ESA Section $10(\mathrm{a})(1)(\mathrm{A})$ Amended Permit No. 18121, which authorizes the annual take of adult and juvenile endangered UCR spring Chinook and endangered UCR steelhead associated with implementing artificial propagation programs in the Chiwawa River for the enhancement of UCR spring Chinook. The authorization includes takes associated with adult broodstock collection, hatchery operations, juvenile fish releases, and monitoring and evaluation activities supporting UCR spring Chinook artificial propagation programs in the UCR region (NMFS 2003, amended in 2015).
3. ESA Section 10(a)(1)(A) Permit No. 18118, which authorizes the annual take of adult and juvenile endangered UCR spring Chinook and endangered UCR steelhead associated with implementing artificial propagation programs in Nason Creek for the enhancement of UCR spring Chinook. The authorization includes takes associated with adult broodstock collection, hatchery operations, juvenile fish releases, and monitoring and evaluation activities supporting UCR spring Chinook artificial propagation programs in the UCR region (NMFS 2003, amended in 2015).
4. ESA Section 10(a)(1)(A) Permit No. 18119, which authorizes the annual take of adult and juvenile endangered UCR spring Chinook and endangered UCR steelhead associated with implementing artificial propagation programs in the White River for the enhancement of UCR spring Chinook. The authorization includes takes associated with adult broodstock collection, hatchery operations, juvenile fish releases, and monitoring and evaluation activities supporting UCR spring Chinook artificial propagation programs in the UCR region (NMFS 2003, amended in 2015).
5. ESA Section 10(a)(1)(A) Permit No. 1347, which authorizes the annual incidental take of adult and juvenile endangered UCR spring Chinook and endangered UCR steelhead through actions associated with implementing artificial propagation programs for the enhancement of non-listed anadromous fish populations in the UCR. The authorization includes incidental takes associated with adult broodstock collection, hatchery operations, juvenile fish releases, and monitoring and evaluation activities associated with non-listed
summer Chinook, fall Chinook, and sockeye salmon artificial propagation programs in the UCR region (NMFS 2003b).

## SECTION 2: SUMMARY OF METHODS

Sampling in 2016 followed the methods and protocols described in Hillman et al. (2013). In this section, we only briefly review the methods and protocols. More detailed information can be found in the updated monitoring and evaluation plan (Hillman et al. 2013).

### 2.1 Broodstock Collection and Sampling

Methods for collecting broodstock are described in the Annual Broodstock Collection Protocols (WDFW 2016). Generally, broodstock were collected over the migration period (to the extent allowed in ESA-permit provisions) in proportion to their temporal occurrence at collection sites, with in-season adjustments dictated by 2016 run timing and trapping success relative to achieving weekly and annual collection objectives. Pre-season weekly collection objectives are shown in Table 2.1 and assumptions associated with broodstock trapping are provided in Table 2.2.
Table 2.1. Weekly collection objectives for steelhead and Chinook in 2016.

| Collection week beginning day | Chiwawa/Nason Spring Chinook ${ }^{\text {a }}$ |  | Hatchery Chelan Falls Summer Chinook | Wild <br> Wenatchee Summer Chinook | Wild Methow Summer Chinook | Wenatchee Steelhead |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Hatchery | Wild |  |  |  | Hatchery | Wild |
| 30 May | 6 | 4 |  |  |  |  |  |

| 19 Sep |  |  |  |  |  | 8 | 8 |
| 26 Sep |  |  |  |  |  | 8 | 6 |
| 3 Oct |  |  |  |  |  | 8 | 4 |
| 10 Oct |  |  |  |  |  | 2 | 2 |
| 17 Oct |  |  |  |  |  | 1 | 2 |
| 24 Oct |  |  |  |  |  | 1 | 2 |
| Total | 108 | 150 | 350 | 270 | 106 | 70 | 68 |

${ }^{a}$ Chiwawa NOR spring Chinook ( $\mathrm{n}=$ up to 80 ) were collected from the Chiwawa Weir with no specific weekly objectives generated, which is consistent with the Broodstock Collection Protocols. Previously PIT-tagged Chiwawa NOR spring Chinook were also targeted at Tumwater Dam. All Nason Creek spring Chinook were collected at Tumwater Dam from the week of 30 May
through the week of 11 July proportionate to run timing. For 2016, HOR Chiwawa spring Chinook were collected for the Nason spring Chinook safety net program.

Table 2.2. Biological and trapping assumptions associated with collecting broodstock for the Chelan and Grant PUD Hatchery Programs, 2016. ${ }^{1}$

| Assumptions | Wenatchee Steelhead | Chiwawa Spring Chinook | Nason Spring Chinook |  | Wenatchee Summer Chinook | Chelan Falls Summer Chinook | Methow Summer Chinook |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

Several biological parameters were measured during broodstock collection at adult collection sites. Those parameters included the date and start and stop time of trapping; number of each species

[^0] origin by natural-origin crosses.
collected for broodstock; origin, size, and sex of trapped fish; age from scale analysis; and prespawn mortality. For each species, trap efficiency, extraction rate, and trap operation effectiveness were estimated following procedures in Hillman et al. (2013). In addition, a representative sample of most species trapped but not taken for broodstock were sampled for origin, sex, age, and size (stock assessment).

### 2.2 Within Hatchery Monitoring

Methods for monitoring hatchery activities are described in Hillman et al. (2013). Biological information collected from all spawned adult fish included age at maturity, length at maturity, spawn time, and fecundity of females. In addition, all fish were checked for tags and females were sampled for pathogens.
Throughout the rearing period in the hatchery, fish were sampled for growth, health, and survival. Each month, lengths and weights were collected from a sample of fish and rearing density indices were calculated. In addition, fish were examined monthly for health problems following standard fish health monitoring practices for hatcheries. Various life-stage survivals were estimated for each hatchery stock. These estimates were then compared to the "standard" survival rates identified in Table 2.3 to provide insight as to how well the hatchery operations were performing. Failure to achieve a survival standard could indicate a problem with some part of the hatchery program. However, failure to meet a standard may not be indicative of the overall success of the program to meet the goals identified in Section 1.
Table 2.3. Standard life-stage survival rates for fish reared within the Chelan PUD hatchery programs (from Hillman et al. 2013).

| Life stage | Standard survival rate (\%) |
| :---: | :---: |
| Collection-to-spawning (females) | 90 |
| Collection-to-spawning (males) | 85 |
| Unfertilized egg-to-eyed | 92 |
| Unfertilized egg-to-ponding | 98 |
| 30 d after ponding | 97 |
| 100 d after ponding | 93 |
| Ponding-to-release | 90 |
| Transport-to-release | 95 |
| Unfertilized egg-to-release | 81 |

Nearly all hatchery fish from each stock were marked (adipose fin clip) or tagged (coded-wire tag) in 2016. Different combinations of marks and tags were used depending on the stock. In addition, Chelan PUD personnel PIT tagged 10,207 juvenile WxW Chiwawa spring Chinook and 10,104 juvenile Nason Creek spring Chinook (5,052 WxW and 5,050 HxH); 5,050 Wenatchee WxW steelhead (Circular Ponds), 12,626 Wenatchee WxW and HxH steelhead (Raceway), and 2,525 Wenatchee steelhead (Blackbird Pond); and 10,103 Chelan River summer Chinook, 5,064 Methow (Carlton) summer Chinook, and 20,994 Wenatchee summer Chinook (10,565 Raceway and 10,429 Circular Ponds). PIT tags will be used to estimate migration timing and survival rates (e.g., smolt-to-adult) outside the hatchery.

Lastly, the size and number of fish released were assessed and compared to programmed production levels. The goal of the program is that numbers released and their sizes should fall within $10 \%$ of the programmed targets identified in Table 2.4. However, because of constraints due to run size and proportions of wild and hatchery adults, production levels may not be met every year.
Table 2.4. Targets for fish released from the PUD hatchery programs; CV $=$ coefficient of variation.

| Hatchery stock | Release targets | Size targets |  |  |
| :--- | :---: | :---: | :---: | :---: |
|  |  | Fork length <br> (CV) | Weight (g) | Fish/pound |
| Wenatchee Summer Chinook |  | $163(9.0)$ | 45.4 | $18^{\mathrm{a}}$ |
| Methow Summer Chinook | 200,000 | $163(9.0)$ | 45.4 | $13-17$ |
| Chelan Falls Summer Chinook (yearlings) | 576,000 | $161(9.0)$ | 45.4 | $13^{\mathrm{b}}$ |
| Chiwawa Spring Chinook | 144,026 | $155(9.0)$ | 37.8 | 18 |
| Nason Spring Chinook | 223,670 | $155(9.0)$ | 37.8 | 18 |
| Wenatchee Steelhead | 247,300 | $191(9.0)$ | 75.6 | 6 |

${ }^{\mathrm{a}}$ An experimental release size of 30-45 grams (10-15 FPP) was in place for brood years 2012-2014.
${ }^{\mathrm{b}}$ An experimental release size of 20-45 grams (10-22 FPP) was in place for brood years 2012-2014.

### 2.3 Juvenile Sampling

Juvenile sampling within streams included operation of rotary screw traps, snorkel observations, and PIT tagging. Methods for sampling juvenile fish are described in Hillman et al. (2013).

A smolt trap was located on the Wenatchee River near the town of Cashmere at RM 8.3 (Lower Wenatchee Trap), in Nason Creek about 0.6 miles upstream from the mouth, in the White River about 5.8 miles upstream from the mouth, and in the Chiwawa River about 0.4 miles upstream from the mouth (Chiwawa Trap). All traps operated throughout the smolt migration period. The Chiwawa Trap operated between 2 March and 21 November 2016. The Nason Creek Trap operated from 1 March to 30 November in 2016. The White River trap operated from 1 March through 30 November 2016. The Lower Wenatchee Trap operated between 29 January and 26 June 2016. Throughout the trapping period, the traps were briefly inoperable during periods when flows were too high or low, during high water temperatures, during large hatchery releases, and because of heavy debris loads, ice, and mechanical malfunctions.

The following data were collected at each trap site: water temperature, discharge, number and identification of all species captured, degree of smoltification for anadromous fish, presence of marks and tags, size (fork lengths and weights), and scales from smolts. Trap efficiencies at each trap site were estimated by using mark-recapture trials conducted over a wide range of discharges. Linear regression models relating discharge and trap efficiencies were developed to estimate daily trap efficiencies during periods when no mark-recapture trials were conducted. The total number of fish migrating past the trap each day was estimated as the quotient of the daily number of fish captured and the estimated daily trap efficiency. Summing the daily totals resulted in the total emigration estimate.

Snorkel observations were used to estimate the number of juvenile spring Chinook salmon, juvenile rainbow/steelhead, and bull trout within the Chiwawa River basin. The focus of the study was on juvenile spring Chinook salmon. Sampling followed a stratified random design with
proportional allocation of sites among strata. Strata were identified based on unique combinations of geology, land type, valley bottom type, stream state condition, and habitat types. A total of 187 randomly selected sites were surveyed during August (Table 2.5). Counts of fish within each sampling site were adjusted based on detection efficiencies, which were related to water temperature. That is, non-linear models that described relationships between water temperatures and detection efficiencies (Hillman et al. 1992) were used to estimate total numbers of fish within sampling sites. These numbers were then converted to densities by dividing total fish numbers by the wetted surface area and water volume of sample sites. Total numbers within a stratum were estimated as the product of fish densities times the total wetted surface or water volume for the stratum. The sum of fish numbers across strata resulted in the total number of fish within the basin. The calculation of total numbers, densities, and degrees of certainty are explained fully in Hillman and Miller (2004).
Table 2.5. Location of strata and numbers of randomly sampled snorkel sites within each stratum that were sampled in the Chiwawa River Basin in 2016.

| Reach/stratum | River miles (RM) | Number of randomly selected sites |

| Reach/stratum | River miles (RM) | Number of randomly selected sites |
| :---: | :---: | :---: |
| 1 | $0.0-0.1$ | 2 |

Working in collaboration with the Comparative Survival Study (CSS) funded by BPA, crews PIT tagged juvenile wild Chinook, wild steelhead, wild sockeye, and in some instances wild coho salmon collected at the smolt traps and collected within the Chiwawa River and Nason Creek using electrofishing techniques. The proposed number of wild spring Chinook and steelhead to be tagged at each location is provided in Table 2.6. The goal of this tagging program is to estimate freshwater juvenile productivity, better understand life-history characteristics, overwinter movement, and survival of salmonids, and to calculate SARs for spring Chinook salmon in the Wenatchee River basin. The PIT tagging effort funded by the PUDs in the Chiwawa River and Nason Creek is specifically directed at addressing uncertainties of estimating abundance using screw traps (e.g., fish passage during times when trapping is not possible).

Table 2.6. Number of wild spring Chinook, steelhead ( $\geq 65 \mathrm{~mm}$ ), and sockeye proposed for PIT tagging at different locations within the Wenatchee River basin, 2016. NT = no sample size target.

| Sampling location | Target sample size |  |  |
| :--- | :---: | :---: | :---: |
|  | Wild spring Chinook | Wild steelhead | Wild Sockeye |
| Chiwawa Trap | $2,500-8,000$ | $500-2,000$ | NT |
| Nason Creek Trap | $2,500-8,000$ | $500-2,000$ | NT |
| White River Trap | $200-500$ | NT | NT |
| Lower Wenatchee Trap | $1,000-2,500$ | $50-250$ | $3,000-5,000$ |
| Chiwawa Remote Sampling | 3,000 | NT | NT |
| Nason Remote Sampling | 3,000 | NT | NT |

Survival rates for various juvenile life-stages were calculated based on estimates of seeding levels (total egg deposition), parr abundance, numbers of emigrants, and smolt abundance. Total egg deposition was estimated as the product of the number of redds counted in the basin times the mean fecundity of female spawners. Fecundity was estimated from females collected for broodstock using an electronic egg counter. Numbers of emigrants and smolts were estimated at trapping sites and numbers of parr were estimated using snorkel observations only in the Chiwawa River basin. Survival estimates could not be calculated for some stocks (e.g., summer Chinook) because specific life-stage abundance estimates were lacking.

### 2.4 Spawning/Carcass Surveys

Methods for conducting carcass and spawning ground surveys are detailed in Hillman et al. (2013). Information collected during spawning surveys included spawn time, redd distribution, and redd abundance. Data collected during carcass surveys included sex, size (fork length and postorbital-to-hypural length), scales for aging ${ }^{2}$, degree of egg voidance, DNA samples, and identification of marks or tags. The sampling goal for carcasses was $20 \%$ of the spawning population.

[^1]Steelhead surveys were conducted throughout the mainstem Wenatchee River and downstream from PIT-tag interrogation systems on the Chiwawa River, Nason Creek, and Peshastin Creek. These surveys were conducted during March through June in reaches and index areas described in Table 2.7. Total redd counts in these reaches were estimated by expanding counts within nonindex areas by expansion factors developed within index areas.
Table 2.7. Description of reaches and index areas surveyed for steelhead redds in the Wenatchee River basin.

| Stream | Code | Reach* | Index/reference area |

* Reaches $2,6,8,9$, and 10 (major spawning areas) are surveyed weekly, while Reaches $1,3,5$, and 7 (minor survey areas) are surveyed during peak spawning.

Beginning in 2014, adult steelhead escapement estimates in the majority of tributaries in the Wenatchee River basin were generated using mark-recapture techniques based on steelhead PIT tagged at Priest Rapids Dam. Mark-recapture estimates in the tributaries were then added to the estimates based on redd surveys to generate a total spawning escapement to the Wenatchee River basin.

Spring Chinook redd and carcass surveys were conducted during August through September in the Chiwawa River (including Rock and Chikamin creeks), Nason Creek, Icicle Creek, Peshastin Creek (including Ingalls Creek), upper Wenatchee River, Little Wenatchee River, and the White River (including the Napeequa River and Panther Creek). Survey reaches for spring Chinook are described in Table 2.8.

Table 2.8. Description of reaches surveyed for spring Chinook redds and carcasses in the Wenatchee River basin.

| Stream | Code | Reach | River mile (RM) |
| :---: | :---: | :---: | :---: |
| Chiwawa River | C 1 | Mouth to Grouse Creek | $0.0-11.7$ |

| Ingalls Creek | D1 | Mouth to Trailhead | 0.0-1.0 |

The sockeye salmon hatchery program ended after the 2011 brood year. As a result, monitoring activities that focused on evaluating the effects of the supplementation program on the natural population switched to monitoring the abundance and productivity of the natural population (McElhaney et al. 2000). Thus, estimation of spawn time and carcass surveys were discontinued in 2014. Nevertheless, this report retains the results of carcass sampling during the period 19932013. Survey reaches in which carcasses and live fish (for area-under-the-curve estimates) were conducted are identified in Table 2.9.

From 2009-2013, mark-recapture methods were used to estimate sockeye spawning escapement within the White River, while area-under-the-curve (AUC) methods were used to estimate
spawning escapement within the Little Wenatchee River. Beginning in 2014, mark-recapture methods were used to estimate the spawning escapement of sockeye in both the White River and Little Wenatchee watersheds.

Table 2.9. Description of reaches surveyed for sockeye salmon carcasses and live fish in the Wenatchee River basin during survey years 1993-2013.

| Stream | Code | Reach | River mile (RM) |
| :---: | :---: | :---: | :---: |
| Little Wenatchee River | L1 | Mouth to Old Fish Weir | $0.0-2.7$ |
|  | L2 | Old Fish Weir to Lost Creek | $2.7-5.2$ |
|  | L3 | Lost Creek to Rainy Creek | $5.2-9.2$ |
|  | H1 | Mouth to Sears Creek Bridge | $0.0-6.4$ |

| Napeequa River | Q1 | Mouth to End | $0.0-1.0$ |

Wenatchee summer Chinook redd and carcass surveys were conducted from September through November throughout the entire mainstem Wenatchee River, which was divided into ten reaches (Table 2.10). Surveys were conducted weekly in all reaches. All redds were enumerated during weekly census counts.

Table 2.10. Description of reaches surveyed for summer Chinook redds in the Wenatchee River basin.

| Code | Reach | River mile |
| :---: | :---: | :---: |
| W1 | Mouth to Sleepy Hollow Br | $0.0-3.3$ |
| W2 | Sleepy Hollow Br to L. Cashmere Br | $3.3-9.5$ |

| W10 | Tumwater Br to Chiwawa River | $35.6-47.9$ |
| Chiwawa River to Lake Wenatchee | $47.9-54.2$ |  |

Summer Chinook redd and carcass surveys were also conducted in the Methow and Chelan rivers from September through November. Total (map) redd counts were conducted in these rivers. Table 2.11 describes the survey reaches on the Methow River. The Colville Tribes conducted summer Chinook redd and carcass surveys in the Okanogan River basin. Those results are reported in a separate report (annual report to BPA).

Table 2.11. Description of reaches surveyed for summer Chinook redds and carcasses on the Methow, Okanogan, and Similkameen rivers.

| Stream | Code | Reach | River mile (RM) |
| :---: | :---: | :---: | :---: |
| Methow River | M1 | Mouth to Methow Bridge | $0.0-14.8$ |
|  | M2 | Methow Bridge to Carlton Bridge | $14.8-27.2$ |
|  | M3 | Carlton Bridge to Twisp Bridge | $27.2-39.6$ |
|  | M4 | Twisp Bridge to MVID | $39.6-44.9$ |
|  | M5 | MVID to Winthrop Bridge | $44.9-49.8$ |
|  | Okanogan River | M6 | Winthrop Bridge to Hatchery Dam |

|  | O2 | Mallot Bridge to Okanogan Bridge | $0.0-16.9$ |
|  | O3 | Okanogan Bridge to Omak Bridge | $16.9-26.1$ |
|  | O4 | Omak Bridge to Riverside Bridge | $26.1-30.7$ |
|  | O5 | Riverside Bridge to Tonasket Bridge | $30.7-40.7$ |
|  | O6 | Tonasket Bridge to Zosel Dam | $40.7-56.8$ |
| Similkameen River | S1 | Driscoll Channel to Oroville Bridge | $56.8-77.4$ |
|  | S2 | Oroville Bridge to Enloe Dam | $0.0-1.8$ |

For summer and spring Chinook, total spawning escapements for each population were estimated as the product of total number of redds times the ratio of fish per redd for a specific stock. ${ }^{3}$ Fish per redd ratios were estimated as the ratio of males to females sampled at broodstock collection sites and monitoring sites (e.g., Leavenworth National Fish Hatchery, Dryden Dam, Tumwater Dam, Chiwawa Weir, etc.). For steelhead, spawning escapement was estimated with a combination of PIT-tag-based tributary and redd-based mainstem Wenatchee River estimates. Total spawning escapement for sockeye salmon in the Little Wenatchee and White River watersheds was estimated using mark-recapture methods. Adult sockeye were PIT tagged at Tumwater Dam and Bonneville Dam ${ }^{4}$ and detected in the Little Wenatchee and White rivers with stationary PIT-tag interrogation systems.

Derived metrics calculated from carcass surveys, broodstock sampling, stock assessments, and harvest records included proportion of hatchery spawners, stray rates, age-at-maturity, length-atage, smolt-to-adult survival (SAR), hatchery replacement rates (HRR), harvest rates, and natural replacement rates (NRR). The target HRRs (from Hillman et al. 2013) for different stocks raised in the PUD hatchery programs are provided in Table 2.12. Methods for calculating derived variables are described in Hillman et al. (2013) and in "White Papers" developed by the Hatchery Evaluation Technical Team (HETT) (see Appendices in Hillman et al. 2012). The abundance of hatchery and natural-origin Chinook salmon spawners was based upon the proportion of carcasses by origin that were collected on the spawning grounds.

[^2]Table 2.12. Hatchery replacement rate (HRR) targets for stocks raised in the PUD Hatchery Programs.

| Program | Number of broodstock | Smolts released | HRR targets |
| :--- | :---: | :---: | :---: |
| Chiwawa Spring Chinook | 74 | 144,026 | 6.7 |
| Nason Creek Spring Chinook | 66 | 125,000 | 6.7 |
| Wenatchee Summer Chinook | 278 | 500,001 | 5.7 |
| Methow Summer Chinook | 100 | 200,000 | 3.0 |
| Wenatchee Steelhead | 130 | 247,300 | 6.9 |

Derived data that rely on CWTs (e.g., HRR, SAR, stray rates, etc.) are five or more years behind release information because of the lag time for returning adult fish to enter the fishery and spawning grounds, and the processing of tags. Consequently, complete information on rates and ratios based on CWTs is generally only available for brood years before 2010.

## SECTION 3: WENATCHEE STEELHEAD

The goal of summer steelhead supplementation in the Wenatchee Basin is to use artificial production to replace adult production lost because of mortality at Rock Island and Rocky Reach dams, as well as inundation compensation for Rocky Reach Dam, while not reducing the natural production or long-term fitness of steelhead in the basin. The Rock Island Fish Hatchery Complex began operation in 1989 under funding from Chelan PUD. The Complex operated originally through the Rock Island Settlement Agreement, but since 2004 has operated under the Rock Island and Rocky Reach Anadromous Fish Agreement and Habitat Conservation Plans.

Prior to 1998, steelhead eggs were received from Wells Hatchery (adult broodstock were collected at Wells Dam); fish were reared at Eastbank Fish Hatchery and then released into the Wenatchee River. Beginning in 1998, the program changed to collecting broodstock within the Wenatchee Basin. Currently, adult hatchery steelhead are collected from the run-at-large at the right and leftbank traps at Dryden Dam, and at Tumwater Dam if the weekly quotas cannot be achieved at Dryden Dam. Natural-origin (WxW) adult steelhead are collected from the run-at-large at Tumwater and Dryden dams if the weekly quotas cannot be achieved at Dryden Dam.
Before 2012, the goal was to collect up to 208 adult steelhead ( $50 \%$ natural-origin fish and $50 \%$ hatchery-origin fish) for the Wenatchee steelhead program. In 2011, the Hatchery Committees reevaluated the amount of hatchery compensation needed to achieve NNI. Based on that evaluation, the goal of the program was revised. The current goal (which began in 2012) is to collect 130 adult steelhead ( 64 natural-origin and 66 hatchery-origin fish) for a 247,300 smolt program, but the number of broodstock collected cannot exceed $33 \%$ of the natural Wenatchee steelhead population. Broodstock collection occurs from about 1 July through 15 November at Dryden and Tumwater dams, with trapping occurring up to 24 hours per day, five days a week. The intent of the current program is to target adults necessary to meet a $50 \%$ natural-origin, conservation-oriented program and a $50 \%$ hatchery-origin safety-net program.
Before the 2012 brood year, adult steelhead were held and spawned at Wells Fish Hatchery because of unsuitable adult holding temperatures at Eastbank Fish Hatchery. Beginning with the 2012 brood year, adult steelhead holding and spawning have occurred at Eastbank Fish Hatchery with the installation of a water chiller system. Before 2012, juvenile steelhead were reared at a combination of facilities including Eastbank, Chelan, Turtle Rock, Rocky Reach Annex, and Chiwawa facilities. Juvenile steelhead reared in these facilities were trucked to release locations on the Wenatchee River, Chiwawa River, and Nason Creek. A percentage of the fish have also been released volitionally from Blackbird Pond and Rolfing Pond. Beginning in the fall of 2012, the entire Wenatchee steelhead program overwinters at the Chiwawa Acclimation Facility. Some of these fish are transferred to short-term remote acclimation sites (e.g., Blackbird Pond and Rolfing Pond), while others are planted from trucks throughout the Wenatchee, Nason, and Chiwawa basins.

Before 2012, the production goal for the Wenatchee steelhead supplementation program was to release 400,000 yearling smolts into the Wenatchee Basin at six fish per pound. Since 2012, the revised production goal is to release 247,300 smolts ( 123,650 for conservation and 123,650 for safety net). Targets for fork length and weight are $191 \mathrm{~mm}(\mathrm{CV}=9.0)$ and 75.6 g , respectively; the target size at release is six fish per pound. Over $96 \%$ of these fish receive CWTs. In addition,
since 2006, juvenile steelhead from different parental-cross groups (e.g., WxW, HxW, and HxH) have been PIT tagged annually. No HxW crosses have occurred since brood year 2009.

Beginning in 2010 and consistent with ESA Section 10(a)(1)(A) permit 1395, adult management activities have been conducted to remove excess hatchery-origin steelhead before they spawn in the natural environment. This is accomplished through removal at Tumwater Dam and/or through conservation fisheries. The objective of these activities is to achieve proportion of hatchery-origin spawners ( pHOS ) and Proportionate Natural Influence (PNI) goals for the Wenatchee steelhead program. Results of adult management activities are submitted to NOAA Fisheries in a separate annual report by 31 August of the year the adult management was concluded.

### 3.1 Broodstock Sampling

This section focuses on results from sampling 2015 and 2016 brood years of Wenatchee steelhead, which were collected at Dryden and Tumwater dams. The 2015 brood begins the tracking of the life cycle of steelhead released in 2016. The 2016 brood is included because juveniles from this brood are still maintained within the hatchery.

## Origin of Broodstock

A total of 136 Wenatchee steelhead from the 2014 return ( 2015 brood) were collected at Dryden and Tumwater dams (Table 3.1). About $56 \%$ of these were natural-origin (adipose fin present and no CWT) fish and the remaining $44 \%$ were hatchery-origin (CWT and adipose fin present) adults. Origin was determined by analyzing scales and/or otoliths. The total number of steelhead spawned from the 2015 brood was 110 adults ( $52.7 \%$ natural-origin and $47.3 \%$ hatchery-origin).
A total of 132 steelhead were collected from the 2015 return (2016 brood) at Dryden and Tumwater dams; 67 (50.8\%) natural-origin (adipose fin present and no CWT) and 66 (45.5\%) hatchery-origin (CWT and adipose fin present) adults. A total of 132 steelhead were spawned; $50 \%$ were naturalorigin fish and $50 \%$ were hatchery fish (Table 3.1). Origin was confirmed by sampling scales and/or otoliths.

Table 3.1. Numbers of wild and hatchery steelhead collected for broodstock, numbers that died before spawning, and numbers of steelhead spawned, 1998-2016. Unknown origin fish (i.e., undetermined by scale analysis, no elastomer, no CWT, no fin clips, and no additional hatchery marks) were considered naturally produced. Mortality includes fish killed at spawning and surplus broodstock.

| Brood year | Wild steelhead |  |  |  |  | Hatchery steelhead |  |  |  |  | Total number spawned |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

${ }^{\text {a }}$ Pre-spawn loss represents the number of fish that died during the holding period before spawning. Mortality is the number of fish that were surplused following spawning.
${ }^{\mathrm{b}}$ This average and median represent the program before recalculation in 2011.
${ }^{\mathrm{c}}$ This average and median represent the current program, which began in 2012.

## Age/Length Data

Broodstock ages were determined from examination of scales and/or otoliths. For the 2015 brood year, natural-origin steelhead consisted primarily of 2 -salt adults, while hatchery steelhead consisted almost equally of 1 and 2-salt adults (Table 3.2). For the 2016 brood year, natural and hatchery-origin steelhead consisted primarily of 2-salt adults (Table 3.2).
Table 3.2. Percent of hatchery and wild steelhead of different ages (saltwater ages) collected from broodstock, 1998-2016.

There was little difference between mean lengths of hatchery and natural-origin steelhead in the 2015 and 2016 brood years (Table 3.3). Natural-origin fish were on average 1 to 3 cm larger than hatchery-origin fish of the same age.

## Sex Ratios

Male steelhead in the 2015 brood year made up about $50 \%$ of the adults collected, resulting in an overall male to female ratio of 1.00:1.00 (Table 3.4). For the 2016 brood year, males made up about $50.4 \%$ of the adults collected, resulting in an overall male to female ratio of 1.02:1.00. On average (1998-2016), the sex ratio is slightly less than the $1: 1$ ratio assumed in the broodstock protocol (Table 3.4).
Table 3.4. Numbers of male and female wild and hatchery steelhead collected for broodstock, 1998-2016. Ratios of males to females are also provided.

| Brood year | Number of wild steelhead |  |  | Number of hatchery steelhead |  |  | Total M/F ratio |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## Fecundity

Fecundities for Wenatchee steelhead in brood years 2015 and 2016 averaged 5,895 and 5,174 eggs per female, respectively (Table 3.5). Mean fecundity for the 2015 brood year was greater while the 2016 brood year was less than the 5,678 eggs per female assumed in the broodstock protocol.

Table 3.5. Mean fecundity of wild, hatchery, and all female steelhead collected for broodstock, 1998-2016.

| Brood year | Mean fecundity |  |  |
| :---: | :---: | :---: | :---: |

| Median | 5,776 | 5,558 | 5,781 |
|  |  |  |  |

### 3.2 Hatchery Rearing

## Rearing History

## Number of eggs taken

From 1998-2011, a total of 493,827 eggs were required to meet the program release goal of 400,000 smolts. This was based on the unfertilized egg-to-release survival standard of $81 \%$. In 2012, the egg take target was reduced to 305,309 , which is needed to meet the revised release target of 247,300 smolts. Between 1998 and 2011, the egg take goal was reached $57 \%$ of the time (Table 3.6). Since 2011, the target has been reached or exceeded $100 \%$ of the time (Table 3.6).
Table 3.6. Numbers of eggs taken from steelhead broodstock, 1998-2016.

| Brood year | Number of eggs taken |
| :---: | :---: |
| 1998 | 224,315 |
| 1999 | 303,083 |

| Average (2012-present) | 354,455 |
| Median (2012-present) | 341,511 |

## Number of acclimation days

Juvenile WxW steelhead from the Chelan Fish Hatchery and HxH steelhead from the Eastbank Fish Hatchery were transferred to Chiwawa Acclimation Facility in November 2015. In March 2016, about $25,000 \mathrm{HxH}$ steelhead were transferred from the Chiwawa Acclimation Facility to Blackbird Pond near Leavenworth for final acclimation on Wenatchee River water. Fish were acclimated for 23 d at Blackbird Pond before a volitional release was initiated on 20 April. The remainder stayed at the Chiwawa Acclimation Facility until they were volitionally and forced released from the facility during late April to early-May.

Juvenile Wenatchee steelhead at the Chiwawa Acclimation Facility were acclimated and reared on Wenatchee and Chiwawa River water. Before 2012, Wenatchee steelhead were reared on Columbia River water from January through May before being trucked and released into the Wenatchee River basin (Table 3.7).
Table 3.7. Water source and mean acclimation period for Wenatchee steelhead, brood years 1998-2016.

| Brood year | Release year | Parental origin | Water source | Number of Days |

${ }^{\text {a }}$ Steelhead overwintered in Pond 3 at the Chiwawa Acclimation Facility on Chiwawa River water before they were transferred to Blackbird Pond.

## Release Information

## Numbers released

In 2011, the HCP Hatchery Committee agreed to reduce the Wenatchee summer steelhead program from 400,000 smolts to 247,300 smolts. Based on this new goal and the number of WxW steelhead present, all HxH steelhead were transferred to the Ringold Fish Hatchery to be included in their production program for the 2012 release.

The release of 2015 brood Wenatchee steelhead achieved $79 \%$ of the 247,300 target with about 195,344 smolts released into the Wenatchee and Chiwawa rivers and Nason Creek (Table 3.8). Distribution of juvenile steelhead released in each of the three streams was determined by the mean proportion of steelhead redds in each basin. About $28.2 \%$ and $19.3 \%$ of the steelhead were released in Nason Creek and the Chiwawa River, respectively. The balance of the program was split between the Wenatchee River downstream from Tumwater Dam (10.9\%) and the Wenatchee River upstream from the dam (41.5\%).

Table 3.8. Numbers of steelhead smolts released from the hatchery, brood years 1998-2015. Before brood year 2011, the release target for steelhead was 400,000 smolts. Beginning with brood year 2011, the release target is 247,300 smolts.

## Numbers marked

Wenatchee hatchery steelhead from the 2015 brood were marked with coded wire tags (CWT) in the snout. About $44.9 \%$ of the juveniles released were also adipose fin clipped (Table 9).

Table 3.9. Release location and marking scheme for the 1998-2015 brood Wenatchee steelhead.

| 2014 | Wenatchee/Chiwawa/Nason | WxW | 9,051 | 53 | 0 | 8,998 |
|  | Wenatchee/Chiwawa/Nason | HxH | 10,129 | 243 | 76 | 9,810 |
| 2015 | Wenatchee/Chiwawa/Nason | WxW | 12,101 | 60 | 0 | 12,041 |
|  | Wenatchee/Chiwawa/Nason | HxH | 11,115 | 55 | 0 | 11,060 |

2016 Brood Wenatchee WxW Summer Steelhead (Circular Ponds)—A total of 5,050 Wenatchee WxW summer steelhead were PIT tagged at the Chiwawa Acclimation Facility on 23-24 February 2017. These fish were tagged in circular ponds \#1 and \#3. Fish were not fed during tagging or for two days before and after tagging. Fish averaged 141-149 mm in length and 29-38 g at time of tagging.

2016 Brood Wenatchee HxH and WxW Summer Steelhead (Raceway)—A total of 12,626 Wenatchee HxH and WxW summer steelhead were PIT tagged at the Chiwawa Acclimation Facility on 27 February to 3 March 2017. These fish were tagged in raceway \#2. Fish were not fed during tagging or for two days before and after tagging. Fish averaged $129-130 \mathrm{~mm}$ in length and $22-26 \mathrm{~g}$ at time of tagging.

2016 Brood Wenatchee Summer Steelhead (Blackbird Pond)—A total of 2,525 Wenatchee summer steelhead destined for Blackbird Pond were PIT tagged at the Chiwawa Acclimation Facility on 21-22 February 2017. These fish were tagged in raceway \#3. Fish were not fed during tagging or for two days before and after tagging. Fish averaged 133 mm in length and 25 g at time of tagging.

## Fish size and condition at release

Except for the Blackbird Pond release, all 2015 brood steelhead were trucked and released as yearling smolts in April and May 2016. The Blackbird Pond group was released volitionally beginning on 20 April. Both WxW and HxH fish did not meet the targets for length, weight, or coefficient of variation (CV) for fork length (Table 3.11). The HxH group was combined with the WxW group in Pond 2 once they were transferred to Chiwawa Acclimation Facility. The HxH fish were larger than the WxW fish at the time of transfer but smaller at the time of release.

Table 3.11. Mean lengths (FL, mm), weight ( g and fish/pound), and coefficient of variation (CV) of steelhead smolts released from the hatchery, brood years 1998-2015. Size targets are provided in the last row of the table.

## Survival Estimates

Overall survival of Wenatchee steelhead (WxW and HxH ) from green (unfertilized) egg to release was below the standard set for the program. This is largely because of lower unfertilized egg to eyed egg survival (Table 3.12).
The Wenatchee steelhead program, from its inception, has experienced highly variable fertilization rates. It is unknown at this time what mechanisms may be influencing stock performance at these stages.
Table 3.12. Hatchery life-stage survival rates (\%) for steelhead, brood years 1998-2015. Survival standards or targets are provided in the last row of the table.

| Brood year | Collection to <br> spawning |  | Unfertilized <br> egg-eyed | Eyed <br> egg- <br> ponding | $\mathbf{3 0 d}$ <br> after <br> ponding | $\mathbf{1 0 0} \mathbf{d}$ <br> after <br> ponding | Ponding <br> to <br> release | Transport <br> to release | Unfertilized <br> egg-release |

${ }^{a}$ Survival estimates are only for WxW steelhead.

### 3.3 Disease Monitoring

Rearing of the 2015 brood Wenatchee summer steelhead was similar to previous years with fish being held on Chelan spring water, Eastbank well water, and Chelan well water before being transferred for overwinter acclimation at the Chiwawa Acclimation Facility. Volitional and forcereleased fish were released into Nason Creek, Chiwawa River, and the Wenatchee River. The 2015 WxW Wenatchee steelhead had no significant health issues during the rearing period.

### 3.4 Natural Juvenile Productivity

During 2016, juvenile steelhead were sampled at the Lower Wenatchee, Chiwawa, and Nason Creek traps and counted during snorkel surveys within the Chiwawa River basin. Because the snorkel surveys targeted juvenile Chinook salmon, the entire distribution of juvenile steelhead in the Chiwawa River basin was not surveyed. Therefore, the parr numbers presented below represent a minimum estimate.

## Parr Estimates

A total of $16,244( \pm 14 \%)$ age- $0(<100 \mathrm{~mm})$ and $4,031( \pm 15 \%)$ age- $1+(100-200 \mathrm{~mm})^{5}$ steelhead/rainbow were estimated in the Chiwawa River basin in August 2016 (Table 3.13 and 3.14). During the survey period 1992-2016, numbers of age-0 and $1+$ steelhead/rainbow have ranged from 1,410 to 45,727 and 754 to 22,130, respectively, in the Chiwawa River basin (Table 3.13 and 3.14; Figure 3.1). Numbers of all fish counted in the Chiwawa River basin are reported in Appendix A.

Juvenile steelhead/rainbow were distributed primarily throughout the lower seven reaches of the Chiwawa River (downstream from Rock Creek). Their densities were highest in the lower portions of the river and in tributaries. Age-0 steelhead/rainbow most often used riffle and multiple channel habitats in the Chiwawa River, although they also associated with woody debris in pool and glide habitat. In tributaries, they were generally most abundant in small pools. Those that were observed in riffles selected stations in quiet water behind small and large boulders, or occupied stations in quiet water along the stream margin. In pool and multiple-channel habitats, age-0 steelhead/rainbow used the same kinds of habitat as age-0 Chinook salmon.
Age-1+ steelhead/rainbow most often used pool, riffle, and multiple-channel habitats. Those that used pools were usually in deeper water than subyearling steelhead/rainbow and Chinook salmon. Like age-0 steelhead/rainbow, age-1+ steelhead/rainbow generally selected stations in quiet water behind boulders in riffles, but the two age groups rarely occurred together. Age-1+ steelhead/rainbow used deeper and faster water than did subyearling steelhead/rainbow.

5 A steelhead/rainbow trout larger than $200 \mathrm{~mm}(8 \mathrm{in})$ was considered a resident trout.

Table 3.13. Total numbers of age-0 steelhead/rainbow trout estimated in different steams in the Chiwawa River basin during snorkel surveys in August 1992-2016; NS = not sampled.

## Steelhead/Rainbow <br> Age-0

Age-1+

Figure 3.1. Numbers of subyearling and yearling steelhead/rainbow trout within the Chiwawa River basin in August 1992-2016; ND = no data.

## Emigrant and Smolt Estimates

Numbers of steelhead smolts and emigrants were estimated at the Chiwawa, Nason, and Lower Wenatchee traps in 2016.

## Chiwawa Trap

The Chiwawa Trap operated between 2 March and 21 November 2016. During the trapping period, the trap was inoperable for 72 days due to high or low river discharge, debris, major hatchery releases, and mechanical issues. The trap operated in a single position throughout the sampling season. Monthly captures of all fish collected at the Chiwawa Trap are reported in Appendix B.
A total of 195 wild steelhead/rainbow smolts, 1,518 hatchery smolts, and 1,522 wild parr and fry were captured at the Chiwawa Trap. Most (99\%) of the hatchery steelhead were collected in May, while most ( $75 \%$ ) of the wild steelhead smolts were captured in April through June (Figure 3.2). Although steelhead/rainbow parr and fry emigrated throughout the sampling period, peaks in emigration were observed in April through June and in October (Figure 3.2). Of the total number of wild steelhead captured, $87 \%$ were classified as parr and fry. Three mark-recapture efficiency trials were conducted with a pooled trap efficiency of $8.1 \%$.

## Juvenile Steelhead

Figure 3.2. Monthly captures of wild smolts, wild parr, and hatchery smolt steelhead/rainbow at the Chiwawa Trap, 2016.

## Nason Creek Trap

The Nason Creek Trap operated between 1 March and 30 November 2016. During the nine-month sampling period the trap was inoperable for 62 days because of low discharge and flooding. The trap captured a total of 9 wild steelhead smolts, 98 hatchery steelhead smolts, 663 wild steelhead parr, and 335 wild steelhead fry. The estimated wild steelhead emigration for brood year 2013 was

13,417 ( $\pm 9,133$ ). Egg-to-emigrant survival rate for brood year 2012 steelhead was $1.7 \%$ and the egg-to-emigrant survival rate for brood year 2012 was $3.0 \%$. Productivity, measured as emigrants-per-redd, was 99.

## Lower Wenatchee Trap

The Lower Wenatchee Trap operated between 29 January and 26 June 2016. During that time, the trap was inoperable for 23 days because of too high and low river discharge, debris, elevated river temperatures, large hatchery releases, and mechanical issues. During the sampling period, a total of 329 wild steelhead parr and fry, 88 wild steelhead smolts, and 259 hatchery steelhead were captured at the trap. Because of the low numbers of steelhead encountered at the trap, it was not possible to carry out mark-recapture trials using steelhead. In addition, because there was a poor relationship between trap efficiency and river flow, a pooled estimate was used to derive the number of steelhead emigrants. Using this pooled method, it was estimated that $10,135( \pm 102,145)$ steelhead $>50 \mathrm{~mm}$ FL emigrated out of the Wenatchee during the trapping season. Figure 3.3 shows the monthly captures of all steelhead collected at the Lower Wenatchee Trap. All fish captured in the trap are reported in Appendix B.

## Juvenile Steelhead

Figure 3.3. Monthly captures of wild smolts, wild parr, and hatchery smolt steelhead/rainbow at the Lower Wenatchee Trap, 2016.

## PIT Tagging Activities

As part of the Comparative Survival Study (CSS) and PUD studies, a total of 1,980 juvenile steelhead/rainbow trout ( 1,979 wild and one hatchery) were PIT tagged and released in 2016 in the Wenatchee River basin (Table 3.15a). Most of these were tagged at the Chiwawa Trap. See Appendix C for a complete list of all fish captured, tagged, lost, and released.

Table 3.15a. Numbers of wild and hatchery steelhead/rainbow trout that were captured, tagged, and released at different locations within the Wenatchee River basin, 2016. Numbers of fish that died or shed tags are also given.

${ }^{1} 2013$ was the last year that the Upper Wenatchee Trap operated.

### 3.5 Spawning Surveys

Surveys for steelhead redds were conducted during March through early June 2016, in the mainstem Wenatchee River and portions of select tributaries (Chiwawa River, Nason Creek, and Peshastin Creek). Beginning in 2014, adult steelhead escapement estimates in the majority of tributaries in the Wenatchee River basin were generated using mark-recapture techniques based on steelhead PIT tagged at Priest Rapids Dam (BPA funded; see Appendix D and Truscott et al. 2016 for details).

## Redd Counts

A total estimate of 126 steelhead redds were counted in the Wenatchee River and the lower portions of select tributaries in 2016 (Table 3.16). Because steelhead escapement estimates in tributaries are based on mark-recapture techniques, there are no or limited redd counts in tributaries beginning in 2014. Additionally, mainstem redd counts since 2014 were expanded based on
estimates of observer efficiency (see Appendix D). Thus, evaluation of trends in redd counts is appropriate only before 2014.
Table 3.16. Numbers of steelhead redds estimated within different streams/watersheds within the Wenatchee River basin, 2001-2016; NS = not surveyed. Redd counts from 2004-2013 have been conducted within the same areas and with the same methods. Beginning in 2014, complete redd counts were conducted only within the mainstem Wenatchee River. Therefore, trends in redd counts are only appropriate for the mainstem Wenatchee River from 2004 through 2013.

| Survey <br> year | Number of steelhead redds |  |  |  |  |  |  |  |

${ }^{\text {a }}$ Includes redds in Beaver and Chiwaukum creeks.
${ }^{\mathrm{b}}$ Steelhead redd counts in the mainstem Wenatchee River were expanded based on estimated observer efficiency (see Appendix D).

## Redd Distribution

Steelhead redds were not evenly distributed among survey reaches on the Wenatchee River in 2016 (Table 3.17). About $91.3 \%$ of the spawning in the Wenatchee River occurred upstream from Tumwater Dam (Table 3.17).

Table 3.17. Numbers and percentages of steelhead redds counted within different reaches on the Wenatchee River during March through early June, 2016; CV = coefficient of variation, NA = not available, NS = not surveyed.

| Total |  | 112 | 126 | 1.04 | 100.0 |

## Spawn Timing

Steelhead began spawning during the second week of March in the Wenatchee River. Spawning activity appeared to begin once the mean daily stream temperature reached about $5.5^{\circ} \mathrm{C}$ and was observed in water temperatures ranging from $3.7-8.8^{\circ} \mathrm{C}$. Steelhead spawning peaked during the third week of April in the Wenatchee River (Figure 3.4).

Steelhead Redds

Figure 3.4. Numbers of steelhead redds counted during different weeks on the Wenatchee River, March through early June 2016.

## Spawning Escapement

Before 2014, steelhead spawning escapement upstream from Tumwater Dam was calculated as the number of redds (in the Wenatchee River and tributaries upstream from the dam) times the fish per redd ratio (based on sex ratios estimated at Tumwater Dam using video surveillance). ${ }^{6}$ Beginning in 2014, escapement in tributaries was estimated using PIT-tag mark-recapture techniques (Truscott et al. 2016; Table 3.18), while observer efficiency expanded redd counts were used to estimate escapement in the mainstem Wenatchee River (Appendix D). Total redd counts were also used to estimate escapement in the lower portions of the main tributaries (downstream from the PIT interrogation sites).

Table 3.18. Spawning escapement estimates for natural-origin and hatchery-origin steelhead within tributaries of the Wenatchee River, brood year 2016. Escapement estimates were based on PIT-tag markrecapture techniques (Truscott et al. 2016). CV = coefficient of variation and NA $=$ not available.

| Tributary | Natural-origin steelhead |  | Hatchery-origin steelhead |  |
| :---: | :---: | :---: | :---: | :---: |
|  | Estimate | $\mathbf{C V}$ | Estimate | $\mathbf{C V}$ |
| Mission Creek | 33 | 0.38 | 13 | 0.69 |
| Peshastin Creek | 151 | 0.19 | 0 | NA |
| Chumstick Creek | 74 | 0.27 | 39 | 0.37 |
| Icicle Creek | 72 | 0.25 | 18 | 0.53 |
| Chiwaukum Creek | 64 | 0.36 | 11 | 1.00 |
| Chiwawa River | 45 | 0.44 | 134 | 0.35 |
| Nason Creek | 57 | 0.39 | 94 | 0.32 |

The estimated fish per redd ratio for steelhead in 2016 was 1.65 (Table 3.19). Multiplying this ratio by the total number of redds estimated in the Wenatchee River upstream from Tumwater Dam resulted in a spawning escapement of 167 steelhead (Table 3.19). Adding this estimate to the mark-recapture estimates of tributary escapement ( 239 hatchery +166 wild $=405$ ) indicates that $572(\mathrm{CV}=0.167)$ escaped to spawning areas upstream from Tumwater Dam in 2016 (see Appendix D).
Table 3.19. Numbers of steelhead counted at Tumwater Dam, fish/redd estimates (based on male-to-female ratios estimated at Tumwater Dam), numbers of steelhead redds counted upstream from Tumwater Dam, total spawning escapement upstream from Tumwater Dam (estimated as the total number of redds times the fish/redd ratio), and the proportion of the Tumwater Dam count that made up the spawning escapement. Beginning in 2014, escapements include estimates from redd counts in the Wenatchee River and markrecapture techniques in tributaries.

${ }^{\text {a }}$ Escapement estimates before 2014 were based on expanded redd counts in the Wenatchee River and tributaries; escapement estimates beginning in 2014 were based on expanded redd counts within the Wenatchee River and mark-recapture techniques in tributaries.
${ }^{\mathrm{b}}$ The average and median are based on estimates from 2004 to 2013.
${ }^{\text {c }}$ The average and median are based on estimates from 2014 to present.

### 3.6 Life History Monitoring

Life history characteristics of steelhead were assessed by examining fish collected at broodstock collection sites, examining videotape at Tumwater Dam, and by reviewing tagging data and fisheries statistics. Before brood year 2011, some statistics could not be calculated because few steelhead were tagged with CWTs. Since brood year 2011, all steelhead released from the hatchery program have been tagged with CWTs. In addition, about 23,101 of the 2015 brood were PIT tagged. With the placement of remote PIT tag detectors in spawning streams in 2007 and 2008, statistics such as origin on spawning grounds, stray rates, and SARs can be estimated more accurately.

## Migration Timing

Sampling at Tumwater Dam indicates that steelhead migrate throughout the year; however, the migration distribution is bimodal, indicating that steelhead migrate past Tumwater Dam in two pulses: one pulse during summer-autumn the year before spawning and another during winterspring the year of spawning (Figure 3.5). Most steelhead passed Tumwater Dam during July through October and April. The highest proportion of both wild and hatchery fish migrated during October.

## Steelhead Migration Timing

Figure 3.5. Proportion of wild and hatchery steelhead sampled at Tumwater Dam for the combined brood years of 1999-2016.
Because the migration of steelhead is bimodal, we estimated migration statistics separately for each migration pulse (i.e., summer-autumn migration and winter-spring migration). That is, we compared migration statistics for wild and hatchery steelhead passing Tumwater Dam during the summer-autumn period independent of those for the winter-spring migration period. We estimated the week and month that $10 \%, 50 \%$ (median), and $90 \%$ of the wild and hatchery steelhead passed Tumwater Dam during the two migration periods. We also estimated the mean weekly and monthly migration timing for wild and hatchery steelhead.
Migration timing of wild and hatchery fish at Tumwater Dam varied depending on the migration season (Table 3.20a and b; Figure 3.5). For the summer-autumn migration period, wild steelhead arrived at the dam about one week earlier than hatchery steelhead. In contrast, there was little difference in migration timing of wild and hatchery steelhead during the winter-spring migration period.

Table 3.20a. The week that $10 \%, 50 \%$ (median), and $90 \%$ of the wild and hatchery steelhead passed Tumwater Dam during their summer-autumn migration (June through December) and during their winterspring migration (January through May), 1999-2016. The average week is also provided for both migration periods. Migration timing is based on video sampling at Tumwater. The presence of eroded fins and/or missing adipose fins was used to distinguish hatchery fish from wild fish during video monitoring at Tumwater Dam. Estimates also include steelhead collected for broodstock.

## Age at Maturity

Nearly all steelhead broodstock collected at Tumwater and Dryden dams lived in saltwater 1 to 2 years (saltwater age) (Table 3.21). Very few saltwater age- 3 fish returned and those that did were wild fish. On average, there was a difference between the saltwater age at return of wild and hatchery fish. A greater proportion of hatchery fish returned as saltwater age-1 fish than did wild fish. In contrast, a greater number of wild fish returned as saltwater-2 fish than did hatchery fish (Figure 3.6).
Table 3.21. Proportions of wild and hatchery steelhead broodstock of different ages collected at Tumwater and Dryden dams, brood years 1998-2016. Age represents the number of years the fish lived in salt water.

| Brood year | Origin | Saltwater age |  |  | Sample size |

## Steelhead Age Structure

Figure 3.6. Proportions of wild and hatchery steelhead of different saltwater ages sampled at Tumwater Dam for the combined years 1998-2016.

## Size at Maturity

On average, hatchery steelhead collected at Tumwater and Dryden dams were about 2 to 3 cm smaller than wild steelhead (Table 3.22).

Table 3.22. Mean fork length (cm) at age (saltwater ages) of hatchery and wild steelhead collected from broodstock, brood years 1998-2016; $\mathrm{N}=$ sample size and $\mathrm{SD}=1$ standard deviation.

## Contribution to Fisheries

Nearly all harvest on Wenatchee steelhead occurs within the Columbia basin. Harvest rates on steelhead in the Lower Columbia River fisheries (both tribal and non-tribal) are generally less than 5-10\% (NMFS 2004). A sport fishery may be opened on Upper Columbia River steelhead when the natural-origin steelhead run is predicted to exceed 1,300 fish at Priest Rapids Dam and the total Upper Columbia River steelhead run is predicted to exceed 9,550 steelhead. To minimize effects on natural-origin steelhead in the tributary fisheries, a three-tiered system as outlined in Permit 1395 is used to determine maximum allowable natural-origin steelhead take during the fishery (Table 3.23a).
Table 3.23a. Three-tiered system for determining natural-origin effects during the recreational fishery on steelhead in tributaries upstream from Rock Island Dam.

| Tier | Wenatchee |  | Methow |  | Okanogan |  |

${ }^{1 .}$ Estimated natural-origin escapement to tributaries.
${ }^{2 .}$ Maximum allowable take on natural-origin fish.
WDFW implemented a selective recreational steelhead fishery in the upper Columbia River during fall 2015 through winter 2016 (Table 3.23b). The fishery was conducted as a conservation measure to reduce the proportion of hatchery-origin steelhead on the spawning grounds. There were 56 hatchery steelhead harvested and an additional eight wild steelhead hook-and-release mortalities estimated for the Wenatchee River basin. Over the eight years that the Wenatchee River had a recreational fishery, average harvest has been about 183 hatchery steelhead and 16 wild steelhead hook-and-release mortalities. In the mixed population fishery within the mainstem Columbia from Priest Rapids Dam to Chief Joseph Dam, the average harvest of hatchery steelhead has been 861steelhead with 17 wild hook-and-release mortalities.

Table 3.23b. Harvest and mortality estimates for Upper Columbia steelhead in the Wenatchee and mainstem Columbia River (Priest Rapids Dam to Chief Joseph Dam). Estimated steelhead sport harvest on Wenatchee hatchery steelhead and hook-and-release mortality on wild steelhead (WDFW 2016). The wild steelhead mortality estimate is based on a hook-and-release mortality rate of $5 \%$. Mainstem harvest from Priest Rapids Dam to Chief Joseph Dam is a mixed-population steelhead fishery that may contain fish from the Wenatchee, Entiat, Methow, and Okanogan rivers.

## Origin on Spawning Grounds

With the implementation of PIT-tag mark-recapture techniques in 2014, we can estimate the contribution of natural-origin and hatchery-origin fish on the spawning grounds (Table 3.24). Based on mark-recapture estimates, naturally produced steelhead made up about $60.6 \%$ of the escapement in 2016. Importantly, the abundance of hatchery fish in the upper Wenatchee Basin was regulated through surplusing (removal) at Tumwater Dam. A total of 290 hatchery steelhead were surplused at the dam resulting in the passage of 1,025 steelhead over the dam in 2016. Natural-origin steelhead comprised $59.4 \% ~(~ N=609) ~ o f ~ t h e ~ s t e e l h e a d ~ t h a t ~ p a s s e d ~ t h e ~ d a m . ~$
Table 3.24. Spawning escapement estimates for natural-origin and hatchery-origin steelhead within the Wenatchee River, brood years 2014-2016. Escapement estimates were based on PIT-tag mark-recapture techniques (see Appendix D).

## Straying

Stray rates of Wenatchee steelhead can be estimated by examining the locations where PIT-tagged hatchery steelhead were last detected. PIT tagging of steelhead began with brood year 2005, which allows estimation of stray rates by brood return. These data only provide estimates for brood years 2005 through 2012, because later brood years are still rearing in the ocean. The most recent completed brood year is 2012.

Based on PIT-tag analyses, about 5.1\% of brood year 2012 was last detected in streams outside of the Wenatchee River basin. Beginning with brood year 2011, steelhead have been overwinteracclimated at the Chiwawa Acclimation Facility. This may be the reason for the observed reduction in stray rates since 2011. On average, for brood years 2011 through 2012, about $4 \%$ of the hatchery steelhead returns were last detected in streams outside the Wenatchee River basin (Table 3.25).

Steelhead have been detected in the Entiat and Methow rivers as well as in the Deschutes and Tucannon rivers. Several were last detected at Wells Dam. The numbers in Table 3.25 should be considered rough estimates because they are not based on confirmed spawning (only last detections).
Table 3.25. Number and percent of hatchery-origin Wenatchee steelhead that homed to target spawning areas and the target hatchery program, and number and percent that strayed to non-target spawning areas and hatchery programs for brood years 2005-2012. Estimates were based on last detections of PIT-tagged hatchery steelhead. Percent strays should be less than 5\%.

* Homing to the target hatchery includes Wenatchee hatchery steelhead that are captured and included as broodstock in the Wenatchee Hatchery program. These hatchery fish are typically collected at Dryden and Tumwater dams.

## Genetics

Genetic studies were conducted in 2012 to determine the potential effects of the Wenatchee Supplementation Program on natural-origin summer steelhead in the Wenatchee River basin (Seamons et al. 2012; the entire report is appended as Appendix E). Temporal collections were obtained from hatchery and natural-origin adult summer steelhead captured at Dryden and Tumwater dams during summer and fall of 1997 through 2009 (excepting 2004 and 2005). Naturalorigin steelhead consisted of a mixed collection representing all the spawning subpopulations located upstream. Therefore, to determine population substructure within the basin, samples were also taken from juvenile steelhead collected at smolt traps located within the Chiwawa River, Nason Creek, and Peshastin Creek, and from the Entiat River. Samples were also taken from juvenile steelhead collected at the smolt trap in the lower Wenatchee River. These, like naturalorigin adult collections, consisted of a mixed collection representing all subpopulations located upstream. A total of 1,468 hatchery-origin and natural-origin adults were processed and 1,542 juvenile steelhead from the Wenatchee and Entiat Rivers were processed for genetic variation with 132 genetic (single nucleotide polymorphism loci; SNPs) markers. Peshastin Creek and the Entiat River served as no-hatchery-outplant controls. Genetic data were interrogated for the presence or absence of spatial and temporal trends in allele frequencies, genetic distances, and effective population size.

Allele Frequencies-Changes to the summer steelhead hatchery supplementation program had no detectable effect on genetic diversity of wild populations. On average, hatchery-origin adults had higher minor allele frequencies (MAF) than natural-origin adults, which may simply reflect the mixed ancestry of hatchery adults. Both hatchery and natural-origin adults had MAF similar to juveniles collected in spawning tributaries and in the Entiat River. There was no temporal trend in allele frequencies or observed heterozygosity in adult or juvenile collections and allele frequencies in control populations were no different than those still receiving hatchery outplants. This suggests that the hatchery program has had little effect on allele frequencies since broodstock sources changed in 1998 from mixed-ancestry broodstock collected in the Columbia River to using broodstock collected in the Wenatchee River.

Genetic Distances-As intended, interbreeding of Wenatchee River hatchery and natural-origin adults reduced the genetic differences between Wells Hatchery adults and Wenatchee River natural-origin adults observed in the first few years after changing the broodstock collection protocol. Although there were detectable genetic differences between hatchery and natural-origin adults, the magnitude of that difference declined over time. Hatchery adults were genetically different from natural-origin adults and juveniles based on pair-wise $F_{\text {ST }}$ and principal components analysis, most likely because of the smaller effective population size $\left(N_{\mathrm{b}}\right)$ in the hatchery population (see below). Pair-wise $F_{\text {ST }}$ estimates and genetic distances between hatchery and natural-origin adults collected the same year declined over time suggesting that the interbreeding of hatchery and natural-origin adults in the hatchery (and presumably in the wild) is slowly homogenizing Wenatchee River summer steelhead. Analyses using brood year were inconclusive because of limitations in the data.

Effective Population Size-Although the effective population size of the Wenatchee River hatchery steelhead program was consistently small, it does not appear to have caused a reduction in the effective population size of wild populations. On average, estimates of $N_{\mathrm{b}}$ were much lower and varied less for hatchery adults than for natural-origin adults and juveniles. Estimates of $N_{\mathrm{b}}$ for hatchery adults declined from the earliest brood years to a stable new low value after broodstock practices were changed in 1998. There was no indication that this had any effect on $N_{\mathrm{b}}$ in naturalorigin adults and juveniles; $N_{\mathrm{b}}$ estimates for natural-origin adults and juveniles were, on average, higher and varied considerably over the 1998-2010 period and showed no temporal trend.

It is important to note that no new information will be reported on genetics until the next five-year report (2018).

## Proportionate Natural Influence

Another method for assessing the genetic risk of a supplementation program is to determine the influence of the hatchery and natural environments on the adaptation of the composite population. This is estimated by the proportion of natural-origin fish in the hatchery broodstock ( pNOB ) and the proportion of hatchery-origin fish in the natural spawning escapement (pHOS). We calculated Proportionate Natural Influence (PNI) by iterating Ford's (2002) equations 5 and 6 to equilibrium, using a heritability of 0.3 and a selection strength of three standard deviations. ${ }^{7}$ The larger the PNI value, the greater the strength of selection in the natural environment relative to that of the hatchery

[^4]environment. For the natural environment to dominate selection, PNI should be greater than 0.50 , and important integrated populations should have a PNI of at least 0.67 (HSRG/WDFW/NWIFC 2004). For the Wenatchee steelhead program, PNI is managed with the goal of achieving a fiveyear running average of $\mathrm{PNI} \geq 0.67$ basin-wide. In years when the natural-origin escapement is low (i.e., < 433 fish), the Wenatchee steelhead population will be managed to meet escapement goals rather than PNI.

For brood years 2001-2016, PNI values were less than 0.67 (Table 3.26), suggesting that the hatchery environment has a greater influence on adaptation of Wenatchee steelhead than does the natural environment.

Table 3.26. Proportionate Natural Influence (PNI) values for the Wenatchee steelhead supplementation program for brood years 2001-2016. NOS = number of natural-origin steelhead on the spawning grounds; HOS = number of hatchery-origin steelhead on the spawning grounds; NOB = number of natural-origin steelhead collected for broodstock; and HOB = number of hatchery-origin steelhead included in hatchery broodstock.

${ }^{\text {a }}$ The presence of eroded fins or missing adipose fins was used to distinguish hatchery fish from wild fish during video monitoring at Tumwater The PNI estimates are appropriate for steelhead spawning upstream from Tumwater Dam but may not represent PNI for steelhead spawning downstream from Tumwater Dam. Dam. Because not all hatchery fish have eroded fins or missing adipose fins, it is likely we are underestimating WxW hatchery steelhead returns based on video monitoring.
${ }^{\mathrm{b}}$ PNI was calculated previously using PNI approximate equation 11 (HSRG 2009; their Appendix A). All PNI values presented here were recalculated by iterating Ford's (2002) equations 5 and 6 to equilibrium using a heritability of 0.3 and a selection strength of three standard deviations. C. Busack, NOAA Fisheries, 21 March 2016, provided the model for calculating PNI.

## Post-Release Survival and Travel Time

We used PIT-tagged fish to estimate survival rates and travel time (arithmetic mean days) of hatchery steelhead from release sites (e.g., Chiwawa River, Nason Creek, and Wenatchee River) to McNary Dam, and smolt to adult ratios (SARs) from release to detection at Bonneville Dam (Table 3.27). ${ }^{8}$ Over the 12 brood years for which PIT-tagged hatchery fish are available, survival rates from the release sites to McNary Dam ranged from 0.055 to 0.785 (note that survival rates of 0.000 were associated with very small sample sizes); SARs from release to detection at Bonneville Dam ranged from 0.000 to 0.038 . Average travel time from the release sites to McNary Dam ranged from 13 to 100 days.

Some of the variation in survival rates and travel time was related to release location, type of release, and rearing scenario. For example, on average, steelhead released in the Chiwawa River appeared to have higher survival rates to McNary Dam than did steelhead released in the lower and upper Wenatchee River or Nason Creek. Within the Chiwawa River, steelhead identified as "movers" had the highest survival rates to McNary Dam, while those identified as "non-screened" had the lowest survival. For steelhead released into Nason Creek and the Wenatchee River, fish released from circulars had higher survival rates than those released from raceways. On average, steelhead released from Blackbird Pond had lower survival rates to McNary Dam than those released from circulars. Based on the available data, SARs varied little among the release locations or rearing scenarios.

Travel time from release to McNary Dam varied among release locations and rearing scenario. In general, steelhead released into the Chiwawa River and Nason Creek appeared to travel more quickly to McNary Dam than did steelhead released into the Wenatchee River. Of those released into the Chiwawa River, steelhead released volitionally from raceways appeared to travel to McNary Dam more quickly than those forced released; although there are few replicates and differences in travel times are small. On average, there appeared to be little differences in travel times for steelhead reared in raceways or circulars that were released into Nason Creek.
Table 3.27. Total number of Wenatchee hatchery summer steelhead released with PIT tags, their survival and travel times (mean days) to McNary Dam, and smolt-to-adult (SAR) ratios for brood years 2005-2015. SARs were estimated to Bonneville Dam. Standard errors are shown in parentheses. NA = not available (i.e., for SARs, not all the adults from the release groups have returned to the Columbia River).

## Natural and Hatchery Replacement Rates

Natural replacement rates (NRR) were calculated as the ratio of natural-origin recruits (NOR) to the parent spawning population (spawning escapement). Natural-origin recruits are naturally produced (wild) fish that survive to contribute to harvest (directly or indirectly), to broodstock, and to spawning grounds. We do not account for fish that died in route to the spawning grounds (migration mortality) or died just before spawning (pre-spawn mortality) (see Appendix B in Hillman et al. 2012). For brood years 1998-2012, NRR for summer steelhead in the Wenatchee River basin averaged 0.66 (range, $0.13-3.10$ ) if harvested fish were included in the estimate (Table 3.28).

Hatchery replacement rates (HRR) are the hatchery adult-to-adult returns and were calculated as the ratio of hatchery-origin recruits (HOR) to the parent broodstock collected. These rates should be greater than the NRRs and greater than or equal to 6.9 (the calculated target value in Hillman et al. 2013). The target value of 6.9 includes harvest. In nearly all years, HRRs were greater than NRRs (Table 3.28). HRRs exceeded the estimated target value of 6.9 in 11 of the 15 years.

Table 3.28. Broodstock collected, spawning escapements, natural and hatchery-origin recruits (NOR and HOR), and natural and hatchery replacement rates (NRR and HRR with harvest) for summer steelhead in the Wenatchee River basin, brood years 1998-2012.

## Smolt-to-Adult Survivals

Smolt-to-adult ratios (SARs) are calculated as the number of returning hatchery adults divided by the number of tagged hatchery smolts released. SARs are generally based on CWT returns. However, prior to brood year 2011, Wenatchee steelhead were not extensively tagged with CWTs. Therefore, elastomer-tagged fish were used to estimate SARs from release to capture at Priest Rapids Dam. With the return of brood year 2011, SARs will be based on PIT-tag detections at Bonneville Dam.

SARs (not adjusted for tag loss) for Wenatchee steelhead ranged from 0.0009 to 0.0315 (mean $=$ 0.0093 ) for brood years 1996-2010 (Table 3.29). For brood years 2011 to present, SARs (to Bonneville Dam) averaged 0.0056 (Table 3.29).

Table 3.29. Smolt-to-adult ratios (SARs) for Wenatchee hatchery steelhead. Estimates for brood years 1996-2010 were based on elastomer tags recaptured at Priest Rapids Dam. SARs were not adjusted for tag loss after release. For brood years 2011 to present, SARs are based on PIT-tag detections to Bonneville Dam.

| Brood year | Number of tagged smolts released | SAR |

${ }^{\text {a }}$ Only $192,363 \mathrm{WxW}$ progeny from brood year 2010 were elastomer tagged; $161,951 \mathrm{HxH}$ steelhead were released.

### 3.7 ESA/HCP Compliance

## Broodstock Collection

Collection of brood year 2015 broodstock for Wenatchee summer steelhead at Dryden and Tumwater dams began on 1 July and ended on 15 October 2014 at Dryden Dam and 10 November 2014 at Tumwater Dam consistent with the collection period identified in the 2014 broodstock collection protocol. The broodstock collection achieved a total collection of 142 steelhead, including 76 natural-origin steelhead (of the 76 fish collected, 58 were spawned and 13 were released back to the river.

About 1,278 steelhead were handled and released (or surplused) at Tumwater and Dryden dams during brood year 2015 Wenatchee steelhead broodstock collection. Most were hatchery-origin fish handled at Tumwater Dam and ultimately surplused to meet the pHOS objective upstream from Tumwater Dam. Fish released at Dryden Dam were released because the weekly quota for hatchery or wild steelhead had been attained, but not for both hatchery and wild fish, or because they were non-target fish (adipose clipped), or they were unidentifiable hatchery-origin steelhead. All steelhead released were allowed to fully recover from the anesthesia and released immediately upstream from the trap sites.

In addition to steelhead encountered at Dryden Dam during steelhead broodstock collection, an estimated 48 spring Chinook salmon were captured and released unharmed immediately upstream
from the trap facility. Consistent with ESA Section 10 Permit 1395 impact minimization measures, all ESA species handled were subject of water-to-water transfers.

## Hatchery Rearing and Release

The 2015 brood Wenatchee steelhead reared throughout all life stages without significant mortality (defined as $>10 \%$ population mortality associated with a single event). However, the 2015 brood had poor fertilization to eyed-egg survival ( $60.3 \%$ ) combined with somewhat low eyed-egg to ponding survival resulting in an unfertilized-to-release survival of $68.5 \%$, which was considerably less than the program target of $81 \%$ (see Section 3.2).

Juvenile rearing occurred at three separate facilities including Eastbank Fish Hatchery, Chelan Fish Hatchery, and the Chiwawa Acclimation Facility. Multiple facilities were used to take advantage of variable water temperatures to manipulate growth of juveniles from different parental crosses. Typically, wild steelhead spawn later than their hatchery cohort and are therefore reared at Chelan Fish Hatchery on warmer water to accelerate their growth so they achieve a size-atrelease similar to HxH parental cross progeny reared on cooler water at Eastbank Fish Hatchery. All parental cross groups received final rearing and over-winter acclimation at the Chiwawa Acclimation Facility on Wenatchee River and Chiwawa River surface water before direct release (scatter planting) in the Wenatchee River basin.
The 2015 brood steelhead smolt release in the Wenatchee River basin totaled 195,344 smolts, representing about $79 \%$ of the program target of 247,300 smolts identified in the Rocky Reach and Rock Island Dam HCPs and within the maximum $110 \%$ allowed in ESA Section 10 Permit 1395. As specified in ESA Section 10 Permit 1395, all steelhead smolts released were externally marked or internally tagged and a representative number were PIT tagged (see Section 3.2).

## Hatchery Effluent Monitoring

Per ESA Permits 1196, 1347, 1395, 18118, 18120, and 18121, permit holders shall monitor and report hatchery effluents in compliance with applicable National Pollution Discharge Elimination Systems (NPDES) (EPA 1999) permit limitations. There was no NPDES violations reported at PUD Hatchery facilities during the period 1 January 2016 through 31 December 2016. NPDES monitoring and reporting for Chelan PUD Hatchery Programs during 2016 are provided in Appendix F.

## Smolt and Emigrant Trapping

Per ESA Section 10 Permit No. 1395, the permit holders are authorized a direct take of up to $20 \%$ of the emigrating steelhead population and a lethal take not to exceed $2 \%$ of the fish captured (NMFS 2003). Based on the estimated wild steelhead population (smolt trap expansion) and hatchery juvenile steelhead population estimate (hatchery release data) for the Wenatchee River basin, the reported steelhead encounters during the 2016 emigration complied with take provisions in the Section 10 permit and are detailed in Table 3.30. Additionally, juvenile fish captured at the trap locations were handled consistent with provisions in ESA Section 10 Permit 1395 Section B.

${ }^{\mathrm{b}}$ Mortality includes trapping and PIT-tag mortalities.

## Spawning Surveys

Steelhead spawning ground surveys were conducted in the Wenatchee River basin during 2016, as authorized by ESA Section 10 Permit No. 1395. Because of the difficulty of quantifying the level of take associated with spawning ground surveys, the Permit does not specify a take level associated with these activities, even though it does authorize implementation of spawning ground surveys. Therefore, no take levels are reported. However, to minimize potential effects to established redds, wading was restricted to the extent practical, and extreme caution was used to avoid established redds when wading was required.

## Stock Assessment at Priest Rapids Dam

Upper Columbia River steelhead stock assessment sampling at Priest Rapids Dam (PRD) is authorized through ESA Section 10 Permit No. 1395 (NMFS 2003). Permit authorizations include interception and biological sampling of up to $15 \%$ of the Upper Columbia River steelhead passing PRD to determine upriver adult population size, estimate hatchery to wild ratios, determine ageclass contribution, and evaluate the need for managing hatchery steelhead consistent with ESA recovery objectives, which include fully seeding spawning habitat with naturally produced Upper Columbia River steelhead supplemented with artificially propagated steelhead (NMFS 2003). The 2014-2015 run-cycle report (BY 2015) for stock assessment sampling at Priest Rapids Dam was compiled under provisions of ESA Section 10 Permit 1395. Data and reporting information are included in Appendix G.

## SECTION 4: WENATCHEE SOCKEYE SALMON

The goal of sockeye salmon supplementation in the Wenatchee Basin was to use artificial production to replace adult production lost because of mortality at Rock Island Dam, while not reducing the natural production or long-term fitness of sockeye in the basin. The Rock Island Fish Hatchery Complex began operation in 1989 under funding from Chelan PUD. The Complex operated originally through the Rock Island Settlement Agreement, but since 2004 has operated under the Anadromous Fish Agreement and Habitat Conservation Plans.

Adult sockeye were collected for broodstock from the run-at-large at Tumwater Dam. Beginning in 2011, because of passage delays at Tumwater Dam during trapping operations, sockeye broodstock were collected at Dryden Dam. The goal was to collect up to 260 natural-origin adult sockeye for the program. Broodstock collection occurred from about 7 July through 28 August with trapping occurring no more than 16 hours per day, three days a week at Tumwater Dam and up to seven days per week at the Dryden Dam left and right-bank facilities.

Adult sockeye were held and spawned at Eastbank Fish Hatchery. The fertilized eggs were also incubated at the hatchery. For brood years 1989 through 1998, unfed fry were transferred from the hatchery to Lake Wenatchee net pens. From 1998 to 2011, juvenile sockeye were reared at Eastbank Fish Hatchery until July when they were transferred to the net pens. The initial rearing at Eastbank was to increase growth rates. During most years up through 2005, juvenile sockeye were released from net pens at two different times, August and November. Since 2006, all juvenile sockeye were released in late October.

The production goal for the Wenatchee sockeye supplementation program was to release 200,000 subyearlings into Lake Wenatchee at 20 fish per pound. Targets for fork length and weight were $133 \mathrm{~mm}(\mathrm{CV}=9.0)$ and 22.7 g , respectively. Over $90 \%$ of these fish were marked with CWTs. In addition, from 2006-2011, about 15,000 juvenile sockeye were PIT tagged annually. Following an evaluation of the supplementation program in 2011, the Hatchery Committees decided to convert the Wenatchee sockeye hatchery program to summer steelhead in 2012. Monitoring occurs annually to track the status of the natural sockeye population.

### 4.1 Broodstock Sampling

As noted above, the Wenatchee sockeye program was terminated in 2012. Thus, no broodstock have been collected since 2011 and the release of juvenile sockeye into Lake Wenatchee in 2012 (2011 brood) was the last. Therefore, this section presents the history of the program and tracks the juveniles from the 2011 brood that were released as parr into Lake Wenatchee in 2012. Some of these fish began their smolt migrations in 2013.

## Origin of Broodstock

Wenatchee sockeye broodstock have not been collected since 2011. Table 4.1 shows the history of the number of broodstock that were collected during the period 1989 to 2011.

Table 4.1. Numbers of wild and hatchery sockeye salmon collected for broodstock, numbers that died before spawning, and numbers of sockeye spawned, 1989-2011. Unknown origin fish (i.e., undetermined by scale analysis, no CWT or fin clips, and no additional hatchery marks) were considered naturally produced. Mortality includes sockeye that died of natural causes typically near the end of spawning and were not needed for the program, surplus sockeye killed at spawning, sockeye that died but were not recovered from the net pens, and sockeye that may have jumped out of the net pens.

| Brood year | Wild sockeye |  |  |  |  | Hatchery sockeye |  |  |  |  | Total number spawned |

## Fecundity

Fecundities of sockeye collected during the life of the hatchery program are presented in Table 4.5.

Table 4.5. Mean fecundity of female sockeye salmon collected for broodstock, 1989-2011. Fecundities were determined from pooled egg lots and were not identified for individual females.

| Return year | Mean fecundity |

### 4.3 Disease Monitoring

Because the sockeye hatchery program was terminated in 2012, there are no disease-monitoring results.

### 4.4 Natural Juvenile Productivity

Sockeye smolt abundance was estimated at a rotary screw trap located near the mouth of Lake Wenatchee during the period 1997 to 2011. Because the efficiency of the trap was difficult to assess, the operation was terminated in 2011. In 2012, the trap was relocated downstream near the mouth of the Chiwawa River and operated there for two years. Again, because few marked sockeye smolts were recaptured, the operation was terminated in 2013. Beginning in 2013, smolt abundance has been estimated at the Lower Wenatchee Trap.

## Emigrant and Smolt Estimates

The Lower Wenatchee Trap operated between 29 January and 26 July 2016. During that time, the trap was inoperable for 23 days because of high and low river discharge, debris, elevated river temperature, large hatchery releases, and mechanical issues. During the sampling period, a total of 1,346 wild juvenile sockeye were captured at the Lower Wenatchee Trap. A significant relationship between trap efficiency and river discharge was created ( $\mathrm{R}^{2}=0.52, P<0.043$ ). Using this model, the number of juvenile sockeye emigrants was estimated at 208,250 ( $\pm 29,447 ; 95 \%$ CI) during the 2016 trapping season (Table 4.11). Because of high flows coupled with mechanical issues, the trap was not fully operational during peak sockeye emigration. For this reason, the population estimate is considered a minimum. Figure 4.1 shows the monthly captures of sockeye collected at the Lower Wenatchee Trap in 2016. All fish captured in the Lower Wenatchee trap are reported in Appendix B.

Table 4.11. Estimated numbers of wild and hatchery sockeye smolts that emigrated from Lake Wenatchee during run years 1997-2016; NS = no data. Estimates for the run years 1997-2011 were based on sampling at the Upper Wenatchee smolt trap; estimates beginning in 2013 were based on sampling at the Lower Wenatchee smolt trap.

| Run year | Numbers of sockeye smolts |  |

${ }^{\text {a }}$ Estimates refined based on PIT tag survival to McNary Dam.
${ }^{\mathrm{b}}$ Summary statistics were calculated for years in which hatchery fish were being released (1997-2011).

## Juvenile Sockeye

Figure 4.1. Monthly captures of wild sockeye salmon smolts at the Lower Wenatchee Trap, 2016.

Age classes of wild sockeye smolts were determined from a length frequency analysis based on scales collected randomly each year since 1997 (Table 4.12). Each year, a small number of markedly smaller sockeye ( $<50 \mathrm{~mm}$ FL) are collected, and starting with run year 2013, an age-0 class was retroactively assigned based on catch records. For the available run years, most wild sockeye smolts migrated as age $1+$ fish. Only in two years (1997 and 2005) did more smolts migrate as age $2+$ fish. Relatively few smolts migrated at age $3+$.
Table 4.12. Age structure and estimated number of wild sockeye smolts that emigrated from Lake Wenatchee, 1997-2016; ND = no data. Estimates for the run years 1997-2011 were based on sampling at the Upper Wenatchee smolt trap; estimates beginning in 2013 were based on sampling at the Lower Wenatchee smolt trap.

| Run year | Proportion of wild smolts |  |  |  | Total wild emigrants |

## Freshwater Productivity

Egg-smolt survival estimates for wild sockeye salmon are provided in Table 4.13. Estimates of egg deposition were calculated based on the spawner escapement at Tumwater Dam and the sex ratio and fecundity of the broodstock. For the 2012 brood year (a year where brood was not collected), a linear relationship with post-orbital to hypural length as the independent variable was used to calculate average fecundity of sockeye sampled at Tumwater Dam ( $\mathrm{r}^{2}=0.40, \mathrm{P}<0.01$ ). Smolts for brood years 1995-2009 were based on captures at the Upper Wenatchee Trap. No smolt
estimates are available for brood year 2010. Smolt estimates for brood years since 2012 are derived from captures made at the Lower Wenatchee Trap. Egg-smolt survival rates for brood years 19952014 have ranged from 0.012 to 0.212 ( mean $=0.084$ ).
Table 4.13. Estimated egg deposition (estimated as mean fecundity times estimated number of females), numbers of smolts, and survival rates for wild Wenatchee sockeye salmon, brood years 1995-2014; NA = not available.

${ }^{\mathrm{a}}$ There is no emigrant estimate for trapping during 2012.
${ }^{\mathrm{b}}$ Emigrant estimates are derived from captures at the Lower Wenatchee Trap.

Juvenile survival rates for hatchery sockeye salmon are provided in Table 4.14. Release-smolt survival rates for brood years 1995-2009 have ranged from 0.000 to 1.000 (mean $=0.570$ ). Eggsmolt survival rates for the same brood years ranged from 0.000 to 0.710 (mean $=0.294$ ). On average, egg-smolt survival of hatchery sockeye is about three times greater than egg-smolt survival of wild sockeye.

Table 4.14. Juvenile survival rates for hatchery Wenatchee sockeye, brood years 1995-2009.

| Brood year | Number of eggs | Number of parr released | Date of release | Estimated number of smolts | Egg-smolt survival | Release-smolt survival |

## PIT Tagging Activities

A total of 1,065 wild juvenile sockeye salmon were PIT tagged and released in 2016 at the Lower Wenatchee Trap. Numbers of wild sockeye salmon PIT-tagged and released as part of the Comparative Survival Study and PUD studies during the period 2006-2016 are shown in Table 4.15. See Appendix C for a complete list of all fish captured, tagged, lost, and released.

Table 4.15. Summary of the numbers of wild sockeye salmon that were tagged and released at the Upper and Lower Wenatchee Traps within the Wenatchee River basin, 2006-2016.

| Sampling Location | Numbers of PIT-tagged sockeye salmon released |  |  |  |  |  |  |  |  |

### 4.5 Spawning Escapement

The sockeye salmon hatchery program ended after the 2011 brood year. As a result, monitoring activities that focused on evaluating the effects of the supplementation program on the natural population switched to monitoring the abundance and productivity of the natural population. Broadly, the proposed monitoring and evaluation activities cover juvenile and adult life-history stages and provide the data necessary to track or estimate viable salmonid population parameters (VSP); abundance, productivity, spatial structure, and diversity (McElhaney et al. 2000).

From 2009-2013, mark-recapture methods were used to estimate spawning escapement within the White River, while area-under-the-curve (AUC) methods were used to estimate spawning escapement within the Little Wenatchee River. Beginning in 2014, mark-recapture methods were used to estimate the spawning escapement of sockeye in the White River and Little Wenatchee watersheds (see Appendix H for more details).

## Mark-Recapture Estimates

Spawning escapement of sockeye salmon in 2016 was estimated using mark-recapture methods. This method relied on PIT tags to estimate sockeye spawning escapement (see Appendix H for more details).
Using mark-recapture methods, the estimated total escapement of sockeye in the Upper Wenatchee River basin in 2016 was 45,068 (Table 4.16). About $85 \%$ of the escapement entered the White River watershed (including the Napeequa River).

Table 4.16. Estimated escapement of adult sockeye into the Little Wenatchee and White River watersheds for return years 2009-2016. Escapement was based on recapture of PIT-tagged fish.

| Return year | Tumwater Dam count | Recreational harvest | Little Wenatchee escapement | White River escapement | Total spawning escapement |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 2009 | 16,034 | 2,285 | 576 | 13,876 | 14,452 |
| 2010 | 35,821 | 4,129 | 2,062 | 19,542 | 21,604 |
| $2011^{\text {a }}$ | 18,634 | 0 | 2,431 | 14,582 | 17,013 |
| 2012 | 66,520 | 12,107 | 4,607 | 23,866 | 28,473 |
| $2013{ }^{\text {a }}$ | 29,015 | 6,262 | 2,426 | 14,294 | 16,720 |
| 2014 | 99,898 | 16,281 | 4,319 | 49,021 | 53,340 |
| 2015 | 51,435 | 7,916 | 4,115 | 20,097 | 24,212 |
| 2016 | 73,697 | 14,630 | 6,747 | 38,321 | 45,068 |
| Average | 48,882 | 7,951 | 3,234 | 24,200 | 27,434 |
| Median | 43,628 | 7,089 | 2,569 | 19,820 | 22,204 |

${ }^{\text {a }}$ Spawning escapements in 2011 and 2013 were calculated using AUC counts and a regression model.
The spawning escapement of 45,068 Wenatchee sockeye was greater than the overall average of 27,434 (Table 4.17).

Table 4.17. Spawning escapements for sockeye salmon in the Wenatchee River basin for return years 19892016; NA = not available and AUC = area under the curve.

### 4.6 Carcass Surveys

As described earlier, carcass surveys were not conducted in 2016. The information contained in this section represents carcass data collected before 2014.

## Number sampled

Table 4.18 shows the number of carcasses sampled within different survey streams during the period 1993-2013.
Table 4.18. Numbers of sockeye carcasses sampled within different streams/watersheds within the Wenatchee River basin, 1989-2013.

| Survey year | Numbers of sockeye carcasses |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
|  | Little Wenatchee | White | Napeequa | Total |
| 1993 | 90 | 195 | 0 | 285 |
| 1994 | 121 | 165 | 0 | 286 |
| 1995 | 0 | 56 | 0 | 56 |
| 1996 | 43 | 1,387 | 3 | 1,433 |
| 1997 | 69 | 1,425 | 41 | 1,535 |

| 2011 | 372 | 3,322 | 48 | 3,742 |
| 2012 | 1,309 | 7,479 | 31 | 8,819 |
| 2013 | 179 | 2,996 | 27 | 3,202 |
| Average | 279 | 2,865 | 33 | 3,178 |
| Median | 101 | 2,158 | 14 | 2,297 |

## Carcass Distribution and Origin

Based on the available data (1993-2013), the largest percentage of both wild and hatchery sockeye spawned in Reach 2 on the White River (Table 4.19 and Figure 4.2). However, a greater percentage of wild fish was found in Reach 2 than hatchery fish.

Table 4.19. Numbers of wild and hatchery sockeye carcasses sampled within different reaches in the Wenatchee River basin, 1993-2013. Reach codes are described in Table 2.9.

| Survey year | Origin | Numbers of sockeye carcasses |  |  |  |  |  |

## Wenatchee Sockeye Salmon

Figure 4.2. Distribution of wild and hatchery produced carcasses in different reaches in the Wenatchee River basin, pooled data from 1993-2013. Reach codes are described in Table 2.9; L = Little Wenatchee, $\mathrm{H}=$ White River, and $\mathrm{Q}=$ Napeequa River.

### 4.7 Life History Monitoring

Life history characteristics of Wenatchee sockeye were assessed by examining carcasses on spawning grounds and fish sampled at broodstock collection sites or during stock assessment, and by reviewing tagging data and fisheries statistics.

## Migration Timing

There was little difference in migration timing of hatchery and wild sockeye past Tumwater Dam (Table 4.20a and b; Figure 4.3). On average, early in the run, hatchery and wild sockeye arrived at the dam at about the same time. Toward the end of the migration period, hatchery sockeye tended
to arrive at the dam slightly later than did wild sockeye. Most hatchery and wild sockeye migrated upstream past Tumwater Dam during July through early August. The peak migration time for both hatchery and wild sockeye was the last two weeks of July (Figure 4.3).
Table 4.20a. The Julian day and date that $10 \%, 50 \%$ (median), and $90 \%$ of the wild and hatchery sockeye salmon passed Tumwater Dam, 1998-2016. The average Julian day and date are also provided. Migration timing is based on video sampling at Tumwater. Data for 1998 through 2003 were based on videotapes and broodstock trapping and may not reflect the actual number of hatchery sockeye salmon. All sockeye were visually examined during trapping from 2004 to present.

| Survey year | Origin | Sockeye Migration Time (days) |  |  |  |  |  |  |  | $\begin{gathered} \text { Sample } \\ \text { size } \end{gathered}$ |

${ }^{\text {a }}$ The origin of sockeye passing Tumwater Dam during 8 through 11 August 2012 was not assessed. The total number of sockeye passing Tumwater Dam in 2012 was 30,617 adults. Thus, about 9,023 adults of unknown origin passed Tumwater Dam in 2012.

Table 4.20b. The week that $10 \%, 50 \%$ (median), and $90 \%$ of the wild and hatchery sockeye salmon passed Tumwater Dam, 1998-2016. The average week is also provided. Migration timing is based on video sampling at Tumwater. Data for 1998 through 2003 were based on videotapes and broodstock trapping and may not reflect the actual number of hatchery sockeye salmon. All sockeye were visually examined during trapping from 2004 to present.

${ }^{\text {a }}$ The origin of sockeye passing Tumwater Dam during 8 through 11 August 2012 was not assessed. The total number of sockeye passing Tumwater Dam in 2012 was 30,617 adults. Thus, about 9,023 adults of unknown origin passed Tumwater Dam in 2012.

## Sockeye Migration Timing

Figure 4.3. Proportion of wild and hatchery sockeye observed (using video) passing Tumwater Dam each week during their migration period late-June through early-October; data were pooled over survey years 1998-2016.

## Age at Maturity

Although sample sizes are small, most hatchery sockeye returned as age-4 fish, while most wild sockeye returned as age-4 and 5 fish (Table 4.21; Figure 4.4). Only wild fish have returned at age6.

Table 4.21. Proportions of wild and hatchery sockeye of different ages (total age) sampled in broodstock (1994-2011), on spawning grounds (1994-2012), and at Tumwater Dam (2013-2016).

Sockeye Age Structure

Figure 4.4. Proportions of wild and hatchery sockeye salmon of different total ages sampled at Tumwater Dam and on spawning grounds in the Wenatchee River basin for the combined years 1994-2016.

## Size at Maturity

Although sample sizes are small, wild and hatchery sockeye differed in mean length in 2016 (Table 4.22). However, the pooled data indicate that there is little difference in mean sizes of hatchery and wild sockeye salmon sampled in the Wenatchee River basin (Table 4.22). Analyses for the five-year reports will compare sizes of hatchery and wild fish of the same age groups and sex.

Table 4.22. Mean lengths ( $\mathrm{POH} ; \mathrm{cm}$ ) and variability statistics for wild and hatchery sockeye salmon sampled at Dryden Dam (broodstock) and on spawning grounds in the Wenatchee River basin, 1994-2016; SD $=1$ standard deviation. From 2014 to present, data are collected from sockeye sampled at Tumwater Dam.

| Survey year | Origin | Sample size | Sockeye length (POH; cm) |  |  |  |

## Contribution to Fisheries

The total number of hatchery and wild sockeye captured in different fisheries is provided in Tables 4.23 and 4.24. Harvest on hatchery-origin sockeye has been less than the harvest on wild sockeye.

Table 4.23. Estimated number and percent (in parentheses) of hatchery-origin Wenatchee sockeye captured in different fisheries, brood years 1989-2010.

| Brood year | Ocean fisheries | Columbia River Fisheries |  |  | Total |

${ }^{a}$ Includes the Lake Wenatchee fishery.

## Straying

Stray rates were determined by examining CWTs recovered on spawning grounds within and outside the Wenatchee River basin. In addition, PIT tagging of hatchery sockeye, which began with brood year 2005, allows estimation of stray rates by brood return. Targets for strays based on return year (recovery year) outside the Wenatchee River basin should be less than 5\%. The target for brood year strays should also be less than $5 \%$.
Based on CWTs and brood year analysis, virtually no hatchery-origin Wenatchee sockeye strayed into non-target spawning areas or hatchery programs before brood year 2006 (Table 4.25). However, sockeye from brood years 2006 and 2007 strayed into the Entiat River and a few into the Methow River (non-target streams) and a non-target hatchery (Umpqua Trap) (Table 4.25).

Stray rates of Wenatchee sockeye from brood year 2006-2010 exceeded the target of 5\%. The number of returning hatchery sockeye has decreased since brood year 2008.

Table 4.25. Number and percent of hatchery-origin Wenatchee sockeye that homed to target spawning areas and the target hatchery program, and number and percent that strayed to non-target spawning areas and hatchery programs, by brood years 1990-2010. Hatchery-origin sockeye from brood years 1995-1998 were not tagged because of columnaris disease ( $\mathrm{NA}=$ not available). Percent stays should be less than $5 \%$.

* Homing to the target hatchery includes Wenatchee hatchery sockeye that are captured and included as broodstock in the Wenatchee Hatchery program. These hatchery fish were collected at Tumwater Dam.

Based on PIT-tag analyses, on average, about $11 \%$ of the hatchery sockeye returns were last detected in streams outside the Wenatchee River basin (Table 4.26). The numbers in Table 4.26 should be considered rough estimates because they are not based on confirmed spawning (only last detections). Nevertheless, these data do indicate that some hatchery sockeye from the Wenatchee program have strayed into the Entiat and Methow rivers and possibly into the Okanogan system (based on sockeye detected at Wells Dam but not in the Methow River).

Table 4.26. Number and percent of hatchery-origin Wenatchee sockeye that homed to target spawning areas and the target hatchery program, and number and percent that strayed to non-target spawning areas and hatchery programs for brood years 2005-2011. Estimates were based on last detections of PIT-tagged hatchery sockeye. Percent strays should be less than 5\%.

## Genetics

Genetic studies were conducted in 2008 to determine the potential effects of the Wenatchee sockeye supplementation program on natural-origin sockeye in the upper Wenatchee River basin (Blankenship et al. 2008; the entire report is appended as Appendix I). Specifically, the objective of the study was to determine if the genetic composition of the Lake Wenatchee sockeye population had been altered by the supplementation program, which was based on the artificial propagation of a small subset of the Wenatchee population. Microsatellite DNA allele frequencies were used to differentiate between temporally replicated collections of natural and hatchery-origin sockeye in the Wenatchee River basin. A total of 13 collections of Wenatchee sockeye were analyzed; eight temporally replicated collections of natural-origin sockeye ( $\mathrm{N}=786$ ) and five temporally replicated collections of hatchery-origin sockeye ( $\mathrm{N}=248$ ). Paired natural-hatchery collections were available from return years 2000, 2001, 2004, 2006, and 2007. All collections were taken at Tumwater Dam and consisted of dried scales and fin clips.

Overall, the study showed that allele frequency distributions were consistent over time, regardless of origin, resulting in small, insignificant measures of genetic differentiation among collections. This indicates that there were no year-to-year differences in allele frequencies between natural and hatchery-origin sockeye. In addition, the analyses found no differences between pre- and postsupplementation collections. Thus, it was concluded that the allele frequencies of the broodstock collections equaled the allele frequency of the natural collections.

It is important to note that no new information will be reported on genetics until the next five-year report (2018).

## Proportionate Natural Influence

Another method for assessing the genetic risk of a supplementation program is to determine the influence of the hatchery and natural environments on the adaptation of the composite population. This is estimated by the proportion of natural-origin fish in the hatchery broodstock ( pNOB ) and the proportion of hatchery-origin fish in the natural spawning escapement ( $\mathrm{pHOS} \mathrm{)}$. Proportionate Natural Influence (PNI) by iterating Ford's (2002) equations 5 and 6 to equilibrium, using a heritability of 0.3 and a selection strength of three standard deviations. The larger the PNI value, the greater the strength of selection in the natural environment relative to that of the hatchery environment. For the natural environment to dominate selection, PNI should be greater than 0.50 , and important integrated populations should have a PNI of at least 0.67 (HSRG/WDFW/NWIFC 2004).

The PNI values for the life of the program (brood years 1989-2011) are shown in Table 4.27. Throughout the program, PNI was consistently greater than 0.67 . The hatchery program was terminated in 2012.

Table 4.27. Proportionate Natural Influence (PNI) values for the Wenatchee sockeye supplementation program for brood years 1989-2016. NOS = number of natural-origin sockeye counted at Tumwater Dam; HOS = number of hatchery-origin sockeye counted at Tumwater Dam; NOB = number of natural-origin sockeye collected for broodstock; and $\mathrm{HOB}=$ number of hatchery-origin sockeye included in hatchery broodstock. $\mathrm{NP}=$ no hatchery program.

${ }^{\text {a }}$ Proportions of natural-origin and hatchery-origin spawners were determined from reading video tape at Tumwater Dam, adjusted for fish harvested in the Lake Wenatchee recreational fishery.
${ }^{\text {b }}$ PNI was calculated previously using PNI approximate equation 11 (HSRG 2009; their Appendix A). All PNI values presented here were recalculated by iterating Ford's (2002) equations 5 and 6 to equilibrium using a heritability of 0.3 and a selection strength of three standard deviations. C. Busack, NOAA Fisheries, 21 March 2016, provided the model for calculating PNI.

## Post-Release Survival and Travel Time

We used PIT-tagged fish to estimate survival rates and travel time (arithmetic mean days) of hatchery sockeye salmon from Lake Wenatchee to McNary Dam, and smolt to adult ratios (SARs) from release to detection at Bonneville Dam (Table 4.28). ${ }^{9}$ Over the seven brood years for which PIT-tagged hatchery fish were released, survival rates from Lake Wenatchee to McNary Dam ranged from 0.211 to 0.370; SARs from release to detection at Bonneville Dam ranged from 0.005 to 0.044 . Average travel time from Lake Wenatchee to McNary Dam ranged from 176 to 202 days.
Table 4.28. Total number of hatchery sockeye parr released with PIT tags, their survival and travel times (mean days) to McNary Dam, and smolt-to-adult (SAR) ratios for brood years 2005-2011. Standard errors are shown in parentheses.

| Brood year | Number of <br> sockeye released <br> with PIT tags | Survival to <br> McNary Dam | Travel time ${ }^{1}$ to <br> McNary Dam (d) | SAR to Bonneville <br> Dam |
| :---: | :---: | :---: | :---: | :---: |
| 2005 | 14,859 | $0.334(0.013)$ | $176.4(61.9)$ | $0.020(0.001)$ |
| 2006 | 14,764 | $0.370(0.030)$ | $202.0(9.1)$ | $0.044(0.002)$ |
| 2007 | 14,947 | $0.312(0.013)$ | $199.9(8.6)$ | $0.024(0.001)$ |
| 2008 | 14,858 | $0.307(0.020)$ | $192.9(35.7)$ | $0.015(0.001)$ |
| 2009 | 14,486 | $0.211(0.015)$ | $194.2(29.1)$ | $0.005(0.001)$ |
| 2010 | 5,039 | $0.302(0.048)$ | $191.7(26.6)$ | $0.014(0.002)$ |
| 2011 | 5,074 | $0.318(0.038)$ | $196.7(7.3)$ | $0.036(0.003)$ |

[^6]${ }^{1}$ Travel time is calculated from the date of release from the net pens in the fall, overwintering in Lake Wenatchee, to spring outmigration.

## Natural and Hatchery Replacement Rates

Natural replacement rates (NRR) were calculated as the ratio of natural-origin recruits (NOR) to the parent spawning population. Natural-origin recruits are naturally produced (wild) fish that survive to contribute to harvest (directly or indirectly), to broodstock, and to spawning grounds. We do not account for fish that died in route to the spawning grounds (migration mortality) or died just before spawning (pre-spawn mortality) (see Appendix B in Hillman et al. 2012). We calculated NORs with and without harvest. NORs without harvest include all returning fish that either returned to the basin or were collected as wild broodstock. NORs with harvest include all fish harvested and are based on a brood year harvest rates from the hatchery program. For brood years 1989-2010, NRR in the Wenatchee averaged 1.58 (range, 0.13-5.72) if harvested fish were not included in the estimate and 1.87 (range, 0.14-6.88) if harvested fish were included in the estimate (Table 4.29).

Hatchery replacement rates (HRR) were estimated as hatchery adult-to-adult returns. These rates should be greater than the NRRs and greater than or equal to 5.4 (the calculated target value in Hillman et al. 2013). The target value of 5.4 includes harvest. HRRs exceeded NRRs in 14 or 15 of the 23 years of data depending on if harvest was or was not included in the estimates (Table 4.29). Hatchery replacement rates for Wenatchee sockeye have equaled or exceeded the estimated target value of 5.4 in five of the 23 years (Table 4.29).
Table 4.29. Broodstock collected, spawning escapements, natural and hatchery-origin recruits (NOR and HOR), and natural and hatchery replacement rates (NRR and HRR; with and without harvest) for sockeye salmon in the Wenatchee River basin, 1989-2010.

## Juvenile-to-Adult Survivals

When possible, both parr-to-adult ratios (PAR) and smolt-to-adult ratios (SAR) were calculated for hatchery sockeye salmon. Ratios were calculated as the number of hatchery adult recaptures divided by the number of tagged hatchery parr released or the estimated number of smolts emigrating from Lake Wenatchee. Here, survival ratios were based on CWT returns, when available, or on the estimated number of hatchery adults recovered on the spawning grounds, in broodstock, and harvested. For the available brood years, PARs have ranged from 0.0001 to 0.0339 for hatchery sockeye salmon and SARs have ranged from 0.0002 to 0.0255 (Table 4.30).
Table 4.30. Parr-to-adult ratios (PAR) and smolt-to-adult ratios (SAR) for Wenatchee hatchery sockeye salmon, brood years 1990-2010; NA = not available.

| Brood year | Number of parr released | Number of smolts | Estimated adult recaptures | PAR | SAR |

### 4.8 ESA/HCP Compliance

## Smolt and Emigrant Trapping

ESA-listed spring Chinook and steelhead were encountered during operation of the Lower Wenatchee trap. ESA takes are reported in the steelhead (Section 3.8) and spring Chinook (Section 5.8) sections and will not be repeated here.

## Spawning Surveys

Sockeye spawning ground surveys conducted in the Wenatchee River basin during 2016 were consistent with ESA Section 10 Permit No. 1347. Because of the difficulty of quantifying the level of take associated with spawning ground surveys, the Permit does not specify a take level associated with these activities, even though it does authorize implementation of spawning ground surveys. Therefore, no take levels are reported. However, to minimize potential effects to established redds, wading was restricted to the extent practical and extreme caution was used to avoid established redds when wading was required.

## SECTION 5: WENATCHEE (CHIWAWA) SPRING CHINOOK

The goal of Chiwawa spring Chinook salmon supplementation is to achieve "No Net Impact" to the productivity of spring Chinook caused by the operation of the Rock Island Hydroelectric Project. The Rock Island Fish Hatchery Complex began operation in 1989 under funding from Chelan PUD. The Complex operated originally through the Rock Island Settlement Agreement, but since 2004 has operated under the Rock Island and Rocky Reach Anadromous Fish Agreement and Habitat Conservation Plans.

Adult spring Chinook are collected for broodstock at the Chiwawa Weir and Tumwater Dam. From 2011 through 2013, all spring Chinook broodstock were collected at the Chiwawa Weir in order to reduce passage delays caused by trapping at Tumwater Dam. Before 2009, the goal was to collect up to 379 adult spring Chinook for the program with natural-origin fish making up not less than $33 \%$ of the broodstock. In 2011, the Hatchery Committees reevaluated the amount of hatchery compensation needed to achieve NNI. Based on that evaluation, the goal of the program was revised. The current goal (beginning with brood year 2013) is to collect 74 natural-origin spring Chinook. The number collected cannot exceed $33 \%$ of the natural-origin spring Chinook returns to Tumwater. Beginning in 2014, previously PIT-tagged hatchery-origin Chiwawa spring Chinook are collected at Tumwater Dam, while the Chiwawa Weir is used to collect natural-origin brood for the Chiwawa spring Chinook program. Broodstock collection occurs from May through July at Tumwater with trapping occurring up to 24 hours per day, seven days a week and at the Chiwawa Weir with trapping occurring from 15 June to 1 August (not to exceed 15 cumulative trapping days) on a 24 -hour-up/24-hour-down schedule consistent with annual broodstock collection protocols.
Adult spring Chinook are spawned and reared at Eastbank Fish Hatchery. Juvenile spring Chinook are transferred from the hatchery to the Chiwawa Acclimation Facility in late September or early October. They are released volitionally from the Chiwawa Acclimation Facility during April the following year.

The production goal for the Chiwawa spring Chinook supplementation program up to brood year 2009 was to release 672,000 yearling smolts into the Chiwawa River at 12 fish per pound. Brood years 2010-2011, and 2012 were transition years to a reduced program of 298,000 smolts and 205,000 smolts, respectively. Beginning with the 2013 brood, the revised production goal is to release 144,026 smolts as part of a conservation program at 18 fish per pound. The Wenatchee spring Chinook safety-net program is now part of the Nason Creek spring Chinook program. Targets for fork length and weight are $155 \mathrm{~mm}(\mathrm{CV}=9.0)$ and 37.8 g , respectively. Over $90 \%$ of these fish are marked with CWTs. In addition, since 2006, juvenile spring Chinook have been PIT tagged annually.
With issuance of new ESA Section 10 permits in 2013, adult management (i.e., removal of excess hatchery-origin adults at dams, traps, and weirs, and in conservation fisheries) was implemented in 2014 to achieve pHOS and PNI goals for the Wenatchee spring Chinook programs.
Although this section of the report focuses on results from monitoring the Chiwawa spring Chinook program, information on spring Chinook collected throughout the Wenatchee River basin is also provided. Information specific to the Nason Creek spring Chinook conservation program is
presented in Section 6 and the White River Captive Broodstock Program is presented in Section 7.

### 5.1 Broodstock Sampling

This section focuses on results from sampling 2014-2016 Chiwawa spring Chinook broodstock, which were collected at the Chiwawa Weir and at Tumwater Dam, consistent with methods in the broodstock collections protocols (Tonseth 2014, 2015, and 2016). Some information for the 2016 return is not available at this time (e.g., age structure and final origin determination). This information will be provided in the 2017 annual report.

## Origin of Broodstock

Natural-origin adults made up between $31.3 \%$ and $100.0 \%$ of the Chiwawa spring Chinook broodstock for brood years 2014-2016 (Table 5.1). Natural and hatchery-origin adults were collected at Tumwater Dam and the Chiwawa Weir for return year 2016. Broodstock were trapped at Tumwater Dam from end of-May through mid-July 2016, and at the Chiwawa Weir from midJune through late-July. Hatchery-origin broodstock were collected at Tumwater Dam in 2016 to meet the Nason Creek Safety Net broodstock requirements and to fill potential shortfalls of naturalorigin broodstock requirements for the Chiwawa River Conservation program. Additional hatchery-origin broodstock were collected to ensure production obligations were achieved in the event that insufficient natural-origin collections could be made. A total of 21 hatchery-origin fish collected in 2016 were surplused at Eastbank Fish Hatchery.
Table 5.1. Numbers of wild and hatchery Chiwawa spring Chinook collected for broodstock, numbers that died before spawning, and numbers of Chinook spawned, 1989-2016. Unknown origin fish (i.e., undetermined by scale analysis, no CWT or fin clips, and no additional hatchery marks) were considered naturally produced.

${ }^{\text {a }}$ Pre-spawn loss represents the number of fish that died during the holding period before spawning. Mortality is the number of fish that were surplused following spawning.
${ }^{\mathrm{b}}$ The average and median represent the program before recalculation in 2011.
${ }^{\text {c }}$ The average and median represent the current program, which began in 2012. Origin determinations should be considered preliminary pending scale analyses.
${ }^{d}$ HOR Chiwawa spring Chinook were collected to meet both Chiwawa and Nason Creek obligations; broodstock and subsequent progeny were pooled together in the hatchery. About 12 Chiwawa HOR's were used to fulfill the Chiwawa Program; about 122 Chiwawa HOR's were used to fulfill the Nason Creek safety net obligation.
${ }^{\mathrm{e}}$ For the Chiwawa program, 36 hatchery-origin returns were collected in case the program fell short on natural-origin returns. After eye-up, all of the hatchery-origin recruit eggs were culled because fecundity of natural-origin recruits was high enough to meet the WxW program.

## Age/Length Data

Ages were determined from scales and/or coded wire tags (CWT) collected from broodstock. For both the 2014 and 2015 returns, most adults, regardless of origin, were age-4 Chinook (Table 5.2). All age-5 Chinook were natural-origin fish; hatchery-origin Chinook were all age-4 fish. There were no age-3 natural or hatchery-origin fish collected for broodstock.
Table 5.2. Percent of hatchery and wild spring Chinook of different ages (total age) collected from broodstock, 1991-2015.

${ }^{\text {a }}$ Comprised of age results for both Chiwawa and Nason Creek obligations.

There was little difference in mean lengths between hatchery and natural-origin broodstock of age4 Chinook in 2014 and 2015; however, age- 5 natural-origin Chinook in 2014 were larger than hatchery-origin broodstock (Table 5.3). All age-5 Chinook in 2015 were natural-origin fish.

Table 5.3. Mean fork length (cm) at age (total age) of hatchery and wild spring Chinook collected from broodstock, 1991-2015; $\mathrm{N}=$ sample size and $\mathrm{SD}=1$ standard deviation.

## Sex Ratios

Male spring Chinook in the 2014-2016 return years made up $49.2 \%$, $53.5 \%$, and $47.2 \%$, respectively, of the adults collected. This resulted in overall male to female ratios of 0.97:1.00, 1.15:1.00, and 0.89:1.00, respectively (Table 5.4). For the 2016 return year, natural-origin and hatchery-origin fish both consisted of a slightly lower proportion of males than females (Table 5.4).

Table 5.4. Numbers of male and female wild and hatchery spring Chinook collected for broodstock, 19892016. Ratios of males to females are also provided.

## Fecundity

Mean fecundities for the 2014-2016 returns of spring Chinook ranged from 4,045-4,847 eggs per female (Table 5.5). These fecundities were generally more than the overall average of 4,655 eggs per female, but were close to the expected fecundity of 4,400 eggs per female assumed in the broodstock protocols. For the 2016 return year, natural-origin Chinook produced more eggs per female than did hatchery-origin fish. This could be attributed to differences in size and age of hatchery and natural-origin fish described above (Tables 5.2 and 5.3).

Table 5.5. Mean fecundity of wild, hatchery, and all female spring Chinook collected for broodstock, 19892016; NA = not available.

# 5.2 Hatchery Rearing 

## Rearing History

## Number of eggs taken

Based on the unfertilized egg-to-release survival standard of $81 \%$, a total of 829,630 eggs were required to meet the program release goal of 672,000 smolts for brood years 1989-2010. For the 2011 and 2012 brood years, a total of 367,536 and 252,410 eggs were required to meet the release goals of 298,000 and 204,452 smolts, respectively. Since 2013, 169,442 eggs have been required to achieve a release goal of 144,026 smolts for the Chiwawa spring Chinook Program. Between 1989 and 2016, the egg take goal was reached only in 2001, 2015, and $2016^{10}$ (Table 5.6). The green egg takes for 2014-2016 brood years were $99.7 \%, 109.0 \%$, and $109.0 \%$ of program goals, respectively.

At the beginning of the Chiwawa spring Chinook program, the production level was set at 372,000 smolts. The primary reason for not meeting the egg take requirements included a lack of returning hatchery adults (because of program start up) and low wild fish abundance (along with no weir in the Chiwawa for first few years). Post ESA listing and issuance of Section 10(a)(1(A) permit 1196 in 1999, continued low abundance (hatchery and natural origin), as well as the permit limitation requiring a minimum of $33 \%$ natural-origin fish in the broodstock further constrained meeting the requisite egg take goal for a 672,000 program. In 2010, it was expected that recalculation of the mitigation obligation beginning with the 2012 brood year was going to result in a significant reduction in the production level and the Hatchery Committees subsequently agreed to reduce the production target to 298,000 in advance of recalculation to increase the likelihood of meeting the overall production goal. In 2011, the Joint Fisheries Parties developed the Wenatchee Basin Spring Chinook Management Plan, which split the program into a conservation and safety-net component; the conservation program using natural origin fish to meet recovery objectives and the safety net using returning adults from the conservation program to satisfy the balance of the production requirement.

Per amended Section 10(a)(1)(A) permit 18121, natural-origin broodstock is currently collected for the Chiwawa spring Chinook Program using PIT-tagged wild fish (tagged as juveniles) intercepted at Tumwater Dam and at the Chiwawa Weir. Operational limitations (e.g., flows, days per season, and bull trout encounters) reduce the opportunity to meet the natural-origin broodstock requirement, particularly in years of low adult abundance. Subsequently, to ensure the mitigation obligation is met, a component of hatchery adult returns are trapped and retained from Tumwater Dam during broodstock collection for the Nason Creek Program, which uses a composited broodstock (for the conservation component) identified through genetic analysis. The genetic analysis is used to prioritize those adults assigned with the highest probability to either the Nason or Chiwawa spawning aggregates, and excludes those assigned to the White River spawning aggregate.

* Although the program egg-take goal was achieved, the natural-origin egg-take goal was not.

## Number of acclimation days

Early rearing of the 2014 brood Chiwawa spring Chinook was similar to previous years with fish being held on well water before being transferred to the Chiwawa Acclimation Facility for final acclimation. Beginning in 2006 (2005 brood acclimation), modifications were made to the Chiwawa Acclimation Facility intakes so that Wenatchee River water could be applied to the Chiwawa River intakes during severe cold periods to prevent the formation of frazzle ice. During acclimation of the 2014 brood, fish were acclimated for 190 to 198 days on Chiwawa River water (Table 5.7).
Table 5.7. Number of days spring Chinook broods were acclimated and water source, brood years 19892014; NA = not available.

## Release Information

## Numbers released

The 2014 brood Chiwawa spring Chinook program achieved $100 \%$ of the 144,026 goal with about 144,360 smolts ( $126,330 \mathrm{WxW}$ and $18,030 \mathrm{HxH}$ ) being released volitionally into the Chiwawa River in 2016 (Table 5.8). Water-intake issues with the Nason spring Chinook program resulted in the transfer of the safety-net program to the Chiwawa Acclimation Facility. Release numbers in Table 5.8 reflect the inclusion of Nason Spring Chinook.
Table 5.8. Numbers of spring Chinook smolts tagged and released from the hatchery, brood years 19892013. The release target for Chiwawa spring Chinook is 144,026 smolts. For brood years 2012 to present, conservation program fish are not adipose fin clipped (they receive CWT only).

${ }^{\text {a }}$ This does not include the 226,456 eyed eggs that were planted in the Chiwawa River.
${ }^{\mathrm{b}}$ This high ELISA group was only adipose fin clipped and directly planted into Big Meadow Creek in May.
${ }^{\text {c }}$ This does not include 18,480 eyed eggs that were culled because of high ELISA.
${ }^{d}$ Brood years 2013 to present WxW spring Chinook are not adipose fin clipped (they receive CWT only); HxH Chinook are adipose fin clipped and receive a CWT.
${ }^{\text {e }}$ The total number of smolts released includes the HxH Nason Creek program that was transferred to the Chiwawa Acclimation Facility on 2-3 March 2016 because of water-intake concerns at the Nason Creek Acclimation Facility.
${ }^{\mathrm{f}}$ The HxH Nason Creek program that was released from the Chiwawa Acclimation Facility.

## Numbers tagged

The 2014 brood Chiwawa spring Chinook were $98 \%$ CWT (Table 5.8).
In 2016, a total of 10,207 WxW Chiwawa spring Chinook from the 2015 brood were PIT tagged at Eastbank Hatchery on 11-14 July 2016. These were tagged and released into raceway \#11. Fish were not fed during tagging or for two days before and after tagging. Fish averaged 87 mm in length and 8.0 g at time of tagging. These fish were transferred to the Chiwawa Acclimation Facility in October 2016.
Table 5.9 summarizes the number of hatchery spring Chinook that have been PIT-tagged and released into the Chiwawa River.

Table 5.9. Summary of PIT-tagging activities for Chiwawa hatchery spring Chinook, brood years 20052014.

| Brood year | Release year | Number of fish <br> tagged | Number of <br> tagged fish that <br> died | Number of tags <br> shed | Number of <br> tagged fish <br> released |

| 2014 | 2016 | 10,200 | 21 | 0 | 10,179 |

${ }^{a}$ This release consisted of 4,988 tagged Chinook that were released volitionally and 4,993 that were forced released.

## Fish size and condition at release

Spring Chinook from the 2014 brood were released as yearling smolts between 15 and 20 April 2016. Size at release ( 13 fpp ) was larger than the target of 18 fpp established for the program. The CV for fork length was $55 \%$ over the target (Table 5.10).
Table 5.10. Mean lengths (FL, mm), weight ( g and fish/pound), and coefficient of variation (CV) of spring Chinook smolts released from the hatchery, brood years 1989-2014. Size targets are provided in the last row of the table.

${ }^{\text {a }}$ Forced-release group.
${ }^{\mathrm{b}}$ Volitional-release group.
${ }^{\text {c }}$ This represents the combination of the WxW Chiwawa, HxH Chiwawa, and the HxH Nason Creek programs. The HxH Nason Creek program was transferred to the Chiwawa Acclimation Facility on 2-3 March 2016 because of water-intake concerns at the Nason Creek Acclimation Facility.

## Survival Estimates

Overall survival of the 2014 brood Chiwawa spring Chinook from green (unfertilized) egg to release was above the standard set for the program (Table 5.11). There was higher than expected survivals throughout most stages except unfertilized to eye-egg, contributing to increased program performance. Pre-spawn survival of adults was also above the standard set for the program.

Table 5.11. Hatchery life-stage survival rates (\%) for spring Chinook, brood years 1989-2014. Survival standards or targets are provided in the last row of the table.

${ }^{\text {a }}$ Survival estimates do not include the 18,840 eyed eggs that were culled because of high ELISA levels.
${ }^{\text {b }}$ Survival estimates do not include the HxH Nason Creek program that was transferred to the Chiwawa Acclimation Facility because of water-intake concerns at the Nason Creek Acclimation Facility.

### 5.3 Disease Monitoring

Results of 2016 adult broodstock bacterial kidney disease (BKD) monitoring indicated that most females had ELISA values less than 0.199. About $81.1 \%$ of females had ELISA values less than 0.120 , which would have required about $18.9 \%$ of the progeny to be reared at densities not to exceed 0.06 fish per pound (Table 5.12).
For the 2014 brood, a formalin drip was used shortly after transfer to the Chiwawa Acclimation Facility to prevent infection associated with stress caused by the transfer. No significant health issues were encountered for the remainder of juvenile rearing.

Table 5.12. Proportion of bacterial kidney disease (BKD) titer groups for the Chiwawa spring Chinook broodstock, brood years 1996-2016. Also included are the proportions to be reared at either 0.125 fish per pound or 0.060 fish per pound.

${ }^{\text {a }}$ Individual ELISA samples were not collected before the 1996 brood.
${ }^{\mathrm{b}}$ ELISA values from broodstock BKD testing dictate what density the progeny of the broodstock are reared. Progeny of broodstock with high ELISA values are reared at lower density.
${ }^{c}$ Comprised of HOR's used for both Chiwawa and Nason Creek obligations.

### 5.4 Natural Juvenile Productivity

During 2016, juvenile spring Chinook were sampled at the Lower Wenatchee, Nason Creek, White River, and Chiwawa River traps and counted during snorkel surveys within the Chiwawa River basin. Results from sampling at the Nason Creek Trap are provided in Section 6 and from the White River Trap in Section 7.

## Parr Estimates

Based on snorkel surveys, a total of 140,172 ( $\pm 10 \%$ ) subyearling and $282( \pm 43 \%)$ yearling spring Chinook were estimated in the Chiwawa River basin in August 2016 (Table 5.13 and 5.14). During the survey period 1992-2016, numbers of subyearling and yearling Chinook have ranged from 5,815 to 149,563 and 5 to 967 , respectively, in the Chiwawa River basin (Table 5.13 and 5.14; Figure 5.1). Numbers of all fish counted in the Chiwawa River basin are reported in Appendix A.
Table 5.13. Total numbers of subyearling spring Chinook estimated in different streams in the Chiwawa River basin during snorkel surveys in August 1992-2016; NS = not sampled.

## Chinook Salmon

Age-0

Age-1+

Figure 5.1. Numbers of subyearling and yearling Chinook salmon within the Chiwawa River Basin in August 1992-2016; ND = no data.

Juvenile Chinook were distributed contagiously among reaches in the Chiwawa River. Their densities were highest in the upper portions of the basin, with the highest densities within tributaries. Juvenile Chinook were most abundant in multiple channels and least abundant in glides and riffles. Most Chinook associated closely with woody debris in multiple channels. These sites (multiple channels) made up $16 \%$ of the total area of the Chiwawa River basin, but they provided habitat for $56 \%$ of all subyearling Chinook in the basin in 2016. In contrast, riffles made up $54 \%$ of the total area, but provided habitat for only $8 \%$ of all juvenile Chinook in the Chiwawa River basin. Pools made up $24 \%$ of the total area and provided habitat for $35 \%$ of all juvenile Chinook in the basin. Virtually no Chinook used glides that lacked woody debris.

Mean densities of juvenile Chinook in two reaches of the Chiwawa River were generally less than those in corresponding reference areas on Nason Creek and the Little Wenatchee River (Figure 5.2). Within both the Chiwawa River and its reference areas, pools and multiple channels consistently had the highest densities of juvenile Chinook.

Figure 5.2. Comparison of the 23 -year means of subyearling spring Chinook densities within state/habitat types in reaches 3 and 8 of the Chiwawa River and their matched reference areas on Nason Creek and the Little Wenatchee River. $\mathrm{NC}=$ natural channel; $\mathrm{S}=$ straight channel; $\mathrm{EB}=$ eroded banks; $\mathrm{MC}=$ multiple channel. There was no sampling in 2000 and no sampling within reference areas in 1992.

## Smolt and Emigrant Estimates

Numbers of spring Chinook smolts and emigrants were estimated at the Chiwawa and Lower Wenatchee traps in 2016.

## Chiwawa Trap

The Chiwawa Trap operated between 2 March and 21 November 2016. During that time, the trap was inoperable for 72 days because of high and low river flows, debris, major hatchery releases, and mechanical issues. The trap operated in a single position throughout the sampling season. Daily trap efficiencies were estimated for each age class of fish (e.g., subyearling and yearling). The daily number of fish captured was expanded by the estimated trap efficiency to estimate daily total emigration. Monthly captures of all fish and results of mark-recapture efficiency tests at the Chiwawa Trap are reported in Appendix B.

Wild yearling spring Chinook (2014 brood year) were primarily captured in March and April 2016 (Figure 5.3). A significant relationship between trap efficiency and river flow was found $\left(\mathrm{R}^{2}=\right.$ $0.875 ; \mathrm{P}<0.028$ ) and the total number of wild yearling Chinook emigrating from the Chiwawa River was estimated at $37,170( \pm 6,524 ; 95 \% \mathrm{CI})$. Combining the total number of subyearling spring Chinook $(77,510 \pm 9,074)$ that emigrated during the fall of 2015 with the total number of yearling Chinook $(37,170 \pm 6,524)$ that emigrated during 2016, the total emigrant estimate for brood year 2014 was $114,680( \pm 12,268)$ (Table 5.15). No non-trapping estimate was calculated for brood year 2014 (see Appendix B).

## Juvenile Spring Chinook

Figure 5.3. Monthly captures of wild subyearling, wild yearling, and hatchery yearling spring Chinook at the Chiwawa Trap, 2016.

Table 5.15. Numbers of redds and juvenile spring Chinook at different life stages in the Chiwawa River basin for brood years 1991-2016; NS = not sampled.

${ }^{a}$ The estimated number of smolts (yearlings) that are produced entirely within the Chiwawa River basin. Smolt estimates for brood years 1992-1996 were calculated with a mark-recapture model; brood years 1997-present were calculated with a flow model.
${ }^{\mathrm{b}}$ Estimate only includes numbers of Chinook in the Chiwawa River. Tributaries were not sampled at that time.

Wild subyearling spring Chinook (2015 brood year) were captured between March and November 2016. Based on capture efficiencies, the total number of wild subyearling (fry and parr) Chinook from the Chiwawa River basin was $145,971( \pm 48,393)$. Removing fry from the estimate, a total of 80,543 ( $\pm 27,967$ ) subyearling parr emigrated from the Chiwawa River basin in 2016. Although subyearling parr migrated during all months of sampling, the majority ( $83 \%$ ) migrated during March, June, July, August, and October (Figure 5.3).

Yearling spring Chinook sampled in 2016 averaged 91 mm in length, 8.3 g in weight, and had a mean condition of 1.06 (Table 5.16). These size estimates were similar to the overall mean of yearling spring Chinook sampled in previous years (overall means: $93 \mathrm{~mm}, 9.1 \mathrm{~g}$, and condition of 1.08). Subyearling spring Chinook sampled in 2016 at the Chiwawa Trap averaged 71 mm in length, averaged 4.5 g , and had a mean condition of 1.10 (Table 5.16). In general, subyearlings were slightly smaller than previous years (overall means, $76 \mathrm{~mm}, 5.3 \mathrm{~g}$, and condition of 1.09).

Table 5.16. Mean fork length (mm), weight (g), and condition factor of subyearling (excluding fry) and yearling spring Chinook collected in the Chiwawa Trap, 1996-2016. Numbers in parentheses indicate 1 standard deviation.

| Sample year | Life stage | Sample size ${ }^{\text {a }}$ | Mean size |  |  |

${ }^{\text {a }}$ Sample size represents the number of fish that were measured for both length and weight.

## Lower Wenatchee Trap

The lower Wenatchee Trap operated in a new location beginning in 2013. Hence, historic flowdischarge relationships are invalid and new models to estimate trap efficiency are being developed for all species.

The Lower Wenatchee Trap operated between 29 January and 26 July 2016. During that time, the trap was inoperable for 23 days because of high and low river discharge, debris, elevated river temperature, large hatchery releases, and mechanical issues. During the sampling period, a total of 610 wild yearling Chinook, 27,407 wild subyearling Chinook (mostly summer Chinook), and 7,701 hatchery yearling Chinook were captured at the Lower Wenatchee Trap. Based on capture efficiencies and river discharge, a significant model was developed ( $\mathrm{R}^{2}=0.620, \mathrm{P}<0.02$ ). The flow efficiency model estimated the total number of wild yearling Chinook that emigrated past the Lower Wenatchee Trap at 36,752 ( $\pm 5,330 ; 95 \%$ CI) (Table 5.17). Monthly captures of all fish collected at the Lower Wenatchee Trap are reported in Appendix B.

Table 5.17. Numbers of redds and wild spring Chinook smolts produced in the Wenatchee River basin for brood years 2000-2014; NS = not sampled. From 2000-2010 the trap operated at Monitor; from 2013 to present the trap operated near Cashmere.

| Brood year | Number of redds | Egg deposition | Number of smolts produced <br> within Wenatchee River <br> basin |
| :---: | :---: | :---: | :---: |
| 2000 | 350 | $1,758,050$ | 76,643 |

Yearling spring Chinook sampled in 2016 at the Lower Wenatchee Trap averaged 94 mm in length, 9.0 g in weight, and had a mean condition of 1.06 (Table 5.18). These size estimates were similar to the overall mean of yearling spring Chinook sampled in previous years (overall means: 98 mm , 10.5 g , and condition of 1.10 ).

Table 5.18. Mean fork length (mm), weight (g), and condition factor of yearling spring Chinook collected in the Lower Wenatchee Trap, 2000-2016. From 2000-2010 the trap operated at Monitor; from 2013 to present the trap operated near Cashmere. Numbers in parentheses indicate 1 standard deviation.

${ }^{\text {a }}$ Sample size represents the number of fish that were measured for both length and weight.

## PIT Tagging Activities

As part of the Comparative Survival Study (CSS) and PUD studies, a total of 14,158 wild juvenile Chinook (10,888 subyearling and 3,270 yearlings) were PIT tagged and released in 2016 in the Wenatchee River basin (Table 5.19a). Most of these (71.2\%) were tagged at the Chiwawa trap. See Appendix C for a complete list of all fish captured, tagged, lost, and released.
Table 5.19a. Numbers of wild Chinook that were captured, tagged, and released at different locations within the Wenatchee River basin, 2016. Numbers of fish that died or shed tags are also given.

## Freshwater Productivity

Both productivity and survival estimates for different life stages of spring Chinook in the Chiwawa River basin are provided in Table 5.20. Estimates for brood year 2014 fall within the ranges estimated over the period of brood years 1991-2014. During that period, freshwater productivities ranged from 125-1,015 parr/redd, 39-673 smolts/redd, and 124-834 emigrants/redd. Survivals during the same period ranged from 2.7-19.1\% for egg-parr, $0.9-14.5 \%$ for egg-smolt, and 2.9$18.0 \%$ for egg-emigrants. Overwinter survival rates for juvenile spring Chinook within the Chiwawa River basin have ranged from 15.7-100.0\%.
Table 5.20. Productivity (fish/redd) and survival (\%) estimates for different juvenile life stages of spring Chinook in the Chiwawa River basin for brood years 1991-2014; ND = no data. These estimates were derived from data in Table 5.15.

${ }^{\text {a }}$ These estimates include Chiwawa smolts produced only within the Chiwawa River basin.
${ }^{\mathrm{b}}$ These estimates represent overwinter survival within the Chiwawa River basin. It does not include Chiwawa smolts produced outside the Chiwawa River basin.

Seeding level (egg deposition) explained most of the variability in productivity and survival of juvenile spring Chinook in the Chiwawa River basin. That is, for estimates based on "within-Chiwawa-Basin" life stages (e.g., parr and smolts), survival and productivity decreased as seeding levels increased (Figure 5.4). This suggests that density dependence regulates juvenile productivity and survival within the Chiwawa River basin. This form of population regulation is less apparent with total emigrants. However, one would expect the number of emigrants to increase as seeding levels exceed the rearing capacity of the Chiwawa River basin.

## Juvenile Spring Chinook

Figure 5.4. Relationships between seeding levels (egg deposition) and juvenile life-stage survivals and productivities for Chiwawa spring Chinook, brood years 1991-2014. Smolts represent yearling Chinook produced within the Chiwawa River basin.

## Population Carrying Capacity

Population carrying capacity $(K)$ is defined as the maximum equilibrium population size estimated with population models (e.g., logistic equation, Beverton-Holt model, hockey stick model, and the

Ricker model). ${ }^{11}$ Maximum equilibrium population size is generated from density dependent mechanisms that reduce population growth rates as population size increases (negative density dependence). This is referred to as compensation. Population size fluctuates about the maximum equilibrium size because of variability in vital rates that are unrelated to density (density independent factors) and measurement error. In this section, we estimate parr and smolt carrying capacities using the smooth hockey stick stock-recruitment model (see Appendix C in Hillman et al. 2012 for a detailed description of methods). This model explains most of the information contained in the juvenile spring Chinook data (see Appendix A).

Based on the smooth hockey stick model, the population carrying capacity for spring Chinook parr in the Chiwawa River basin is 113,801 parr ( $95 \%$ CI: $94,343-139,922$ ) (Figure 5.5). The capacity for spring Chinook smolts is 45,161 ( $95 \%$ CI: $34,226-55,445$ ) (Figure 5.6). Here, smolts are defined as the number of yearling spring Chinook produced entirely within the Chiwawa River basin. These estimates reflect current conditions (most recent two decades) within the Chiwawa River basin. Land use activities such as logging, mining, roads, development, and recreation have altered the historical conditions of the watershed. Thus, the estimated population capacity estimates may not reflect historical capacities for spring Chinook parr and smolts in the Chiwawa River basin.

Figure 5.5. Relationship between spawners and number of parr produced in the Chiwawa River basin. Population carrying capacity ( $K$ ) was estimated using the smooth hockey stick model, which explained most of the information in the data.

[^8]
## Chiwawa Spring Chinook Smooth Hockey Stick

Figure 5.6. Relationship between spawners and number of yearling smolts produced in the Chiwawa River basin. Population carrying capacity ( $K$ ) was estimated using the smooth hockey stick model, which explained most of the information in the data.
We tracked the precision of the smooth hockey stick parameters for Chiwawa spring Chinook smolts over time to see if precision improves with additional years of data, and the parameters and statistics stabilize over time. Examination of variation in the alpha $(A)$ and beta $(B)$ parameters of the smooth hockey stick model and their associated standard errors and confidence intervals indicates that the parameters appear to stabilize after 19 years of smolt and spawning escapement data (Table 5.21; Figure 5.7). This was also apparent in the estimates of population carrying capacity (Figure 5.8). That is, after 19 years of data, additional years of data had relatively little effect on the parameters of the smooth hockey stick model and its statistics. This observation will change if more extreme spawning escapements occur in the future or density independent factors overwhelm the influence of density dependent factors.

Table 5.21. Estimated parameters and statistics associated with fitting the smooth hockey stick model to spawning escapement and smolt data. Smolts represent numbers of smolts produced entirely within the Chiwawa River basin. $A=$ alpha parameter; $B=$ beta parameter; $\mathrm{SE}=$ standard error (estimated from 5,000 bootstrap samples); and $r^{2}=$ coefficient of determination. Spawners represent the stock size needed to achieve population capacity.

## Chiwawa Spring Chinook

 Hockey Stick Model

Figure 5.7. Time series of alpha and beta parameters and $95 \%$ confidence intervals for the smooth hockey stick model that was fit to Chiwawa spring Chinook smolt and spawning escapement data. Confidence intervals were estimated from 5,000 bootstrap samples.

## Chiwawa Spring Chinook Hockey Stick Model

Figure 5.8. Time series of population carrying capacity estimates derived from fitting the smooth hockey stick model to Chiwawa spring Chinook smolt and spawning escapement data.

### 5.5 Spawning Surveys

Surveys for spring Chinook redds were conducted during the last week of July through September 2016 in the Chiwawa River (including Rock, Chikamin, and Phelps creeks), Nason Creek, Icicle Creek, Peshastin Creek (including Ingalls Creek), Upper Wenatchee River (including Chiwaukum Creek), Little Wenatchee River, and the White River (including the Napeequa River and Panther Creek).

Spawning escapement for spring Chinook was calculated as the total number of redds times the male-to-female ratio (i.e., fish per redd expansion factor) estimated from broodstock and fish sampled at adult trapping sites. ${ }^{12}$ Beginning with return year 2015, WDFW used the Gaussian area-under-the-curve (AUC) method (Millar et al. 2012) to estimate the number of redds within survey reaches (see Appendix J). The number of redds within each reach were then divided by the mean net error (ratio of observed redds to true number of redds) to estimate the "true" number of redds within each reach. The Mean net error was modeled based on covariates such as surveyor experience, channel complexity (mean thalweg CV), and observed redd density (number of redds per km).

[^9]
## Redd Counts

A total of 554 spring Chinook redds were counted in the Wenatchee River basin in 2016 (Table 5.22). This is lower than the average of 674 redds counted during the period 1989-2015 in the Wenatchee River basin. Most spawning occurred in the Chiwawa River ( $56.3 \%$ or 312 redds) (Table 5.22; Figure 5.9). Nason Creek contained 15.3\% ( 85 redds), Icicle Creek contained $13.0 \%$ ( 72 redds), White River contained $7.9 \%$ ( 44 redds), Little Wenatchee contained $4.0 \%$ ( 22 redds), the Upper Wenatchee River 3.1\% ( 17 redds), and Peshastin Creek contained $0.4 \%$ ( 2 redds).
Table 5.22. Numbers of spring Chinook redds counted (not "true" estimates) within different streams or watersheds within the Wenatchee River basin, 1989-2016. WDFW began full implementation of adult management in 2014.

| Sample year | Number of spring Chinook redds |  |  |  |  |  |  |  |

| 2015 | 543 | 85 | 28 | 70 | 55 | 132 | 10 | 923 |
| 2016 | 312 | 85 | 22 | 44 | 17 | 72 | 2 | 554 |

| Sample <br> year | Number of spring Chinook redds |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Chiwawa | Nason | Little <br> Wenatchee | White | Wenatchee <br> River | Icicle | Peshastin | Total |  |
| Average | 329 | 142 | 28 | 35 | 47 | 70 | 10 | 670 |  |
| Median | 300 | 102 | 27 | 29 | 32 | 45 | 4 | 581 |  |

* Redd counts in Peshastin Creek in 2001 and 2002 were elevated because the U.S. Fish and Wildlife Service planted 487 and 350 spring Chinook adults, respectively, into the stream. These counts were not included in the total or average calculations.

## Spring Chinook Redds

River/Watershed
Figure 5.9. Percent of the total number of spring Chinook redds counted in different streams/watersheds within the Wenatchee River basin during August through September 2016.

As noted above, since 2015, WDFW has estimated the "true" number of redds within survey areas in the Wenatchee River basin using the Gaussian area-under-the-curve method. Based on two years of data, the average difference between the observed (counted) and true estimate is about 105 redds (Table 5.23).

Table 5.23. Comparison of the observed number and estimated "true" number of spring Chinook redds within different streams/watersheds within the Wenatchee River basin, 2015-2016.

| Survey stream | Survey year |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
|  | $\mathbf{2 0 1 5}$ |  | 2016 |  |
|  | Observed | Estimated | Observed | Estimated |

| Total | $\mathbf{7 8 0}$ | $\mathbf{9 0 5}$ | $\mathbf{5 5 4}$ | $\mathbf{6 3 8}$ |

## Redd Distribution

Spring Chinook redds were not evenly distributed among reaches within survey streams in 2016 (Table 5.24). Most of the spawning in the Chiwawa River basin occurred in Reaches 1 through 6. About $66 \%$ of the spawning in the Chiwawa River basin occurred in the lower two reaches (RKM 0.0-36.97; from the mouth to Rock Creek). Relatively few fish spawned in Rock and Chikamin creeks. The spatial distribution of redds in Nason Creek was weighted towards Reach 3, having $45 \%$ of the Nason Creek redds. In the Little Wenatchee River, about $89 \%$ of all spawning occurred in Reach 3 (RKM 9.2-14.0; Lost Creek to Falls). On the White River, $81 \%$ of the spawning occurred in Reach 3 (RKM 20.3-23.3; Napeequa River to Grasshopper Meadows). In the Wenatchee River about $50 \%$ of the fish spawned downstream from the mouth of the Chiwawa River, $41 \%$ spawned upstream from the mouth, and about $9 \%$ spawned in Chiwaukum Creek. In Icicle Creek, about 85\% of spawning occurred in Reach 2 (RKM 4.9-6.7; Hatchery to Sleeping Lady). All the spawning in Peshastin Creek occurred upstream from the confluence with Camas Creek (RKM 9.0).

Table 5.24. Numbers (both observed and estimated) and proportions of spring Chinook redds estimated within different streams/watersheds within the Wenatchee River basin during August through September 2016. NS = not surveyed. See Table 2.8 for description of survey reaches.

| Stream/watershed | Reach | Observed number of redds | Estimated number of redds | Proportion of estimated redds within stream/watershed |
| :---: | :---: | :---: | :---: | :---: |
| Chiwawa | Chiwawa 1 (C1) | 56 | 64 | 0.18 |

|  |  |  |  |  |$]$

${ }^{\text {a }}$ Reach H1 of the White River was surveyed once during the peak of the season to verify that no spawning was occurring in the lower portion of the river.

## Spawn Timing

Spring Chinook began spawning during the last week of July in Nason Creek and the second week of August in the Chiwawa River. Spawning began the third week of August in the Little Wenatchee and White rivers, the fourth week of August in Icicle Creek, the fifth week of August in Peshastin Creek, and the first week of September in the Wenatchee River (Figure 5.10). Spawning peaked the last week of August in Icicle Creek and the Little Wenatchee River. The Chiwawa River and Nason Creek peaked during the first week of September. The White River peaked during the second week of September and the Wenatchee River peaked during the fourth week of September.

The 11 redds observed on the Wenatchee River during the fourth week of September may have been present the previous week when no survey occurred. Peshastin Creek had two redds, one occurring the last week of August and one during the second week of September. Chinook completed spawning by the end of September.

## Spring Chinook Redds

Figure 5.10. Proportion of spring Chinook redds counted during different weeks in different sampling streams within the Wenatchee River basin, August through September 2016.

## Spawning Escapement

Spawning escapement for spring Chinook was calculated as the observed number of redds times the male-to-female ratio (i.e., fish per redd expansion factor) estimated from broodstock and fish sampled at adult trapping sites. ${ }^{13}$ The estimated fish per redd ratio for spring Chinook upstream from Tumwater in 2016 was 1.83 (based on sex ratios estimated at Tumwater Dam). The estimated fish per redd ratio for spring Chinook downstream from Tumwater (Icicle and Peshastin creeks) was 1.81 (derived from broodstock collected at the Leavenworth National Fish Hatchery). Multiplying these ratios by the number of redds counted in the Wenatchee River basin resulted in a total spawning escapement of 1,012 spring Chinook (Table 5.25). The Chiwawa River basin had the highest spawning escapement ( 574 Chinook), while Peshastin Creek had the lowest (4 Chinook).

[^10]Table 5.25. Number of observed redds, fish per redd ratios, and total spawning escapement for spring Chinook in the Wenatchee River basin, 2016. Spawning escapement was estimated as the product of redds times fish per redd.

| Sampling area | Total number of redds | Fish/redd | Total spawning escapement* |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Chiwawa | 312 | 1.83 | 571 |  |  |  |  |
| Nason | 85 | 1.83 | 156 |  |  |  |  |
| Upper Wenatchee River | 17 | 1.83 | 31 |  |  |  |  |
| Icicle | 72 | 1.81 | 130 |  |  |  |  |
| Little Wenatchee | 22 | 1.83 | 40 |  |  |  |  |
| White | 44 | 1.83 | 81 |  |  |  |  |
| Peshastin | 2 | 1.81 | 4 |  |  |  |  |
| Total |  |  |  |  | $\mathbf{5 5 4}$ | -- | $\mathbf{1 , 0 1 2}$ |

* Spawning escapement estimate is based on total number of observed redds by stream. If escapement is calculated at the reach scale, then the total escapement may vary from what is shown here because of rounding errors.

The estimated total spawning escapement of 1,012 spring Chinook in 2016 was less than the overall average of 1,367 spring Chinook (Table 5.26). The escapement in the Chiwawa River basin in 2016 was 3.7 times the escapement in Nason Creek, the second most abundant escapement in the Wenatchee River basin (Table 5.26).

Table 5.26. Spawning escapements for spring Chinook in the Wenatchee River basin for return years 19892016; NA = not available.

| Return year | Upper basin spawning escapement |  |  |  |  |  | Lower basin spawning escapement |  |  | Total |

${ }^{\text {a }}$ In 2004, the fish/redd expansion estimate of 3.56 was applied to the Chiwawa River only and 3.00 fish/redd was applied to the rest of the upper basin.

### 5.6 Carcass Surveys

Surveys for spring Chinook carcasses were conducted during August through September 2016 in the Chiwawa River (including Rock, Chikamin, and Phelps creeks), Nason Creek, Icicle Creek, Peshastin Creek (including Ingalls Creek), Upper Wenatchee River (including Chiwaukum Creek), Little Wenatchee River, and White River (including the Napeequa River and Panther Creek).

## Number sampled

A total of 362 spring Chinook carcasses were sampled during August through September in the Wenatchee River basin (Table 5.27). Most were sampled in the Chiwawa River basin ( $58 \%$ or 211 carcasses) and Nason Creek ( $26 \%$ or 95 carcasses) (Figure 5.11). A total of 25 carcasses were sampled in Icicle Creek, 13 in the Wenatchee River, 13 in the White River, and 5 in the Little Wenatchee River.

* The number of carcasses sampled in the Wenatchee River in 2016 include two recovered in reach (W6) just downstream from the mouth of Icicle Creek.

## Spring Chinook Carcasses

River/Watershed
Figure 5.11. Percent of the total number of spring Chinook carcasses sampled in different streams/watersheds within the Wenatchee River basin during August through September 2016.

## Carcass Distribution and Origin

Spring Chinook carcasses were not evenly distributed among reaches within survey streams in 2016 (Table 5.28). Most of the carcasses (71\%) in the Chiwawa River basin occurred in Reaches

1 and 2 (downstream from Rock Creek). In Nason Creek, most carcasses (51\%) were collected in Reach 3 and the fewest (8\%) in Reach 4. Most carcasses in the Little Wenatchee River were sampled in Reach 3 (Lost Creek to Rainy Creek). On the White River, most (85\%) occurred in Reach 3 (Napeequa River to Grasshopper Meadows). On the Wenatchee River, $62 \%$ of the carcasses were found upstream from the confluence of the Chiwawa River and $38 \%$ were found downstream from the confluence. Most of the carcasses in Icicle Creek (60\%) were found in Reach 2 (Hatchery to Sleeping Lady). No carcasses were found in Peshastin Creek.

${ }^{\text {a }}$ Reach Wen 6 is not a survey reach for spring Chinook surveys; however, in 2016 two carcasses were sampled during a spring Chinook survey on the Icicle River. The carcasses were located downstream of the confluence of the Icicle River and Wenatchee River.

Final origin was determined for 208 of the 211 carcasses sampled in the Chiwawa River basin in 2016. Of those 208, $30 \%$ were hatchery fish (Table 5.29). In the Chiwawa River basin, the spatial distribution of hatchery and wild fish was not equal (Table 5.29). A larger percentage of hatchery fish were found in the lower reaches ( C 1 and C 2 ; i.e., Mouth to Rock Creek). This general trend was also apparent in the pooled data (Figure 5.12).

Table 5.29. Numbers of wild and hatchery spring Chinook carcasses sampled within different reaches in the Chiwawa River basin, 1993-2016. Numbers represent recovered carcasses that had definitive origins. See Table 2.8 for description of survey reaches.

## Spring Chinook Carcass Distribution

Figure 5.12. Distribution of wild and hatchery produced carcasses in different reaches in the Chiwawa River basin, 1993-2016; Chik = Chikamin Creek and Rock $=$ Rock Creek. Reach codes are described in Table 2.8.

## Sampling Rate

Overall, $36 \%$ of the estimated total spawning escapement of spring Chinook in the Wenatchee River basin was sampled in 2016 (Table 5.30). Sampling rates among streams/watershed varied from 0 to $61 \%$.

Table 5.30. Number of redds and carcasses, total spawning escapement, and sampling rates for spring Chinook salmon in the Wenatchee River basin, 2016.

| Sampling area | Total number of <br> observed redds | Total number of <br> carcasses | Total spawning <br> escapement | Sampling rate |
| :--- | :---: | :---: | :---: | :---: |

| White | 69 (4.0) | 66 (6.2) |
| Peshastin | -- | -- |
| Total | 62 (11.5) | 64 (6.3) |

### 5.7 Life History Monitoring

Life history characteristics of spring Chinook were assessed by examining carcasses on spawning grounds and fish collected at broodstock collection sites, and by reviewing tagging data and fisheries statistics.

## Migration Timing

In 2016, there was a small difference in migration timing of hatchery and wild spring Chinook past Tumwater Dam (Table 5.32a and b; Figure 5.13). Hatchery fish arrived at the dam later than did wild fish, but ended their migration earlier than did wild fish. This same pattern was also observed in the overall average. Most hatchery and wild spring Chinook migrated upstream past Tumwater Dam during June and July (Figure 5.13).

Table 5.32a. The Julian day and date that $10 \%, 50 \%$ (median), and $90 \%$ of the wild and hatchery spring Chinook salmon passed Tumwater Dam, 1998-2016. The average Julian day and date are also provided. Migration timing is based on video sampling at Tumwater. Data for 1998 through 2003 were based on videotapes and broodstock trapping and may not reflect the actual number of hatchery spring Chinook. All spring Chinook were visually examined during trapping from 2004 to present.

| Survey year | Origin | Spring Chinook Migration Time (days) |  |  |  |  |  |  |  | Sample <br> size |

Table 5.32b. The week that $10 \%, 50 \%$ (median), and $90 \%$ of the wild and hatchery spring Chinook salmon passed Tumwater Dam, 1998-2016. The average week is also provided. Migration timing is based on video sampling at Tumwater. Data for 1998 through 2003 were based on videotapes and broodstock trapping and may not reflect the actual number of hatchery spring Chinook. All spring Chinook were visually examined during trapping from 2004 to present.

## Spring Chinook Migration Timing

Figure 5.13. Proportion of wild and hatchery spring Chinook observed (using video) passing Tumwater Dam each week during their migration period May through September; data were pooled over survey years 1998-2016.

## Age at Maturity

Most of the wild and hatchery spring Chinook sampled during the period 1994-2016 in the Chiwawa River basin were age-4 fish (total age) (Table 5.33; Figure 5.14). On average, hatchery fish made up a higher percentage of age- 3 Chinook than did wild fish. In contrast, a higher proportion of age- 5 wild fish returned than did age- 5 hatchery fish. Thus, wild fish tended to return at an older age than hatchery fish.

Table 5.33. Proportions of wild and hatchery spring Chinook of different ages (total age) sampled on spawning grounds in the Chiwawa River basin, 1994-2016.

| Sample year | Origin | Total age |  |  |  |  | Sample size |

## Spring Chinook Age Structure

Figure 5.14. Proportions of wild and hatchery spring Chinook of different total ages sampled at the Chiwawa Weir and on spawning grounds in the Chiwawa River basin for the combined years 1994-2016.

## Size at Maturity

On average, hatchery and wild spring Chinook of a given age differed slightly in length (Table 5.34). Differences were usually no more than 4 cm between hatchery and wild fish of the same age.

Table 5.34. Mean lengths ( POH in $\mathrm{cm} ; ~ \pm 1 \mathrm{SD}$ ) and sample sizes (in parentheses) of different ages (total age) of male and female spring Chinook of wild and hatchery-origin sampled in the Chiwawa River basin, 1994-2016. Return years 2004-2016 include carcasses and live fish PIT-tag detections. In addition, 2005 and 2006 include fish released at the weir.

| Return year | Total age | Mean length (cm) |  |  |  |

## Contribution to Fisheries

Nearly all the harvest on hatchery-origin Chiwawa spring Chinook occurs within the Columbia River basin. Ocean catch records (Pacific Fishery Management Council) indicate that very few Upper Columbia spring Chinook are taken in ocean fisheries. Most of the harvest on hatcheryorigin Chiwawa spring Chinook occurs in the Lower Columbia River fisheries, which are managed by the states and tribes pursuant to management plans developed in U.S. v Oregon. The Lower Columbia River fisheries occur during what is referred to in U.S.v Oregon as the winter, spring, and summer seasons, which begin in February and ends 31 July of each year. The Tribal fishery occurs upstream from Bonneville Dam, but primarily in Zone 6, the area between Bonneville and McNary dams; the non-treaty commercial fisheries occur in Zones 1-5, which are downstream from Bonneville Dam. The non-treaty recreational (sport) fishery occurs in the lower mainstem.
The total number of hatchery-origin spring Chinook captured in different fisheries has been relatively low (Table 5.35). The largest harvest occurred on the 2008 brood year.
Table 5.35. Estimated number and percent (in parentheses) of hatchery-origin Chiwawa spring Chinook captured in different fisheries, brood years 1989-2011; NP = no hatchery program.

${ }^{\text {a }}$ Includes the Wanapum fishery and the Icicle and Wenatchee fisheries when they occurred.

## Straying

Stray rates were determined by examining CWTs recovered on spawning grounds within and outside the Wenatchee River basin. Targets for strays based on return year (recovery year) within the Wenatchee River basin should be less than $10 \%$ and targets for strays outside the Wenatchee River basin should be less than $5 \%$. The target for brood year stray rates should be less than $5 \%$.
The percentage of the spawning escapement made up of hatchery-origin Chiwawa spring Chinook in non-target spawning areas within the Wenatchee River basin has been high in some years and exceeded the target of $10 \%$ (Table 5.36). Over the years of sampling, Chiwawa spring Chinook have strayed into all non-target spawning areas, but, on average, have contributed most to the Nason Creek and Upper Wenatchee spawning escapements.

Table 5.36. Number (No.) and percent (\%) of the spawning escapement in other non-target spawning streams within the Wenatchee River basin that consisted of hatchery-origin Chiwawa spring Chinook, return years 1992-2015. For example, for return year 2001, 35.3\% of the spring Chinook spawning escapement in Nason Creek consisted of hatchery-origin Chiwawa spring Chinook. Percent strays should be less than $10 \%$.

Hatchery-origin Chiwawa spring Chinook have strayed into the Methow and Entiat basins (Table 5.37). Based on return year analyses, rates of hatchery-origin Chiwawa spring Chinook straying into these populations have been low in most years; in 2015, Chiwawa spring Chinook made up 4.7\% of the spawning escapement in the Entiat River and $0.5 \%$ in the Methow River. However, during return years 2002, 2006, 2008-2009, and 2011-2013, Chiwawa spring Chinook made up more than $5 \%$ of the spawning escapement in the Entiat River basin. In three years, Chiwawa spring Chinook hatchery fish made up more than $20 \%$ of the spawning escapement in the Entiat River basin; however, in return year 2014, no strays were detected in the Entiat or Methow River basins.

Table 5.37. Number and percent of spawning escapements within other non-target basins that consisted of hatchery-origin Chiwawa spring Chinook, return years 1992-2015. For example, for return year 2002, $9.2 \%$ of the spring Chinook spawning escapement in the Entiat River basin consisted of hatchery-origin Chiwawa spring Chinook. Percent strays should be less than 5\%. NS = not sampled.

Based on brood year analyses, on average, about $30 \%$ of the hatchery returns have strayed into non-target spawning areas, exceeding the target of $5 \%$ (Table 5.38). Depending on brood year, percent strays into non-target spawning areas have ranged from $0-81 \%$. In most years, few ( $<1 \%$ ) have strayed into non-target hatchery programs.

Table 5.38. Number and percent of hatchery-origin Chiwawa spring Chinook that homed to target spawning areas and the target hatchery program, and number and percent that strayed to non-target spawning areas and non-target hatchery programs, by brood years 1989-2011. Percent strays should be less than 5\%.

* Homing to the target hatchery includes Chiwawa hatchery spring Chinook that are captured and included as broodstock in the Chiwawa Hatchery program. These hatchery fish are typically collected at the Chiwawa weir and Tumwater Dam.
Ford et al. (2015) used parentage analysis to estimate rates of straying and homing of spring Chinook within the Wenatchee River basin. They found that stray rates of hatchery spring Chinook based on parentage analysis were consistent with rates estimated using physical tag recoveries (the latter estimates are shown in the tables above). They also found that stray rates among the major spawning tributaries were higher than stray rates of tagged fish to areas outside of the Wenatchee River basin (e.g., Entiat and Methow basins), which is consistent with the results shown in the
tables above. Finally, the researchers noted that hatchery spring Chinook homed at a far lower rate than natural-origin fish and stray rates of natural-origin fish ranged from about $0-100 \%$. Rates of straying of natural-origin spring Chinook were affected by spawning tributary and by parental origin (i.e., progeny of naturally spawning hatchery-produced fish strayed at higher rates than progeny whose parents were of natural origin).

## Genetics

Genetic studies were conducted in 2007 to determine the potential effects of the Chiwawa Supplementation Program on natural-origin spring Chinook in the upper Wenatchee River basin (Blankenship et al. 2007; the entire report is appended as Appendix K). A total of 32 population collections of adult spring Chinook were obtained from the Wenatchee River basin between 1989 and 2006. This included nine collections of natural-origin Chinook adults from the Chiwawa River $(\mathrm{N}=501)$ and nine collections of Chiwawa hatchery-origin Chinook $(\mathrm{N}=595)$ at the Chiwawa weir. Collections in 1993 and 1994 included hatchery-origin smolts. Additional samples were collected from the White River, Little Wenatchee River, and Nason Creek; six collections of natural-origin Chinook from the White River ( $\mathrm{N}=179$ ), one collection from the Little Wenatchee ( $\mathrm{N}=19$ ), and six collections from Nason Creek $(\mathrm{N}=268)$. A single collection was obtained for Chinook spawning in the mainstem Wenatchee River and from the Leavenworth National Fish Hatchery. Finally, an out-of-basin collection from the Entiat River was included in the analysis. Scale, fin clips, or operculum punches were collected from each sample. Microsatellite DNA allele frequencies were used to statistically assign individual fish to specific demes (locations) within the Wenatchee population. In addition, genetic effects of the hatchery program were assessed by examining relationships between census and effective population sizes ( $\mathrm{N}_{\mathrm{e}}$ ) from samples collected before and after supplementation.

Overall, this work showed that although allele frequencies within and between natural and hatchery-origin spring Chinook were significantly different, there was no evidence (i.e., robust signal) that the difference was the result of the hatchery program. Rather, the differences were more likely the result of life history characteristics. However, there was an increasing trend toward homogenization of the allele frequencies of the natural and hatchery-origin fish that comprised the broodstock, even though there was consistent year-to-year variation in allele frequencies among hatchery and natural-origin fish. In addition, there were no robust signals indicating that hatcheryorigin hatchery broodstock, hatchery-origin natural spawners, natural-origin hatchery broodstock, and natural-origin natural spawners were substantially different from each other. Finally, the $\mathrm{N}_{\mathrm{e}}$ estimate of 387 was only slightly larger than the pre-hatchery $\mathrm{N}_{\mathrm{e}}$ (based on demographic data from 1989-1992), which means that the Chiwawa hatchery program has not reduced the $\mathrm{N}_{\mathrm{e}}$ of the Wenatchee spring Chinook population.
Significant differences in allele frequencies were observed within and among major spawning areas in the Upper Wenatchee River basin. However, these differences made up only a very small portion of the overall variation, indicating genetic similarity among the major spawning areas. There was no evidence that the Chiwawa program has changed the genetic structure (allele frequency) of spring Chinook in Nason Creek and the White River, despite the presence of hatchery-origin spawners in both systems.

It is important to note that no new information will be reported on genetics until the next five-year report (2018).

## Proportionate Natural Influence

Another method for assessing the genetic risk of a supplementation program is to determine the influence of the hatchery and natural environments on the adaptation of the composite population. This is estimated by the proportion of natural-origin fish in the hatchery broodstock ( pNOB ) and the proportion of hatchery-origin fish in the natural spawning escapement ( pHOS ). We calculated Proportionate Natural Influence (PNI) by iterating Ford's (2002) equations 5 and 6 to equilibrium, using a heritability of 0.3 and a selection strength of three standard deviations. ${ }^{14}$ The larger the PNI value, the greater the strength of selection in the natural environment relative to that of the hatchery environment. For the natural environment to dominate selection, PNI should be greater than 0.50 , and important integrated populations should have a PNI of at least 0.67 (HSRG/WDFW/NWIFC 2004).

For brood years 1989-1994, PNI values were greater than or equal to 0.67 (Table 5.39). Since brood year 1994, PNI has been less than 0.67 , except for brood year 2016, which was 0.70 .
Table 5.39. Proportionate Natural Influence (PNI) values for the Chiwawa spring Chinook supplementation program for brood years 1989-2016. NOS = number of natural-origin Chinook on the spawning grounds; HOS = number of hatchery-origin Chinook on the spawning grounds; NOB $=$ number of natural-origin Chinook collected for broodstock; and $\mathrm{HOB}=$ number of hatchery-origin Chinook included in hatchery broodstock.

${ }^{\text {a }}$ PNI was calculated previously using PNI approximate equation 11 (HSRG 2009; their Appendix A). All PNI values presented here were recalculated by iterating Ford's (2002) equations 5 and 6 to equilibrium using a heritability of 0.3 and a selection strength of three standard deviations. C. Busack, NOAA Fisheries, 21 March 2016, provided the model for calculating PNI.

## Post-Release Survival and Travel Time

We used PIT-tagged fish to estimate survival rates and travel time (arithmetic mean days) of hatchery spring Chinook from the Chiwawa River release site to McNary Dam, and smolt to adult ratios (SARs) from release to detection at Bonneville Dam (Table 5.40). ${ }^{15}$ Over the ten brood years for which PIT-tagged hatchery fish were released, survival rates from the Chiwawa River to McNary Dam ranged from 0.435 to 0.662 ; SARs from release to detection at Bonneville Dam ranged from 0.003 to 0.018 . Average travel time from the Chiwawa River to McNary Dam ranged from 14 to 44 days. Although there is only one year in which a forced release was compared to a volitional release (brood year 2005), hatchery spring Chinook that were forced out of the Chiwawa Acclimation Facility had slightly higher survival rates and SARs, and a faster travel time to McNary Dam, than did the volitional release.
Table 5.40. Total number of Chiwawa hatchery spring Chinook released with PIT tags, their survival and travel times (mean days) to McNary Dam, and smolt-to-adult (SAR) ratios for brood years 2005-2014. Standard errors are shown in parentheses. NA = not available (i.e., not all the adults from the release groups have returned to the Columbia River).

## Natural and Hatchery Replacement Rates

Natural replacement rates (NRR) were calculated as the ratio of natural-origin recruits (NOR) to the parent spawning population (spawning escapement). Natural-origin recruits are naturally produced (wild) fish that survive to contribute to harvest (directly or indirectly), to broodstock, and to spawning grounds. We do not account for fish that died in route to the spawning grounds (migration mortality) or died just before spawning (pre-spawn mortality) (see Appendix B in Hillman et al. 2012). We calculated NORs with and without harvest. NORs without harvest include all returning fish that either returned to the basin or were collected as wild broodstock. NORs with harvest include all fish harvested and are based on a brood year harvest rates from the hatchery program. For brood years 1989-2010, NRR for spring Chinook in the Chiwawa averaged 1.05 (range, 0.01-4.40) if harvested fish were not included in the estimate and 1.16 (range, 0.01-4.81) if harvested fish were included in the estimate (Table 5.41). NRRs for more recent brood years will be calculated as soon as all tag recoveries and sampling rates have been loaded into the database.
Hatchery replacement rates (HRR) are the hatchery adult-to-adult returns and were calculated as the ratio of hatchery-origin recruits (HOR) to the parent broodstock collected. These rates should be greater than the NRRs and greater than or equal to 6.7 (the calculated target value in Hillman et al. 2013). The target value of 6.7 includes harvest. In nearly all years, HRRs were greater than NRRs, regardless if harvest was or was not included (Table 5.41). HRRs exceeded the estimated target value of 6.7 in 9 of the 20 years.
Table 5.41. Broodstock collected, spawning escapements, natural and hatchery-origin recruits (NOR and HOR), and natural and hatchery replacement rates (NRR and HRR; with and without harvest) for spring Chinook in the Chiwawa River basin, brood years 1989-2010; NP = no hatchery program.

## Smolt-to-Adult Survivals

Smolt-to-adult survival ratios (SARs) were calculated as the number of hatchery adult recaptures divided by the number of tagged hatchery smolts released. Here, SARs were based on CWT returns. For the available brood years, SARs have ranged from 0.00036 to 0.01563 for hatchery spring Chinook (Table 5.42).

Table 5.42. Smolt-to-adult ratios (SARs) for Chiwawa hatchery spring Chinook, brood years 1989-2011.

| Brood year | Number of tagged smolts released ${ }^{\text {a }}$ | Estimated adult captures ${ }^{\text {b }}$ | SAR |
| :---: | :---: | :---: | :---: |

${ }^{\text {a }}$ Includes all tag codes and CWT released fish (CWT + Ad Clip fish and CWT-only fish).
${ }^{\mathrm{b}}$ Includes estimated recoveries (spawning ground, hatcheries, harvest, etc.) and observed recoveries if estimated recoveries were unavailable.

### 5.8 ESA/HCP Compliance

## Broodstock Collection

The collection of 2014 Brood Chiwawa River spring Chinook broodstock was consistent with the 2014 Upper Columbia River salmon and steelhead broodstock objectives and site-based broodstock collection protocols. Specifically, broodstock collection targeted previously PITtagged natural-origin fish at Tumwater Dam and operation of the Chiwawa Weir. In-season adjustments were made to the natural-origin spring Chinook collected for broodstock as needed and were based on in-season escapement monitoring at Tumwater Dam and estimated Chiwawa run-escapement.

Trapping at Tumwater Dam began on 8 June 2014 and concluded on 14 July 2014. Operation of the Chiwawa Weir was limited to 15 days between 1 June and 15 August and was further constrained by flows and total available bull trout effects. Broodstock collection targeted naturalorigin spring Chinook and hatchery-origin spring Chinook as needed to attain a $100 \%$ naturalorigin broodstock and a maximum $33 \%$ extraction of the estimated natural-origin return to the Chiwawa River.

The 2014 brood collection retained a total of 61 natural-origin spring Chinook. All spring Chinook, steelhead, and bull trout that were captured were anesthetized with tricaine methanesulfonate (MS222) and subject to water-to-water transfers during handling. All fish were allowed to fully recover before release.

The estimated broodstock extraction rate of natural-origin Chiwawa spring Chinook and overall extraction of spring Chinook upstream from Tumwater Dam comply with provisions of ESA Permit 18121.

## Hatchery Rearing and Release

The rearing and release of 2014 brood Chiwawa spring Chinook was completed without incident. No mortality events occurred that exceeded $10 \%$ of the population. Fish were acclimated on Chiwawa River water with regulated amounts of Wenatchee River water to prevent frazzle ice formation during the winter months (see Section 5.2).

The release of 2014 brood Chiwawa spring Chinook smolts totaled 144,360 fish, representing $100 \%$ of the program objective of 144,023 smolts and complied with the ESA Section 10 Permit 18121 program not to exceed the level of 158,425 smolts.

## Hatchery Effluent Monitoring

Per ESA Permits 1196 (expired), 1347 (expired), 1395 (expired), 18118, 18120, and 18121, permit holders shall monitor and report hatchery effluents in compliance with applicable National Pollution Discharge Elimination Systems (NPDES) (EPA 1999) permit limitations. There were no NPDES violations reported at the Chelan PUD Hatchery facilities during the period 1 January through 31 December 2016. NPDES monitoring and reporting for Chelan PUD Hatchery Programs during 2016 are provided in Appendix F.

## Smolt and Emigrant Trapping

Per ESA Section 10 Permit Nos. 18118, 18120, and 18121, the permit holders are authorized a direct take of up to $20 \%$ of the emigrating spring Chinook population during juvenile emigration monitoring and a lethal take not to exceed $2 \%$ of the fish captured (NMFS 2013). Based on the estimated wild spring Chinook population (smolt trap expansion) and hatchery juvenile spring Chinook population estimate (hatchery release data) for the Wenatchee River basin, the reported spring Chinook encounters during 2016 emigration monitoring complied with take provisions in the Section 10 permit. Spring Chinook encounter and mortality rates for each trap site (including PIT tag mortalities) are detailed in Table 5.43. Additionally, juvenile fish captured at the trap locations were handled consistent with provisions in ESA Section 10 Permits 18118, 18120, and 18121, Section B.

Table 5.43. Estimated take of Upper Columbia River spring Chinook resulting from juvenile emigration monitoring in the Wenatchee River basin, 2016.

| Trap location | Population estimate |  |  | Number trapped |  |  | Total | Take allowed under Permit |

${ }^{c}$ Based on size, date of capture and location of capture, subyearling Chinook encountered at the Lower Wenatchee Trap are categorized as summer Chinook salmon.
${ }^{\mathrm{d}}$ Combined trapping and PIT tagging mortality.

## Spawning Surveys

Spring Chinook spawning ground surveys were conducted in the Wenatchee River basin during 2016, as authorized by ESA Section 10 Permits 18118, 18120, and 18121. Because of the difficulty of quantifying the level of take associated with spawning ground surveys, the Permit does not specify a take level associated with these activities, even though it does authorize implementation of spawning ground surveys. Therefore, no take levels are reported. However, to minimize potential effects to established redds, wading was restricted to the extent practical, and extreme caution was used to avoid established redds when wading was required.

## Spring Chinook Reproductive Success Study

ESA Section 10 Permits 18118,18120 , and 18121 specifically provide authorization to capture, anesthetize, biologically sample, PIT tag, and release adult spring Chinook at Tumwater Dam for reproductive success studies and general program monitoring. During 2010 through 2016, all spring Chinook passing Tumwater Dam were enumerated, anesthetize, biologically sampled, PIT tagged, and released (not including hatchery-origin Chinook retained for broodstock) as a component of the reproductive success study (BPA Project No. 2003-039-00). Please refer to Ford et al. $(2010,2011,2012,2013,2014,2015$, and 2016) for complete details on the methods and results of the spring Chinook reproductive success study for the period 2010-2016.

## SECTION 6: NASON CREEK SPRING CHINOOK

The goals of the Nason Creek spring Chinook salmon supplementation program are to conserve, aid in the recovery, and prevent the extinction of naturally spawning spring Chinook in Nason Creek, and to meet the mitigation responsibilities of Grant County PUD. In 1997, a spring Chinook captive-broodstock program was initiated for the Nason Creek population to reduce the risk of extinction. Improvements in adult escapement in Nason Creek have reduced the near-term risk of extinction and therefore the captive-broodstock program was discontinued. An adult-based supplementation program began with the collection of broodstock in 2013. The first releases of the program occurred from the Nason Creek Acclimation Facility in the spring of 2015.
In 2013, natural-origin adult spring Chinook were collected for broodstock at Tumwater Dam and from Nason Creek using tangle and dip nets. In 2014, all natural-origin broodstock were collected from Nason Creek using tangle and dip nets. While these brood collection methods were successful at collecting adults from the Nason Creek spawning aggregate, they were unable to collect the necessary number of adults to meet mitigation production goals in 2013 and 2014. The PRCC Hatchery Subcommittee decided to implement the Nason Creek conservation program using a composite of Nason and Chiwawa natural-origin broodstock beginning with brood year 2015 in order to be able to consistently meet program goals. The decision was also made to collect all the brood at Tumwater Dam.
The production goal for the Nason Creek program requires collection of 126 adult spring Chinook (64 natural-origin fish and 66 hatchery-origin fish). However, the Section 10 permit requirements restrict the number of natural-origin adults collected and cannot exceed $33 \%$ of the natural-origin spring Chinook estimates to Tumwater Dam.
Adult spring Chinook broodstock are spawned and reared at Eastbank Fish Hatchery. Juvenile spring Chinook are transferred from the hatchery to the Nason Creek Acclimation Facility in late September or early October. Fish are reared in 30-foot dual-drain circular tanks throughout winter at the Nason Creek Acclimation Facility. Yearling Chinook were released volitionally during April and May the following year up until 2015. Beginning in 2016, all fish are force released at night to improve survival.
The current production goal is to release 223,670 smolts ( 125,000 for conservation and 98,670 for safety net). Juveniles released from the Nason facility will be $100 \%$ marked with CWTs and a minimum of 5,000 fish will be PIT tagged annually.
The following information focuses on results from monitoring the Nason Creek spring Chinook program. Information on spring Chinook collected throughout the Wenatchee River basin is presented in Section 5.

### 6.1 Broodstock Sampling

This section focuses on results from sampling 2014-2016 Nason Creek spring Chinook broodstock, which were collected in Nason Creek in 2014 and at Tumwater Dam in 2015 and 2016.

## Origin of Broodstock

Natural-origin adults made up between $48 \%$ and $100 \%$ of the Nason Creek spring Chinook broodstock for return years 2014-2016 (Table 6.1). Beginning with brood year 2015, natural-origin adults were targeted for collection at Tumwater Dam during trapping operations. Natural-origin fish collected at Tumwater Dam were used for broodstock if genotyping confirmed they were natural-origin fish from the Wenatchee population and they were not White River fish. Fish that were genotyped to the White River were returned to the upper Wenatchee River basin to spawn naturally.

Table 6.1. Numbers of wild and hatchery Nason Creek spring Chinook collected for broodstock, numbers that died before spawning, and numbers of Chinook spawned, 2013-2016. Unknown origin fish (i.e., undetermined by scale analysis, no CWT or fin clips, and no additional hatchery marks) were considered naturally produced. Mortality includes fish that died of natural causes typically near the end of spawning and were not needed for the program or were surplus fish killed at spawning.

| Brood year | Wild spring Chinook |  |  |  |  | Hatchery spring Chinook |  |  |  |  | Total number spawned |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Number collected | Prespawn loss $^{\mathbf{a}}$ loss $^{\text {a }}$ | Mortality | Number spawned spawned | Number released | Number collected | Prespawn loss $^{\text {a }}$ | Mortality | Number spawned | Number released |  |
| 2013 | 22 | 0 | 1 | 21 | 0 | 4 | 0 | 0 | 4 | 0 | 25 |
| $2014{ }^{\text {b }}$ | 28 | 2 | 5 | 21 | 0 | 0 | 0 | 0 | 0 | 0 | 21 |
| 2015 | 78 | 1 | 6 | 59 | 12 | 63 | 0 | 0 | 63 | 0 | 122 |
| 2016 | 82 | 0 | 1 | 70 | 11 | 68 | 1 | 1 | 66 | 0 | 136 |
| Average $^{\text {c }}$ | 53 | 1 | 3 | 43 | 6 | 34 | 0 | 0 | 33 | 0 | 76 |
| Median ${ }^{\text {c }}$ | 53 | 1 | 3 | 40 | 6 | 34 | 0 | 0 | 34 | 0 | 74 |

${ }^{\text {a }}$ Pre-spawn loss represents the number of fish that died during the holding period before spawning. Mortality is the number of fish that were surplused following spawning.
${ }^{\text {b }}$ Until sufficient Nason Creek Spring Chinook HOR's are collected to meet broodstock objectives, Chiwawa Spring Chinook HOR's are utilized to fulfill program goals (see table 5.1 and the 2014 Broodstock Protocols). About 12 Chiwawa HORs were used to fulfill the Chiwawa Program; about 122 Chiwawa HORs were used to fulfill the Nason Creek safety-net obligation.
${ }^{\mathrm{c}}$ Origin determinations should be considered preliminary pending scale analyses.

## Age/Length Data

Ages were determined from scales and/or coded wire tags (CWT) collected from broodstock. For both the 2015 and 2016 returns, most adults, regardless of origin, were age-4 Chinook (Table 6.2). A larger percentage of the age- 3 and 5 Chinook were natural-origin fish.
Table 6.2. Percent of hatchery and wild spring Chinook of different ages (total age) collected from broodstock, 2013-2016.

| Return year | Origin | Total age |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |

${ }^{\text {a }}$ Data from Table 5.3.

## Sex Ratios

Male spring Chinook in the 2014-2016 return years made up $60 \%, 50 \%$, and $49 \%$, respectively, of the adults collected. This resulted in overall male to female ratios of 1.50:1.00, 1.01:1.00, and $0.95: 1.00$, respectively (Table 6.4).
Table 6.4. Numbers of male and female wild and hatchery spring Chinook collected for broodstock, 20132016. Ratios of males to females are also provided.

| Return <br> year | Number of wild spring Chinook |  |  | Number of hatchery spring Chinook |  |  | Total M/F <br> ratio |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Males (M) | Females (F) | $\mathbf{M} / \mathbf{F}$ | Males (M) | Females (F) | M/F |  |
| 2013 | 12 | 10 | $1.20: 1: 00$ | 1 | 3 | $0.33: 1.00$ | - |
| $2014^{\mathrm{a}}$ | 18 | 12 | $1.50: 1.00$ | 0 | 0 | $1.50: 1.00$ |  |
| 2015 | 40 | 38 | $1.05: 1.00$ | 31 | 32 | $0.97: 1.00$ | $1.01: 1.00$ |
| 2016 | 40 | 42 | $0.95: 1.00$ | 33 | 35 | $0.94: 1.00$ | $0.95: 1.00$ |
| Total | $\mathbf{1 1 0}$ | $\mathbf{1 0 2}$ | $\mathbf{1 . 0 8 : 1 . 0 0}$ | $\mathbf{6 5}$ | $\mathbf{7 0}$ | $\mathbf{0 . 9 3 : 1 . 0 0}$ | $\mathbf{1 . 0 2 : 1 . 0 0}$ |

${ }^{\mathrm{a}}$ Data for HOR brood are in Table 5.4.

## Fecundity

The mean fecundities for the 2014-2016 returns of Nason Creek spring Chinook ranged from 3,787-4,487 eggs per female (Table 6.5). Fecundities in the 2013 and 2015 natural-origin brood, and in the 2013, 2014, and 2016 hatchery-origin brood were less than the expected fecundity of 4,400 eggs per female assumed in the broodstock protocol.
Table 6.5. Mean fecundity of wild, hatchery, and all female spring Chinook collected for broodstock, 20132016.

| Return year | Mean fecundity |  |  |
| :---: | :---: | :---: | :---: |
|  | Wild | Hatchery | Total |
| 2013 | 4,047 | 4,069 | 4,052 |
| $2014^{\mathrm{a}}$ | 4,484 | 3,834 | 3,787 |
| 2015 | 4,380 | 4,535 | 4,463 |
| 2016 | 4,688 | 4,274 | 4,487 |
| Average | $\mathbf{4 , 4 0 0}$ | $\mathbf{4 , 1 7 8}$ | $\mathbf{4 , 1 9 7}$ |

${ }^{a}$ Average fecundities are from Table 5.5.

### 6.2 Hatchery Rearing

## Rearing History

## Number of eggs taken

Based on the unfertilized egg-to-release survival standard of $85 \%$, a total of 263,141 eggs are required to meet the program release goal of 223,670 smolts (Table 6.6). The green egg take for the 2014-2016 brood years was $102 \%, 102 \%$, and $119 \%$ of program goal, respectively.
Table 6.6. Numbers of eggs taken from spring Chinook broodstock, 2013-2016.

| Return year | Number of eggs taken |
| :---: | :---: |
| $2013^{\mathrm{a}}$ | 49,720 |
| $2014^{\mathrm{b}}$ | 267,783 |
| 2015 | 268,247 |
| 2016 | 314,090 |
| Average | $\mathbf{2 2 4 , 9 6 0}$ |
| Median | $\mathbf{2 6 8 , 0 1 5}$ |

${ }^{\text {a }}$ Safety-net obligation met through the White River Program. Conservation egg take goal was 116,082.
${ }^{\mathrm{b}}$ Includes surrogate Chiwawa HxH egg take calculated from tagging proportions.

## Number of acclimation days

Fish from the 2014 brood were acclimated for 119-166 days on Nason Creek water and 12 days on well water with oxygen (Table 6.7).

Table 6.7. Number of days spring Chinook broods were acclimated on Nason Creek water and well water, brood years 2013-2014.

| Brood year | Release year | Transfer date | Release date | Number of acclimation <br> days |
| :---: | :---: | :---: | :---: | :---: |
| 2013 | 2015 | 13 Oct | $13 \mathrm{Apr}-1 \mathrm{May}$ | $182-200$ |
| $2014^{\mathrm{a}}$ | 2016 | $21-23$ Oct | $15-20 \mathrm{Apr}$ | $119-122$ Nason, 12 Well |

${ }^{\text {a }}$ Because of water-intake concerns at the Nason Creek Acclimation Facility, the HxH Chinook were transferred to the Chiwawa Acclimation Facility on 2-3 March for final acclimation and release. The WxW fish were on Nason Creek water for 166 days. The HxH fish were on Nason Creek water for 119-122 days and on Chiwawa River water for 43-49 days. WxW and HxH fish were on well water and oxygen for 12 days while rearing at the Nason Creek Acclimation Facility.

## Release Information

## Numbers released

The 2014 brood Nason Creek spring Chinook program achieved $25.8 \%$ of the 125,000 target goal with about $32,215 \mathrm{WxW}$ smolts forced into Nason Creek in 2016 (Table 6.8). The remainder of the smolt obligation was fulfilled with HxH progeny. The HxH Nason program was transferred to the Chiwawa Acclimation Facility on 2-3 March 2016 for final acclimation because of waterintake concerns at the Nason Creek Acclimation Facility (see Table 5.8). A total of 196,866 HxH smolts were released from the Chiwawa Acclimation Facility for the Nason spring Chinook program.
Table 6.8. Numbers of spring Chinook smolts tagged and released from the hatchery, brood years 20132014. The release target for Nason Creek spring Chinook is 125,000 smolts.

| Brood year | Release year | Type of <br> release | CWT mark <br> rate | Number <br> released that <br> were PIT <br> tagged | Number of <br> smolts <br> released | Total number <br> of smolts <br> released |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 2013 | 2015 | Volitional | 0.9303 | 20,139 | 43,082 | 43,082 |
| $2014^{\mathrm{a}}$ | 2016 | Forced | 0.9650 | 5,009 | 32,215 | 32,215 |

${ }^{\text {a }}$ Only the WxW Nason program was released from the Nason Creek Acclimation Facility because of water-intake concerns. The HxH Nason program was transferred to the Chiwawa Acclimation Facility on 2-3 March 2016 (see Table 5.8).

## Numbers tagged

The 2014 brood Nason spring Chinook were $96 \%$ CWT and blank CWT adipose tagged (Table 6.8).

In 2017, a total of 10,104 Nason Creek spring Chinook from the 2015 brood were tagged at the Nason Creek Acclimation Facility on 6-9 March. Chinook in Ponds 1, 3, 5, and 7 were HxH fish, while Chinook in Ponds 2, 4, 6, and 8 were WxW fish. Fish were not fed during tagging or for two days before and after tagging. Fish averaged $110-115 \mathrm{~mm}$ in length and 17-19 g at time of tagging.
Table 6.9 summarizes the number of hatchery spring Chinook that have been PIT-tagged and released into Nason Creek.

Table 6.9. Summary of PIT-tagging activities for Nason Creek hatchery spring Chinook, brood years 20132014.

| Brood year | Release year | Number of fish <br> tagged | Number of <br> tagged fish that <br> died | Number of tags <br> shed | Number of <br> tagged fish <br> released |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 2013 | 2015 | 20,234 | 94 | 1 | 20,139 |
| 2014 | 2016 | 5,010 | 1 | 0 | 5,009 |

## Fish size and condition at release

The WxW spring Chinook from the 2014 brood were released as yearling smolts from 15-20 April 2016. Size at release ( 21 fpp ) was larger than the approximate target of 24 fpp established for the program. The CV for fork length was just short of the target (Table 6.10).

The HxH spring Chinook were transferred to the Chiwawa Acclimation Facility for final rearing on 2-3 March 2016 because of water-intake concerns at the Nason Creek Acclimation Facility. These fish were volitionally released as yearling smolts from 15-20 April 2016 into the Chiwawa River. Size at release ( 16 fpp ) was larger than the approximate target of 18 fpp established for the Chiwawa program. The CV for fork length was just short of the target (see Table 5.10).

Table 6.10. Mean lengths (FL, mm), weight (g and fish/pound), and coefficient of variation (CV) of spring Chinook smolts released from the hatchery, brood years 2013-2014. Size targets are provided in the last row of the table.

| Brood year | Release year | Fork length (mm) |  | Mean weight |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Mean | CV | Grams (g) | Fish/pound |

| Average |  | 127 | 8 | 24.7 | 19 |
| Median |  | 127 | 8 | 24.7 | 19 |
| Targets |  | 155 | 9.0 | 37.8 | 18 |

${ }^{\text {a }}$ This represents only the WxW Nason program released from the Nason Creek Acclimation Facility. The HxH program was transferred to the Chiwawa Acclimation Facility on 2-3 March 2016 for release because of water-intake concerns at the Nason Creek Acclimation Facility. Statistics on the 2014 brood HxH program pre-release sample at the Chiwawa Acclimation Facility were 134 mean length, 17.5 length CV, 28.6 g mean wt., and 16 fpp .

## Survival Estimates

Overall survival of Nason Creek spring Chinook from green (unfertilized) egg to release was above the standard set for the program (Table 6.11). There was higher than expected survivals throughout all stages contributing to increased program performance. Pre-spawn survival of adults was also above the standard set for the program.

Table 6.11. Hatchery life-stage survival rates (\%) for spring Chinook, brood years 2013-2014. Survival standards or targets are provided in the last row of the table.

| Brood <br> year | Collection to <br> spawning |  | Unfertilized <br> egg-eyed | Eyed <br> egg- <br> ponding | $\mathbf{3 0 d}$ <br> after <br> ponding | $\mathbf{1 0 0 ~ d}$ <br> after <br> ponding | Ponding <br> to <br> release | Transport <br> to release | Unfertilized <br> egg-release |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 100.0 | 100.0 |  | 98.8 | 99.4 | 98.2 | 93.8 | 99.1 | 86.6 |
| $2014^{\mathrm{a}}$ | 97.3 | 100.0 | 91.3 | 97.6 | 99.5 | 99.0 | 98.1 | 99.5 | 87.4 |
| Average | 98.7 | 100.0 | 92.4 | 98.2 | 99.5 | 98.6 | 96.0 | 99.3 | 87.0 |
| Median | 98.7 | 100.0 | 92.4 | 98.2 | 99.5 | 98.6 | 96.0 | 99.3 | 87.0 |
| Standard | 90.0 | 85.0 | 92.0 | 98.0 | 97.0 | 93.0 | 90.0 | 95.0 | 81.0 |

${ }^{\text {a }}$ The survival estimates are a combination of the WxW and HxH Nason programs. The WxW program was reared at the Nason Creek Acclimation Facility until release. The HxH Chinook that were reared at the Nason Creek Acclimation Facility until transferred to the Chiwawa Acclimation Facility on 2-3 March 2016 because of water-intake concerns at the Nason Creek Acclimation Facility. The HxH fish were released from the Chiwawa Acclimation Facility on 15-20 April 2016.

### 6.3 Disease Monitoring

Results of 2016 adult broodstock bacterial kidney disease (BKD) monitoring indicated that most females ( $90 \%$ ) had ELISA values less than 0.199 . Ten percent of the females had ELISA values greater than 0.120, resulting in no limitations to rearing densities (Table 6.12).
For the 2014 brood, a formalin drip treatment was used shortly after transfer to the Nason Creek Acclimation Facility to prevent infection associated with stress caused by the transfer. No significant health issues were encountered for the remainder of juvenile rearing.
Table 6.12. Proportion of bacterial kidney disease (BKD) titer groups for the Nason Creek spring Chinook broodstock by origin, brood years 2013-2016. Also included are the proportions to be reared at either 0.125 fish per pound or 0.060 fish per pound.

${ }^{\text {a }}$ Determination of origin should be considered preliminary pending scale analyses.
${ }^{\mathrm{b}}$ ELISA values from broodstock BKD testing dictate what density the progeny of the broodstock are reared. Progeny of broodstock with high ELISA values are reared at lower density.

### 6.4 Natural Juvenile Productivity

During 2016, juvenile spring Chinook were sampled at the Nason Creek trap.

## Smolt and Emigrant Estimates

Numbers of spring Chinook smolts and emigrants were estimated at the Nason Creek trap in 2016. A complete description of trapping operations on Nason Creek can be found in Appendix L.

## Nason Creek Trap

The Nason Creek Trap operated between 1 March and 30 November 2016. During that time, the trap was inoperable for 62 days because of low stream discharge or flooding. Daily trap efficiencies were estimated from a flow-efficiency regression model. The daily number of fish captured was expanded by the estimated trap efficiency to estimate total emigration. If a viable flow-efficiency regression could not be developed, a pooled efficiency was used to expand daily catch. All pooled estimates will be recalculated as flow-efficiency models are developed.
Wild yearling spring Chinook (2014 brood year) were captured primarily from March through April 2016 (Figure 6.1). Because a viable yearling emigrant flow-efficiency regression model could not be established at the downstream trap location, a pooled estimate was employed as a temporary method of expansion. Based on this pooled efficiency, the total number of wild yearling Chinook from the Nason Creek basin was $930( \pm 5,083)$. Combining the number of subyearling spring Chinook $(2,851)$ that emigrated during the fall of 2015 with the total number of yearling Chinook (930) that emigrated during 2016 resulted in an emigrant estimate of $3,781( \pm 5,102)$ spring Chinook (Table 6.13). Based on PIT-tag analysis, an additional 29 ( $\pm 37$ ) spring Chinook immigrated during the winter (1 December - 28 February) when the trap was inoperable. Thus, the total number of emigrants was $3,810( \pm 5,126)$ spring Chinook for the 2014 brood year.

## Juvenile Spring Chinook

Figure 6.1. Monthly captures of wild subyearling and wild and hatchery yearling spring Chinook at the Nason Creek Trap, 2016.

${ }^{\text {a }}$ Egg deposition is calculated as the number of redds times the fecundity of both wild and hatchery spring Chinook salmon (from Table 5.5.
${ }^{\mathrm{b}}$ Subyearling emigrants does not include fry that left the watershed before 1 July.
${ }^{\text {c }}$ Brood years 2002-2012 do not include estimates of numbers of juvenile spring Chinook that emigrated during non-trapping periods ( 1 Dec to 28 Feb ). Brood years 2013 to present include estimates of numbers of juvenile spring Chinook that emigrated during non-trapping periods.

Wild subyearling spring Chinook (2015 brood year) were captured between 10 March and 29 November 2016 (Figure 6.1). Based on capture efficiencies estimated from the flow model, the total number of wild subyearling Chinook emigrating from Nason Creek was 5,540 ( $\pm 997$ ).
Yearling spring Chinook sampled in 2016 averaged 96 mm in length, 9.0 g in weight, and had a mean condition of 1.01 (Table 6.14). Estimated length and weight for these fish were greater than the overall mean of yearling spring Chinook sampled in previous years (overall means, 93 mm and 8.5 g ), while the estimated condition was less (overall mean, 1.05). Subyearling spring Chinook sampled in 2016 at the Nason Creek Trap averaged 85 mm in length, 6.9 g in weight, and had a mean condition of 1.07 (Table 6.14). These size estimates were greater than the overall mean of subyearling spring Chinook sampled in previous years (overall means, $77 \mathrm{~mm}, 5.1 \mathrm{~g}$, and condition of 1.07).

Table 6.14. Mean fork length (mm), weight (g), and condition factor of subyearling and yearling spring Chinook collected in the Nason Creek Trap, 2004-2016. Numbers in parentheses indicate 1 standard deviation.

${ }^{\text {a }}$ Sample size represents the number of fish that were measured for both length and weight.

## Freshwater Productivity

Both productivity and survival estimates for different life stages of spring Chinook in the Nason Creek watershed are provided in Table 6.15. Estimates for brood year 2014 were generally lower than estimates for brood years 2002-2013. During the period 2002-2014, freshwater productivities
ranged from 8-77 smolts/redd and 33-271 emigrants/redd. Survivals during the same period ranged from 0.2-1.3\% for egg-smolt and 0.9-5.8\% for egg-emigrants.
Table 6.15. Productivity (fish/redd) and survival (\%) estimates for different juvenile life stages of spring Chinook in the Nason Creek watershed for brood years 2002-2014; ND = no data. These estimates were derived from data in Table 6.13.

| Brood year | Smolts/Redd ${ }^{\text {a }}$ | Emigrants/ Redd | Egg-Smolt ${ }^{\text {a }}$ (\%) | Egg-Emigrant (\%) |
| :---: | :---: | :---: | :---: | :---: |
| 2002 | 16 | ND | 0.3 | ND |
| 2003 | 77 | 183 | 1.3 | 3.1 |
| 2004 | 15 | 85 | 0.3 | 1.8 |
| 2005 | 45 | 106 | 1.0 | 2.5 |
| 2006 | 51 | 79 | 1.2 | 1.8 |
| 2007 | 56 | 210 | 1.3 | 4.7 |
| 2008 | 11 | 80 | 0.2 | 1.7 |
| 2009 | 10 | 176 | 0.2 | 3.9 |
| 2010 | 19 | 64 | 0.4 | 1.5 |
| 2011 | 14 | 120 | 0.3 | 2.7 |
| 2012 | 11 | 79 | 0.3 | 1.9 |
| 2013 | 33 | 271 | 0.8 | 6.7 |
| 2014 | 8 | 33 | 0.2 | 0.9 |
| Average | 28 | 124 | 0.6 | 2.8 |
| Median | 16 | 96 | 0.3 | 2.2 |

${ }^{\text {a }}$ These estimates include Nason Creek smolts produced only within the Nason Creek basin.

Seeding level (egg deposition) explained most of the variability in productivity and survival of juvenile spring Chinook in the Nason Creek watershed. That is, for estimates based on smolts produced within the Nason Creek watershed, survival and productivity decreased as seeding levels increased (Figure 6.2). This suggests that density dependence regulates juvenile productivity and survival within the Nason Creek watershed.

## Juvenile Spring Chinook

Figure 6.2. Relationships between seeding levels (egg deposition) and juvenile life-stage survivals and productivities for Nason Creek spring Chinook, brood years 2002-2014. Nason Creek smolts are smolts produced only in the Nason Creek watershed.

## Population Carrying Capacity

Population carrying capacity $(K)$ is defined as the maximum equilibrium population size estimated with population models (e.g., logistic equation, Beverton-Holt model, hockey stick model, and the

Ricker model). ${ }^{16}$ Maximum equilibrium population size is generated from density dependent mechanisms that reduce population growth rates as population size increases (negative density dependence). This is referred to as compensation. Population size fluctuates about the maximum equilibrium size because of variability in vital rates that are unrelated to density (density independent factors) and measurement error. In this section, we estimate smolt carrying capacities using the Ricker stock-recruitment model (see Appendix C in Hillman et al. 2012 for a detailed description of methods). The Ricker model was the only stock-recruitment model that could be fit to the juvenile spring Chinook data.
Based on the Ricker model, the population carrying capacity for spring Chinook smolts in the Nason Creek watershed is 4,412 smolts ( $95 \%$ CI: $0-7,833$ ) (Figure 6.3). Here, smolts are defined as the number of yearling spring Chinook produced entirely within Nason Creek. These estimates reflect current environmental conditions (most recent 13 years) within the Nason Creek watershed. Land use activities such as logging, roads, railways, development, and recreation have altered the historical conditions of the watershed. Thus, the estimated population capacity estimates may not reflect historical capacities for spring Chinook smolts in Nason Creek.

## Nason Creek Spring Chinook Ricker Model

Figure 6.3. Relationship between spawners and number of yearling smolts produced in the Nason Creek watershed. Population carrying capacity ( $K$ ) was estimated using the Ricker model.

[^13]We tracked the precision of the Ricker parameters for Nason Creek spring Chinook smolts over time to see if precision improves with additional years of data, and the parameters and statistics stabilize over time. Examination of variation in the alpha $(A)$ and beta $(B)$ parameters of the Ricker model and their associated standard errors and confidence intervals indicates that the parameters have not stabilized and they lack precision (Table 6.16; Figure 6.4). This was also apparent in the estimates of population carrying capacity (Figure 6.5).

Table 6.16. Estimated parameters and statistics associated with fitting the Ricker model to spawning escapement and smolt data. Smolts represent numbers of smolts produced entirely within the Nason Creek watershed. $A=$ alpha parameter; $B=$ beta parameter; $\mathrm{SE}=$ standard error (estimated from 5,000 bootstrap samples); and $r^{2}=$ coefficient of determination. Spawners represent the stock size needed to achieve population capacity.

| Years ofdata | Parameter |  |  |  | Population capacity | Intrinsic productivity | Spawners | $r^{2}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## Nason Creek Spring Chinook <br> Ricker Model

Figure 6.4. Time series of alpha and beta parameters and $95 \%$ confidence intervals for the Ricker model that was fit to Nason Creek spring Chinook smolt and spawning escapement data. Confidence intervals were estimated from 5,000 bootstrap samples.

Figure 6.5. Time series of population carrying capacity estimates derived from fitting the Ricker model to Nason Creek spring Chinook smolt and spawning escapement data.

### 6.5 Spawning Surveys

Surveys for spring Chinook redds were conducted during late July through September 2016 in the Chiwawa River (including Rock, Chikamin, and Phelps creeks), Nason Creek, Icicle Creek, Peshastin Creek (including Ingalls Creek), Upper Wenatchee River (including Chiwaukum Creek), Little Wenatchee River, and White River (including the Napeequa River and Panther Creek). See Section 5.5 for complete coverage of spring Chinook redd surveys in the Wenatchee River basin. In the following section, we describe the number and distribution of redds within the Nason Creek basin.

## Redd Counts and Distribution

A total of 85 spring Chinook redds were counted in Nason Creek in 2016 (Table 6.17; see Table 5.20 for the complete time series of redd counts). This is lower than the average of 144 redds counted during the period 1989-2015 in Nason Creek. Redds were not distributed evenly among the four reaches in Nason Creek. Most redds (68\%) were located in Reach 2 and Reach 3 (Table 6.17).

Table 6.17. Numbers (both counted and estimated) and proportions of spring Chinook redds counted within different reaches within Nason Creek during August through September 2016. See Table 2.8 for description of survey reaches.

| Stream/watershed | Reach | Number of observed <br> redds | Estimated number of <br> redds* | Proportion of redds <br> estimated within <br> stream/watershed |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Nason | Nason 1 (N1) | 14 | 14 | 0.14 |  |  |  |  |  |
|  | Nason 2 (N2) | 20 | 23 | 0.23 |  |  |  |  |  |
|  | Nason 3 (N3) | 37 | 45 | 0.45 |  |  |  |  |  |
|  | Nason 4 (N4) | 14 | 18 | 0.18 |  |  |  |  |  |
| Total |  |  |  |  |  |  | $\mathbf{8 5}$ | $\mathbf{1 0 0}$ | $\mathbf{1 . 0 0}$ |

* Estimated redds represent the "true" number of redds based on Guassian area-under-the-curve method (see Appendix J).

## Spawn Timing

Spring Chinook began spawning during the last week of July in Nason Creek and peaked the first week of September (Figure 6.6). Spawning in Nason Creek ended the fourth week of September.

## Spring Chinook Redds

Figure 6.6. Proportion of spring Chinook redds counted during different weeks within Nason Creek, August through September 2016.

## Spawning Escapement

Spawning escapement for spring Chinook was calculated as the number of redds times the male-to-female ratio (i.e., fish per redd expansion factor) estimated from broodstock and fish sampled
at adult trapping sites. ${ }^{17}$ The estimated fish per redd ratio for spring Chinook upstream from Tumwater in 2016 was 1.83 (based on sex ratios estimated at Tumwater Dam). Multiplying this ratio by the number of redds counted in Nason Creek resulted in a total spawning escapement of 156 spring Chinook. The estimated total spawning escapement of spring Chinook in 2016 was less than the overall average of 313 spring Chinook in Nason Creek (see Table 5.23).

### 6.6 Carcass Surveys

Surveys for spring Chinook carcasses were conducted during August through September 2016 in the Chiwawa River (including Rock, Chikamin, and Phelps creeks), Nason Creek, Icicle Creek, Peshastin Creek (including Ingalls Creek), Upper Wenatchee River (including Chiwaukum Creek), Little Wenatchee River, and the White River (including the Napeequa River and Panther Creek). In 2016, 95 spring Chinook carcasses were sampled in Nason Creek. Most of these were sampled in Reach 3. The number of carcasses sampled in 2016 was less than the overall average of 148 carcasses sampled during the period 1996-2015. See Section 5.6 for a complete coverage of spring Chinook carcass surveys in the Wenatchee River basin.

In the Nason Creek watershed, the spatial distribution of hatchery and wild fish was not equal among survey reaches (Table 6.18). In 2016, more wild fish were collected during surveys than hatchery fish. On average, over the survey years, more wild fish were collected than hatchery fish in each of the reaches except Reach 1 where more hatchery fish have been collected (Figure 6.7). It should be noted that the hatchery fish spawning in Nason Creek are primarily strays from the Chiwawa spring Chinook Program. Nason Creek hatchery fish began returning to Nason Creek in 2016 as age- 3 fish.

Table 6.18. Numbers of wild and hatchery spring Chinook carcasses sampled within different reaches in the Nason Creek watershed, 1999-2016. Numbers represent recovered carcasses that had definitive origins. See Table 2.8 for description of survey reaches.

| Survey year | Origin | Survey Reach |  |  |  | Total |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## Spring Chinook Carcass Distribution

Figure 6.7. Distribution of wild and hatchery produced carcasses in different reaches in the Nason Creek watershed, 1999-2016. Reach codes are described in Table 2.8.

### 6.7 Life History Monitoring

Life history characteristics of spring Chinook were assessed by examining carcasses on spawning grounds and fish collected at broodstock collection sites, and by reviewing tagging data and fisheries statistics.

## Migration Timing

See Section 5.7 for a description of migration timing of spring Chinook at Tumwater Dam.

## Age at Maturity

Most of the wild and hatchery spring Chinook sampled during the period 1999-2016 in the Nason Creek watershed were age-4 fish (total age) (Table 6.19; Figure 6.8). Except for 2014 fish, hatchery fish made up a higher percentage of age-3 Chinook than did wild fish. As in other years, a higher proportion of age- 5 wild fish returned than did age- 5 hatchery fish. Thus, wild fish tended to return at an older age than hatchery fish.

Table 6.19. Numbers of wild and hatchery spring Chinook of different ages (total age) sampled on spawning grounds in the Nason Creek watershed, 1999-2016.

| Sample year | Origin | Total age |  |  |  |  |  |

## Spring Chinook Age Structure

Figure 6.8. Proportions of wild and hatchery spring Chinook of different total ages sampled on spawning grounds in the Nason Creek watershed for the combined years 1999-2016.

## Size at Maturity

On average, hatchery and wild spring Chinook of a given age differed little in length (Table 6.20). Differences were usually no more than 5 cm between hatchery and wild fish of the same age.

Table 6.20. Mean lengths ( POH in $\mathrm{cm} ; ~ \pm 1 \mathrm{SD}$ ) and sample sizes (in parentheses) of different ages (total age) of male and female spring Chinook of wild and hatchery-origin sampled in the Nason Creek watershed, 1999-2016.

| Return year | Total age | Mean length (cm) |  |  |  |

## Contribution to Fisheries

Because the Nason Creek program began in 2013, there will be no harvest information on Nason Creek hatchery spring Chinook until 2018, when brood year 2013 fish have returned.

## Straying

Stray rates will be determined by examining CWTs and PIT tags recovered on spawning grounds within and outside the Wenatchee River basin. Targets for strays based on return year (recovery year) within the Wenatchee River basin should be less than $10 \%$ and targets for strays outside the Wenatchee River basin should be less than 5\%. The target for brood year stray rates should be less than $5 \%$. Straying of Nason Creek spring Chinook will be estimated beginning in 2017 when the 2013 brood fish return.

## Genetics

Because the Nason Creek spring Chinook program began in 2013 with the collection of broodstock, there are no studies that examine the effects of the program on the genetics of naturalorigin spring Chinook in the Wenatchee River basin. However, genetic studies were conducted to determine the potential effects of the Chiwawa Supplementation Program on natural-origin spring Chinook in the upper Wenatchee River basin (Blankenship et al. 2007; the entire report is appended as Appendix K). This work included the analysis of Nason Creek spring Chinook. Researchers collected microsatellite DNA allele frequencies from temporally replicated natural and hatcheryorigin spring Chinook to statistically assign individual fish to specific demes (locations) within the Wenatchee population.

Significant differences in allele frequencies were observed within and among major spawning areas in the Upper Wenatchee River basin. However, these differences made up only a very small portion of the overall variation, indicating genetic similarity among the major spawning areas. There was no evidence that the Chiwawa program has changed the genetic structure (allele frequency) of spring Chinook in Nason Creek and the White River, despite the presence of hatchery-origin spawners in both systems.

## Proportionate Natural Influence

Another method for assessing the genetic risk of a supplementation program is to determine the influence of the hatchery and natural environments on the adaptation of the composite population. This is estimated by the proportion of natural-origin fish in the hatchery broodstock ( pNOB ) and the proportion of hatchery-origin fish in the natural spawning escapement ( pHOS ). We calculated Proportionate Natural Influence (PNI) by iterating Ford's (2002) equations 5 and 6 to equilibrium, using a heritability of 0.3 and a selection strength of three standard deviations. ${ }^{18}$ The larger the PNI value, the greater the strength of selection in the natural environment relative to that of the hatchery environment. For the natural environment to dominate selection, PNI should be greater than 0.50 , and important integrated populations should have a PNI of at least 0.67 (HSRG/WDFW/NWIFC 2004).

For brood years 1989-2012, when no brood stock was collected for the Nason Creek Program, the PNI values ranged from 0.28 to 1.00 (Table 6.21). During this period, PNI values varied over time because of Chiwawa spring Chinook straying into Nason Creek. For brood years 2013-2016, a period when brood stock was collected for the Nason Creek Program, PNI values for the Nason Creek Program ranged from 0.46 to 0.77 (Table 6.21).
Table 6.21. Proportionate Natural Influence (PNI) Index of hatchery spring Chinook spawning in Nason Creek, brood years 1989-2016. See notes below the table for description of each metric.

| Brood year | Spawners |  |  |  |  | Broodstock |  |  | PNI |

$\mathbf{H O S}_{\mathbf{N}}=$ hatchery-origin spawners in Nason Creek from the Nason Creek spring Chinook Supplementation Program.
$\mathbf{p H O S}_{\mathbf{N}}=$ proportion of hatchery-origin spawners from Nason Creek spring Chinook Supplementation Program.
$\mathbf{H O S}_{\mathbf{s}}=$ stray hatchery-origin spawners in Nason Creek.
$\mathbf{p H O S}_{\mathbf{s}}=$ proportion of stray hatchery-origin spawners.
$\mathbf{N O B}_{\mathbf{N}}=$ natural-origin broodstock spawned in the Nason Creek spring Chinook Supplementation Program.
$\mathbf{H O B}_{\mathrm{N}}=$ hatchery-origin broodstock spawned in the Nason Creek spring Chinook Supplementation Program.
$\mathbf{p N O B}=$ proportion of hatchery-origin broodstock. Because of the high incidence of strays to Nason Creek from the Chiwawa River spring Chinook program, pNOB values from the Chiwawa program were used to estimate PNI values during the period from 1989 to 2012 (italicized). The weighting for those years was $100 \%$ based on the Chiwawa program broodstock selection, because there have been no hatchery returns from the Nason Creek spring Chinook program (see Table 5.1 for Chiwawa broodstock selection).
$\mathbf{P N I}_{\mathbf{N}}=$ Proportionate Natural Influence for Nason Creek spring Chinook calculated using the gene-flow model for multiple programs.

* Average and median for the period 1989-2012, a period when no brood stock were collected for the Nason Creek Program.
** Average and median for the period 2013-present, a period when brood stock was collected for the Nason Creek Program.

## Post-Release Survival and Travel Time

We used PIT-tagged fish to estimate survival rates and travel time (arithmetic mean days) of hatchery spring Chinook from the Nason Creek release site to McNary Dam, and smolt to adult ratios (SARs) from release to detection at Bonneville Dam (Table 6.22). ${ }^{19}$ Over the two brood years for which PIT-tagged hatchery fish were released, survival rates from Nason Creek to McNary Dam ranged from 0.346 to 0.572 . Average travel time from Nason Creek to McNary Dam ranged from 21 to 38 days. SARs from release to detection at Bonneville Dam will be calculated in 2018 with the return of 2013 brood fish.

[^16]Table 6.22. Total number of Nason hatchery spring Chinook released with PIT tags, their survival and travel times (mean days) to McNary Dam, and smolt-to-adult (SAR) ratios for brood years 2013-2014. Standard errors are shown in parentheses. NA = not available (i.e., not all the adults from the release groups have returned to the Columbia River).

| Brood year | Number of tagged <br> fish released | Survival to McNary <br> Dam | Travel time to <br> McNary Dam (d) | SAR to Bonneville <br> Dam |
| :---: | :---: | :---: | :---: | :---: |
| 2013 | 20,139 | $0.346(0.030)$ | $38.1(5.9)$ | NA |
| 2014 | 5,007 | $0.572(0.038)$ | $20.6(5.3)$ | NA |

## Natural and Hatchery Replacement Rates

Natural replacement rates (NRR) were calculated as the ratio of natural-origin recruits (NOR) to the parent spawning population (spawning escapement). Natural-origin recruits are naturally produced (wild) fish that survive to contribute to harvest (directly or indirectly), to broodstock, and to spawning grounds. We do not account for fish that died in route to the spawning grounds (migration mortality) or died just before spawning (pre-spawn mortality) (see Appendix B in Hillman et al. 2012). We calculated NORs with and without harvest. NORs without harvest include all returning fish that either returned to the basin or were collected as wild broodstock. NORs with harvest include all fish harvested and are based on brood-year harvest rates from the Chiwawa Hatchery program. For brood years 1989-2010, NRR for spring Chinook in Nason Creek averaged 0.84 (range, 0.05-5.48) if harvested fish were not included in the estimate and 0.92 (range, 0.055.86 ) if harvested fish were included in the estimate (Table 6.23). NRRs for more recent brood years will be calculated as soon as all tag recoveries and sampling rates have been loaded into the database.

Hatchery replacement rates (HRR) are the hatchery adult-to-adult returns and will be calculated as the ratio of hatchery-origin recruits (HOR) to the parent broodstock collected. These rates should be greater than the NRRs and greater than or equal to 6.7 (the calculated target value in Hillman et al. 2013). The target value of 6.7 includes harvest and was based on HRRs for Chiwawa spring Chinook salmon. HRRs will be calculated beginning in 2018 with the return of 2013 brood fish.

Table 6.23. Spawning escapements, natural-origin recruits (NOR), and natural replacement rates (NRR; with and without harvest) for spring Chinook in the Nason Creek watershed, brood years 1989-2010.

| Brood year | Spawning Escapement | Harvest not included |  | Harvest included |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | NOR | NRR | NOR | NRR |

## Smolt-to-Adult Survivals

Smolt-to-adult survival ratios (SARs) will be calculated as the number of hatchery adult recaptures divided by the number of tagged hatchery smolts released. SARs will be calculated beginning in 2018 with the return of all 2013 brood fish.

### 6.8 ESA/HCP Compliance

## Broodstock Collection

Collection of brood year 2014 broodstock for Nason Creek spring Chinook used a combination of natural-origin adults previously PIT tagged as juveniles and intercepted at Tumwater Dam, and tangle netting in Nason Creek to target up to 64 natural-origin broodstock. Additionally, 130 Chiwawa hatchery-origin adults were collected at Tumwater Dam to secure Grant PUD's Wenatchee spring Chinook production obligation. Total broodstock achieved for the 2014 brood Nason Creek spring Chinook program was 28 and 130 natural and hatchery-origin adults, respectively. A total of 177 bull trout were handled and/or observed during broodstock collection at Tumwater Dam. One bull trout was handled/observed during tangle netting in Nason Creek in 2014.

## Hatchery Rearing and Release

The 2014 brood Nason Creek spring Chinook reared throughout all life stages without significant mortality (defined as $>10 \%$ population mortality associated with a single event). A total of 32,215 WxW and $196,866 \mathrm{HxH}$ smolts were released ( $25.5 \%$ of 2014 conservation program goal and $102.4 \%$ of the aggregate Nason program goal). Survival from green-egg through release survival was $87.4 \%$, well above the $81.0 \%$ target.

From November 2015 through February 2016, a total of five major freshets occurred in the Nason Creek basin resulting in significant damage and blockage of the Nason Acclimation Facility (NAF) intake structure. To minimize the potential for major fish loss, in March 2016 the HxH component (derived from returning Chiwawa hatchery adults) were transferred to the Chiwawa Acclimation facility for the remainder of their rearing and release. This allowed the limited amount of surface water available at the NAF to be prioritized for the small conservation program. No additional mortality occurred as a result of these actions.

## Hatchery Effluent Monitoring

Per ESA Permits 1196, 1347, 1395, 18118, 18120, and 18121, permit holders shall monitor and report hatchery effluents in compliance with applicable National Pollution Discharge Elimination Systems (NPDES) (EPA 1999) permit limitations. There were no NPDES violations reported at PUD Hatchery facilities during the period 1 January through 31 December 2015. NPDES monitoring and reporting for PUD Hatchery Programs during 2015 are provided in Appendix F.

## Smolt and Emigrant Trapping

Per ESA Section 10 Permit No. 1196, 18118, 18120, and 18121 the permit holders are authorized a direct take of $20 \%$ of the emigrating spring Chinook population during juvenile emigration monitoring and a lethal take not to exceed $2 \%$ of the fish captured (NMFS 2003). Based on the estimated wild spring Chinook population (smolt trap expansion) and hatchery juvenile spring Chinook population estimate (hatchery release data) for the Wenatchee River basin, the reported spring Chinook encounters during 2015 emigration monitoring complied with take provisions in the Section 10 permit. Spring Chinook encounter and mortality rates for each trap site (including PIT tag mortalities) are detailed in Table 6.24. Additionally, juvenile fish captured at the trap locations were handled consistent with provisions in ESA Section 10 Permit 1196, 18118, 18120, and 18121, Section B. Table 6.24 includes incidental and direct take associated with the Nason Creek smolt trap operated by the Yakama Nation under separate permits.
Table 6.24. Estimated take of Upper Columbia River spring Chinook resulting from juvenile emigration monitoring in the Wenatchee River basin, 2016.

${ }^{\mathrm{d}}$ Combined trapping and PIT tagging mortality.

## Spawning Surveys

Spring Chinook spawning ground surveys were conducted in the Wenatchee River basin during 2016, as authorized by ESA Section 10 Permits 18118, 18120, and 18121. Because of the difficulty of quantifying the level of take associated with spawning ground surveys, the Permit does not specify a take level associated with these activities, even though it does authorize implementation of spawning ground surveys. Therefore, no take levels are reported. However, to minimize potential effects to established redds, wading was restricted to the extent practical, and extreme caution was used to avoid established redds when wading was required.

## Spring Chinook Reproductive Success Study

ESA Section 10 Permit 1196 (expired) and new Section 10 Permits 18118, 18120, and 18121 specifically provide authorization to capture, anesthetize, biologically sample, PIT tag, and release adult spring Chinook at Tumwater Dam for reproductive success studies and general program monitoring. During 2010 through 2016, all spring Chinook passing Tumwater Dam were enumerated, anesthetized, biologically sampled, PIT tagged, and released (not including hatcheryorigin and natural-origin Chinook retained for broodstock) as a component of the reproductive success study (BPA Project No. 2003-039-00). Please refer to Ford et al. (2010, 2011, 2012, 2013, 2014, 2015, and 2016) for complete details on the methods and results of the spring Chinook reproductive success study for the period 2010-2016.

## SECTION 7: WHITE RIVER SPRING CHINOOK

The White River spring Chinook salmon captive brood program began in 1997 with goals to conserve, aid in the recovery, and prevent the extinction of naturally spawning spring Chinook in the White River, and to meet the mitigation responsibilities of Grant County PUD. Collection of eggs or juveniles from the White River (brood years 1997-2009) made up the first-generation ( $\mathrm{F}_{1}$ ) component of the White River captive brood program. Initially, rearing occurred at AquaSeed in Rochester, Washington, but transitioned to the Little White Salmon National Fish Hatchery near Cook, Washington, in 2006. The $\mathrm{F}_{1}$ component was reared to maturation and spawned within the hatchery. The resulting progeny $\left(\mathrm{F}_{2}\right)$ were then reared in the hatchery until final acclimation and released in the upper Wenatchee Basin. The first large release of $\mathrm{F}_{2}$ juveniles was in 2008. The last release of juveniles from the captive brood program occurred in 2015.

The production goal for the White River captive brood program following the 2013 hatchery recalculation was to release 74,556 yearling smolts into the upper Wenatchee River basin at 18-24 fish per pound. Fish lengths and weights for the recent broods were manipulated to evaluate different approaches for reducing precocious maturation. All fish were marked with CWTs. In addition, from 2008 through 2015, juvenile spring Chinook were PIT tagged annually.

Since its inception, the captive brood program underwent several adaptive changes designed to improve program success. These changes included: (1) use of a pedigree approach to reduce the use of stray fish in the broodstock, (2) transfer of fish from Aquaseed to the Little White Salmon National Fish Hatchery to improve fish quality, (3) injection of hormones into $F_{1}$ females to improve maturation of eggs, (4) manipulation of diet and ration for the $\mathrm{F}_{2}$ fish to reduce precocious maturation of males, (5) use of temporary tanks and natural enclosures during acclimation to improve homing, and (6) trucking juvenile fish around Lake Wenatchee to improve survival.
The following information focuses on results from monitoring the White River spring Chinook program. More detailed information on the White River program can be found in Lauver et al. (2012). Information on spring Chinook collected throughout the Wenatchee River basin is presented in Section 5.

### 7.1 Captive Brood Collection

The captive brood program was designed to provide a rapid, short-term demographic boost to the White River spring Chinook spawning aggregate, which was at a high risk of local extinction (Lauver et al. 2012). This section describes the collection of broodstock for the White River program.

## Brood Collection and Rearing

A primary objective of the White River program was to collect progeny of naturally spawning spring Chinook in the White River. The progeny (eggs or juveniles) make up the first-generation $\left(\mathrm{F}_{1}\right)$ of the captive brood program. However, strays from the Chiwawa supplementation program made this a challenge. As a result, researchers attempted to identify the origin of spawners on redds in the White River and then focused egg and juvenile collection efforts on those redds that had the highest likelihood of being produced from White River parents. During most years, this limited the number of redds from which eggs or juveniles could be collected. Starting with brood
year 2006, a pedigree approach was adopted to improve the likelihood that eggs or juveniles used in the captive brood program were of White River origin.

During 1997 to 2009, first-generation broodstock for the captive brood program originated from about 10,353 natural-origin eggs and juveniles collected from 122 redds in the White River. Broodstock from brood year 1997 were trapped as parr with nets in the fall of 1998. Broodstock from brood year 2006 were trapped as fry with nets in the spring of 2007. It was assumed that the parr and fry near known redds were produced from those redds, and origin was confirmed with pedigree analyses. All other brood years were collected as eggs in the fall using redd pumping techniques. Broodstock collection levels were calculated based on the following assumptions and the known number of suitable redds each year (Tonseth and Maitland 2011):

1. 150,000 smolt target/0.70 (green egg to release survival) $=214,000$ green eggs
2. 214,000 green eggs $/ 1,500$ eggs per female $=143$ females $/ 0.50($ sex ratio $)=286$ fish
3. 286 fish/0.30 (eyed egg to maturity survival) $=953$ eyed eggs
4. 953 eyed eggs/ $\mathbf{X}$ redds $=\mathbf{Y}$ eyed-eggs per redd

Eyed eggs or juveniles collected in the White River were transported to Aquaseed (brood years 1997-2007) or to the Little White Salmon Hatchery (brood years 2008-2009) and reared to adults. Table 7.1 summarizes the collection of eyed eggs or juveniles for the captive brood program.

Table 7.1. Numbers of eyed eggs or juvenile brood stock collected for the White River captive brood program, brood years 1997-2009 (2009 was the last year for broodstock collection). Also shown are the number of redds that were sampled for eggs or juveniles and the hatchery in which the fish were reared (LWSFH = Little White Salmon Fish Hatchery); NS = no sample.

| Brood year | Number of eyed eggs collected | Number of juvenile Chinook collected | Number of redds sampled | Rearing facility |
| :---: | :---: | :---: | :---: | :---: |
| 1997 | 0 | 527 (parr) | 8 | Aquaseed |
| 1998 | 182 | 0 | 4 | Aquaseed |
| 1999 | NS | NS | NS | -- |
| 2000 | 272 | 0 | NS | Aquaseed |
| 2001 | NS | NS | NS | -- |
| 2002 | 167 | 0 | 3 | Aquaseed |
| 2003 | 250 | 0 | 8 | Aquaseed |
| 2004 | 1,216 | 0 | 10 | Aquaseed |
| 2005 | 2,733 | 0 | 21 | Aquaseed/LWSFH ${ }^{1}$ |
| 2006 | 0 | 1,487 (fry) | 29 | Aquaseed/ LWSFH ${ }^{2}$ |
| 2007 | 1,153 | 0 | 13 | Aquaseed/ LWSFH ${ }^{3}$ |
| 2008 | 933 | 0 | 11 | LWSFH |
| 2009 | 1,433 | 0 | 15 | LWSFH |
| Average | 927 | 1,007 | 12 |  |

${ }^{1}$ Fish were transferred on 30 June and 2 July 2008 and 20 January 2009.
${ }^{2}$ Fish were transferred on 21 October and 13 November 2008.
${ }^{3}$ Fish were transferred on 26 September and 21 October 2008.

### 7.2 Hatchery Spawning and Release

## Captive Brood Spawning

As noted above, eyed eggs or juveniles collected in the White River were transported to Aquaseed (for brood years 1997-2007) or to the Little White Salmon Hatchery (for brood years 2008-2009) and reared to adults (Lauver et al. 2012). After rearing broodstock to maturity in captivity, adult spring Chinook were spawned and their progeny were grown to smolt size, acclimated to White River water, and ultimately released into the White River, Lake Wenatchee, or trucked and released below Lake Wenatchee.

During spawning, eggs and sperm were collected and those gametes were crossed based on a $2 \times 2$ factorial spawning matrix. That is, each female was spawned with two males and each male was spawned with two females. Using pedigree analysis, spawning crosses were arranged to maximize genetic diversity. Because incomplete maturation of ova was an issue in the program, implementation of hormone treatments began in 2011 to facilitate maturation. In addition, following spawning, milt from excess males was collected for cryopreservation. Based on a pilot study, the cryopreserved milt was relatively ineffective at fertilizing eggs, so it was not used widely in the program. There are no plans to use the cryopreserved milt in the future. It is noteworthy that most of the males used in spawning were mini-jacks. Table 7.2 shows the ages of first-generation males and females spawned for the captive brood program.
Table 7.2. Total ages of first-generation $\left(\mathrm{F}_{1}\right)$ male and female spring Chinook spawned for the White River captive brood program, spawning years 2001-2011; NA = not available.

| Spawning year | Sex | Total age |  |  |  | Total |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

* Included some unknown number of second-generation females.

## Release Information

## Numbers released

Several different acclimation and release scenarios were conducted since 1997. Acclimation scenarios have involved naturalized features such as in-channel enclosures, stream-side tanks supplied with pass-through surface water, and net pens in Lake Wenatchee near the mouth of the White River. Release scenarios have included on-site releases from tanks, in-channel enclosures, and net pens in Lake Wenatchee. The low survival of fish released in the lake and White River prompted exploring the release of fish near the mouth of the lake and downstream from the lake. In 2010, acclimated fish were towed in net pens to the mouth of the lake and released there. In 2011, tank and net-pen acclimated fish were loaded into transport trucks and released into the Wenatchee River. In addition, subyearling and yearling Chinook with no acclimation have been released from transport trucks directly into Lake Wenatchee and the White River. A total of 944,591 second-generation ( $\mathrm{F}_{2}$ ) juvenile spring Chinook have been released from the captive brood program. Table 7.3 summarizes the acclimation and release history of $\mathrm{F}_{2}$ spring Chinook released into the upper Wenatchee River basin.

* Subyearling release.

## Numbers tagged

Brood years 2005 and 2007-2014 spring Chinook were tagged with a CWT in their peduncle. None of these fish were adipose fin clipped. ${ }^{20}$ Subyearling fish from the 2006 brood year were tagged with half of a CWT in their snouts. Yearling fish from the 2006 brood year were tagged with CWTs in the peduncle. None of these fish were adipose fin clipped. In addition, beginning in 2008 (brood year 2006), 303,207 juvenile spring Chinook have been PIT tagged before release. Table 7.4 identifies the number of second-generation $\left(\mathrm{F}_{2}\right)$ juvenile spring Chinook tagged with PIT tags.

## Post-Release Survival

We used PIT-tagged fish to estimate survival rates and travel time (arithmetic mean days) of released second-generation ( $\mathrm{F}_{2}$ ) White River spring Chinook smolts to McNary Dam, and smolt to adult ratios (SARs) from release to detection at Bonneville Dam. ${ }^{21}$ Based on the available data, post-release survival has been low for fish released into the White River and Lake Wenatchee (Table 7.6). In contrast, survival of fish released in the Wenatchee River tends to be higher than those released in the White River or in Lake Wenatchee. These results suggest that high mortality in Lake Wenatchee may explain why adult returns of program fish have been consistently poor; however, other factors such as high precocious maturation may also contribute to the estimated low survival (e.g., see Ford et al. 2015).
Average travel time from release to McNary Dam ranged from 21 to 82 days (Table 7.6). Spring Chinook released in the Wenatchee River typically traveled faster to McNary Dam than those released in the White River or in Lake Wenatchee. Because of uncertain release times for several groups, we were unable to estimate travel times for all release groups.

[^18]Table 7.6. Survival and travel times (mean days) of second-generation (F2) White River spring Chinook smolts to McNary Dam and SARs to Bonneville Dam for different release scenarios, brood years 20062013. Values in parentheses represent the standard error of the estimate. NA $=$ not available (i.e., not all the fish from the release groups have returned to the Columbia River).

| Brood year | Release scenario | Number of <br> Chinook <br> released with <br> PIT tags | Survival to <br> McNary Dam | Travel time to <br> McNary Dam <br> $(\mathbf{d})$ | SAR to <br> Bonneville Dam |

### 7.3 Disease Monitoring

## First-Generation Health Maintenance

First-generation ( $\mathrm{F}_{1}$ ) adults were fed an azithromycin-medicated feed in the spring to prevent bacterial kidney disease (BKD), which is a common affliction of spring Chinook salmon. As needed, fish received a dose of $20 \mathrm{mg} / \mathrm{kg}$ of body weight. The fish also received formalin treatments as needed throughout the year to prevent and treat fungus infections. This was especially important during the pre-spawning period when individual fish were maturing in preparation for spawning. Formalin treatments were conducted three times per week and consist of one hour of flow-through at a concentration of 167 parts per million (ppm).

## Second-Generation Health Maintenance

Following fertilization and initial incubation in September, second-generation ( $\mathrm{F}_{2}$ ) eggs were shocked in October. Eggs were treated with a $1,667 \mathrm{ppm}$ formalin solution in a 15 -minute flowthrough treatment three times a week to prevent fungus growth. Formalin treatments ended after hatching, and water flow was increased from three to five gallons per minute. Dead and deformed fry were removed before relocating the fry to nursery tanks in late January or early February. Fry were then relocated to raceways in July, where they remained until transfer to the White River for acclimation the following March. Coded-wire tagging was typically conducted in July, and PIT tagging occurred the following January or February, just before the fish were transferred to acclimation facilities on the White River in March.

### 7.4 Natural Juvenile Productivity

Juvenile productivity estimation began with the monitoring of emigration of spring Chinook in the White River in 2007 (Lauver et al. 2012). A five-foot diameter rotary screw trap is operated annually from about 1 March through November. The purpose of the program is to estimate the number and timing of subyearlings and yearling spring Chinook emigrating from the White River basin.

## Smolt and Emigrant Estimates

In 2016, the White River Trap operated between 1 March and 30 November 2016. During that period, the trap was not intentionally disabled under any circumstance. Daily trap efficiencies were estimated by conducting mark-recapture trials. The daily number of fish captured was expanded by the estimated trap efficiency to estimate daily total emigration. If trap efficiencies could not be assessed because of low numbers of juvenile Chinook trapped, a composite model based on efficiency trials from previous years was used to calculate abundance. Daily captures of fish and results of mark-recapture efficiency tests at the White River trap are reported in Appendix M.

Wild yearling spring Chinook (2014 brood year) were captured primarily from March through April 2016 (Figure 7.1). Based on a composite regression model, the total number of wild yearling Chinook emigrating from the White River was $386( \pm 701)$. Combining the total number of subyearling spring Chinook $(1,950 \pm 400)$ that emigrated during the fall of 2015 with the total number of yearling Chinook (386) that emigrated during 2016 resulted in a total emigrant estimate of 2,336 ( $\pm 847$ ) spring Chinook for the 2014 brood year (Table 7.7).

## Juvenile Spring Chinook

Figure 7.1. Monthly captures of wild subyearling (parr) and yearling spring Chinook at the White River Trap, 2016.

${ }^{\text {a }}$ Egg deposition is calculated as the number of redds times the fecundity of both wild and hatchery spring Chinook salmon (from Table 5.5.
${ }^{\mathrm{b}}$ Subyearling emigrants do not include fry that left the watershed before 1 July.
${ }^{\text {c }}$ Average and median are based on the entire time series of data, not just the period 2006 through 2012.

Wild subyearling spring Chinook (2015 brood year) were captured between 7 March and 30 November 2016, with peak catch during August (Figure 7.1). Based on a composite regression model, the total number of wild subyearling Chinook emigrating from the White River was 2,430 ( $\pm 723$ ).

Yearling spring Chinook sampled in 2016 averaged 106 mm in length, 12.4 g in weight, and had a mean condition of 1.05 (Table 7.8). The estimated length and weight were greater than the overall mean of yearling spring Chinook sampled in previous years (overall means, 100 mm and 11.3 g ). The estimated condition for the 2014 brood was less than the overall mean (overall mean, 1.10). Subyearling spring Chinook parr sampled in 2016 at the White River Trap averaged 89 mm in length, averaged 8.3 g , and had a mean condition of 1.13 (Table 7.8). Estimated length and weight were less than the overall mean of subyearling spring Chinook sampled in previous years (overall means, 90 mm and 8.5 g ), while the estimated condition was greater (overall mean, 1.10).
Table 7.8. Mean fork length ( mm ), weight ( g ), and condition factor of subyearling (parr) and yearling spring Chinook collected in the White River Trap, 2007-2016. Numbers in parentheses indicate 1 standard deviation.

${ }^{\text {a }}$ Sample size represents the number of fish that were measured for both length and weight.

## Freshwater Productivity

Both productivity and survival estimates for different life stages of spring Chinook in the White River basin are provided in Table 7.9. Estimates for brood year 2014 generally fall below the range of productivity and survival estimates for brood years 2005-2013. During that period, freshwater productivities ranged from 15-170 smolts/redd and 85-347 emigrants/redd. Survivals during the same period ranged from $0.4-3.8 \%$ for egg-smolt and 2.0-7.5\% for egg-emigrants.
Table 7.9. Productivity (fish/redd) and survival (\%) estimates for different juvenile life stages of spring Chinook in the White River basin for brood years 2005-2014. These estimates were derived from data in Table 7.7. ND = no data.

| Brood year | Smolts/Redd $^{\mathbf{a}}$ | Emigrants/Redd | Egg-Smolt $^{\mathbf{~}}$ (\%) | Egg-Emigrant (\%) |
| :---: | :---: | :---: | :---: | :---: |
| 2005 | 56 | ND | 1.3 | ND |
| 2006 | 65 | 85 | 1.5 | 2.0 |
| 2007 | 170 | 285 | 3.8 | 6.4 |
| 2008 | 168 | 347 | 3.6 | 7.5 |
| 2009 | 54 | 100 | 1.2 | 2.2 |

| Brood year | Smolts/Redd $^{\mathbf{a}}$ | Emigrants/Redd | Egg-Smolt $^{\mathbf{a}}{ }^{\text {(\%) }}$ | Egg-Emigrant (\%) |
| :---: | :---: | :---: | :---: | :---: |
| 2010 | 125 | 181 | 2.9 | 4.2 |
| 2011 | 83 | 239 | 1.9 | 5.5 |
| 2012 | 46 | 92 | 1.1 | 2.2 |
| 2013 | 56 | 102 | 1.2 | 2.2 |
| 2014 | 15 | 90 | 0.4 | 2.2 |
| Average | $\mathbf{8 4}$ | $\mathbf{1 6 9}$ | $\mathbf{1 . 9}$ | $\mathbf{3 . 8}$ |
| Median | $\mathbf{6 1}$ | $\mathbf{1 0 2}$ | $\mathbf{1 . 4}$ | $\mathbf{2 . 2}$ |

${ }^{\text {a }}$ These estimates include White River smolts produced only within the White River basin.

Seeding level (egg deposition) explained part of the variability in productivity and survival of juvenile spring Chinook in the White River basin. That is, for estimates based on smolts produced within the White River basin, survival and productivity decreased as seeding levels increased (Figure 7.2). This suggests that density dependence in part regulates juvenile productivity and survival within the White River basin.

## Juvenile Spring Chinook

Figure 7.2. Relationships between seeding levels (egg deposition) and juvenile life-stage survivals and productivities for White River spring Chinook, brood years 2005-2014. White River smolts are smolts produced only within the White River basin.

## Population Carrying Capacity

Population carrying capacity $(K)$ is defined as the maximum equilibrium population size estimated with population models (e.g., logistic equation, Beverton-Holt model, hockey stick model, and the

Ricker model). ${ }^{22}$ Maximum equilibrium population size is generated from density dependent mechanisms that reduce population growth rates as population size increases (negative density dependence). This is referred to as compensation. Population size fluctuates about the maximum equilibrium size because of variability in vital rates that are unrelated to density (density independent factors) and measurement error. In this section, we estimate smolt carrying capacities using the Ricker stock-recruitment model (see Appendix C in Hillman et al. 2012 for a detailed description of methods). The Ricker model was the only stock-recruitment model that could be fit to the juvenile spring Chinook data.
Based on the Ricker model, the population carrying capacity for spring Chinook smolts in the White River basin is 4,659 smolts ( $95 \%$ CI: $0-7,075$ ) (Figure 7.3). Here, smolts are defined as the number of yearling spring Chinook produced entirely within the White River basin. These estimates reflect current conditions (most recent decades) within the White River basin. Land use activities such as logging, roads, development, and recreation have altered the historical conditions of the watershed. Thus, the estimated population capacity estimates may not reflect historical capacities for spring Chinook smolts in the White River basin.

## White River Spring Chinook Ricker Model

Figure 7.3. Relationship between spawners and number of smolts produced in the White River basin. Population carrying capacity ( $K$ ) was estimated using the Ricker model.

[^19]We tracked the precision of the Ricker parameters for White River spring Chinook smolts over time to see if precision improves with additional years of data, and the parameters and statistics stabilize over time. Examination of variation in the alpha $(A)$ and beta $(B)$ parameters of the Ricker model and their associated standard errors and confidence intervals indicates that the parameters have not stabilized and lack precision (Table 7.10; Figure 7.4). This was also apparent in the estimates of population carrying capacity (Figure 7.5).

Table 7.10. Estimated parameters and statistics associated with fitting the Ricker model to spawning escapement and smolt data. Smolts represent numbers of smolts produced entirely within the White River basin. $A=$ alpha parameter; $B=$ beta parameter; $\mathrm{SE}=$ standard error (estimated from 5,000 bootstrap samples); and $r^{2}=$ coefficient of determination. Spawners represent the stock size needed to achieve population capacity.

| Years of <br> data | Parameter |  |  |  |  | Population |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | $\boldsymbol{A}$ | Intrinsic <br> capacity | Spawners | $\boldsymbol{r}^{2}$ |  |  |  |  |

### 7.5 Spawning Surveys

Surveys for spring Chinook redds were conducted during August through September 2016 in the Chiwawa River (including Rock, Phelps, and Chikamin creeks), Nason Creek, Icicle Creek, Peshastin Creek (including Ingalls Creek), Upper Wenatchee River (including Chiwaukum Creek), Little Wenatchee River, and White River (including the Napeequa River and Panther Creek). See Section 5.5 for a complete coverage of spring Chinook redd surveys in the Wenatchee River basin. In the following section, we describe the number and distribution of redds within the White River basin.

## Redd Counts and Distribution

A total of 44 spring Chinook redds were counted in the White River basin in 2016 (Table 7.11; see Table 5.20 for the complete time series of redd counts). This is higher than the average of 35 redds counted during the period 1989-2015 in the White River. Redds were not distributed evenly among the six survey areas in the White River basin. Most redds (81\%) were located in Reach 3 (Napeequa River to Grasshopper Meadows) in the White River (Table 7.11).

Table 7.11. Numbers (both observed and estimated) and proportions of spring Chinook redds counted within different survey areas within the White River basin during August through September 2016. See Table 2.8 for description of survey reaches.

| Stream/watershed | Reach | Number of observed redds | Estimated number of redds* | Proportion of estimated redds within stream/watershed |
| :---: | :---: | :---: | :---: | :---: |
| White River | White 1 (H1) | 0 | -- | -- |
|  | White 2 (H2) | 4 | 6 | 0.11 |
|  | White 3 (H3) | 37 | 43 | 0.81 |
|  | White 4 (H4) | 2 | 3 | 0.06 |
|  | Napeequa 1 (Q1) | 1 | 1 | 0.02 |
|  | Panther 1 (T1) | 0 | 0 | 0.00 |
| Total |  | 44 | 53 | 1.00 |

* Estimated redds represent the "true" number of redds based on Guassian area-under-the-curve method (see Appendix J).

## Spawn Timing

Spring Chinook began spawning during the third week of August in the White River and peaked the second week of September (Figure 7.6). Spawning in the White River ended the third week of September.

Spring Chinook Redds

Figure 7.6. Proportion of spring Chinook redds counted during different weeks within the White River basin, August through September 2016.

## Spawning Escapement

Spawning escapement for spring Chinook was calculated as the number of redds times the male-to-female ratio (i.e., fish per redd expansion factor) estimated from broodstock and fish sampled
at adult trapping sites. ${ }^{23}$ The estimated fish per redd ratio for spring Chinook upstream from Tumwater in 2016 was 1.83 (based on sex ratios estimated at Tumwater Dam). Multiplying this ratio by the number of redds counted in the White River basin resulted in a total spawning escapement of 81 spring Chinook. The estimated total spawning escapement of spring Chinook in 2016 was greater than the overall average of 76 spring Chinook in the White River basin (see Table 5.23).

### 7.6 Carcass Surveys

Surveys for spring Chinook carcasses were conducted during August through September 2016 in the Chiwawa River (including Rock, Phelps, and Chikamin creeks), Nason Creek, Icicle Creek, Peshastin Creek (including Ingalls Creek), Upper Wenatchee River (including Chiwaukum Creek), Little Wenatchee River, and the White River (including the Napeequa River and Panther Creek). In 2016, 13 spring Chinook carcasses were sampled in the White River basin. Most of these were sampled in Reach 3. The total number of carcasses sampled in 2016 was less than the overall average of 20 carcasses sampled during the period 1996-2015. See Section 5.6 for a complete coverage of spring Chinook carcass surveys in the Wenatchee River basin.
In the White River basin, the spatial distribution of hatchery strays (primarily from the Chiwawa Spring Chinook program) and wild spring Chinook was not equal (Table 7.12). Only one carcass was recovered in Reach 2, which was of hatchery origin, while Reach 3 had primarily wild fish ( $91 \%$ ). In 2016, most carcasses ( $85 \%$ ) were observed in the reach between the Napeequa River and Grasshopper Meadows (Reach 3) (Table 7.12). Over the years, spring Chinook have spawned more often in this reach than in other reaches (Figure 7.7).
Table 7.12. Numbers of wild, hatchery strays, and captive brood spring Chinook carcasses sampled within different reaches in the White River basin, 2000-2016. Numbers represent recovered carcasses that had definitive origins. See Table 2.8 for description of survey reaches.

| Survey year | Origin | Survey Reach |  |  |  |  | Total |

Spring Chinook Carcass Distribution

Figure 7.7. Distribution of wild, hatchery strays, and captive brood produced carcasses in different reaches in the White River basin, 2000-2016. Reach codes are described in Table 2.8.

### 7.7 Life History Monitoring

Life history characteristics of spring Chinook were assessed by examining carcasses on spawning grounds and fish collected at broodstock collection sites, and by reviewing tagging data and fisheries statistics.

## Migration Timing

See Section 5.7 for a description of migration timing of spring Chinook at Tumwater Dam.

## Age at Maturity

Most of the wild and hatchery stray spring Chinook sampled during the period 2001-2016 in the White River basin were age-4 fish (total age) (Table 7.13; Figure 7.8). A higher proportion of age5 wild fish returned than did age- 5 hatchery strays. Thus, wild fish tended to return at an older age than hatchery strays. Currently, few captive brood carcasses have been identified on the spawning grounds; most were age-4 and one was age-5. There has been a conspicuous absence of age- 3 fish recovered as carcasses. In all years except 2007, no age-3 carcasses have been recovered.
Table 7.13. Numbers of wild, hatchery strays, and captive brood spring Chinook of different ages (total age) sampled on spawning grounds in the White River basin, 2001-2016.

| Sample year | Origin | Total age |  |  |  |  |  |

## Spring Chinook Age Structure

Figure 7.8. Proportions of wild, hatchery strays, and captive brood spring Chinook of different total ages sampled on spawning grounds in the White River basin for the combined years 2000-2016.
For comparison, Table 7.14 and Figure 7.9 show the age structure of spring Chinook carcasses sampled in the Little Wenatchee River. Similar to the White River, most of the wild and hatchery stray spring Chinook sampled during the period 2001-2016 in the Little Wenatchee River basin were age- 4 fish (total age). A higher proportion of age- 5 wild fish returned than did age- 5 hatchery strays. Thus, wild fish tended to return at an older age than hatchery strays. As in the White River, few age-3 fish have been recovered in the Little Wenatchee River.

Table 7.14. Numbers of wild and hatchery stray spring Chinook of different ages (total age) sampled on spawning grounds in the Little Wenatchee River basin, 2001-2016.

## Spring Chinook Age Structure

Figure 7.9. Proportions of wild and hatchery stray spring Chinook of different total ages sampled on spawning grounds in the Little Wenatchee River basin for the combined years 2000-2016.

## Size at Maturity

On average, hatchery strays and wild spring Chinook of a given age differed little in length (Table 7.15). Differences were small ( $1-2 \mathrm{~cm}$ ) and no more than 9 cm between hatchery strays and wild fish of the same age. Few captive brood carcasses have been identified on the spawning grounds; most were females. Those fish were about the same size as wild and hatchery strays of the same age.
Table 7.15. Mean lengths ( POH in $\mathrm{cm} ; ~ \pm 1 \mathrm{SD}$ ) and sample sizes (in parentheses) of different ages (total age) of male and female spring Chinook of wild, hatchery strays, and captive brood origin sampled in the White River basin, 2001-2016.

| Return year | Total age | Mean length (cm) |  |  |  |  |  |

## Contribution to Fisheries

No White River spring Chinook from the captive brood program tagged with CWTs or PIT tags have been recaptured (or reported) in ocean or Columbia River (tribal, commercial, or recreational) fisheries.

## Straying

Stray rates of White River spring Chinook from the captive brood program were determined by examining the locations where PIT-tagged Chinook demonstrating anadromy (based on detections at Bonneville Dam) were last detected. PIT tagging of White River spring Chinook began with release year 2008, which allows estimation of stray rates by brood return. Targets for strays based on return year (recovery year) within the Wenatchee River basin should be less than $10 \%$ and targets for strays outside the Wenatchee River basin should be less than 5\%. The target for brood year stray rates should be less than $5 \%$.
Based on PIT-tag analyses, on average, about $61 \%$ of the White River spring Chinook returns were last detected in streams outside the White River (Table 7.16). The numbers in Table 7.16 should be considered rough estimates because they are not based on confirmed spawning (only last detections) and they represent small sample sizes. In addition, last detections in adult fishways (i.e., Bonneville, Rock Island, and Tumwater dams) were not included, nor were detections in areas outside the distribution of known spring Chinook spawning (i.e., Lower and Middle Wenatchee River). All fish reported in Table 7.16 are at least age- 3 fish (total age) and some of them may not have migrated all the way to the ocean but rather resided completely in freshwater downstream from Bonneville Dam.

Table 7.16. Number and percent of White River spring Chinook from the captive brood program that homed to target spawning areas on the White River and the target hatchery program (Little White Salmon Fish Hatchery), and number and percent that strayed to non-target spawning areas and hatchery programs for brood years 2006-2011. Only PIT-tagged fish demonstrating anadromy were included in the analysis. Estimates were based on last detections of PIT-tagged spring Chinook. Percent strays should be less than 5\%.

| Median | 1 | 7.2 | 0 | 0.0 | 11 | 84.3 | 0 | 0.0 |

* Homing to the target hatchery includes White River hatchery spring Chinook that are captured and included as broodstock in the White River Hatchery program.
The percentage of the PIT-tagged White River spring Chinook from the captive brood program that were last detected in different watersheds within and outside the Wenatchee River basin are shown in Table 7.17. On average, a small percentage of the PIT-tagged White River spring Chinook homed to the White River. Relatively high percentages of them were last detected in the Little Wenatchee River, Upper Wenatchee River, Nason Creek, and the Chiwawa River.
Few returning adults have strayed into spawning areas outside the Wenatchee River basin. One was last detected in the Entiat River. No other returning adults were detected outside the Wenatchee River basin. On the other hand, several juveniles were last detected in rivers outside the Wenatchee River basin. Juveniles were last detected in the Deschutes, Walla Walla, Hood, and North Fork Teanaway rivers. Juveniles were also last detected at the Little White Salmon Fish Hatchery. There is no evidence that these fish entered the ocean and returned as adults.
Table 7.17. Number and percent (in parentheses) of PIT-tagged White River spring Chinook from the captive brood program that were last detected in different tributaries within the Wenatchee River basin, return years 2010-2016. Only PIT-tagged fish demonstrating anadromy were included in the analysis.

## Genetics

At this time, there are no studies that examine the effects of the White River captive brood program on the genetics of natural-origin spring Chinook in the Wenatchee River basin. However, genetic studies were conducted to determine the potential effects of the Chiwawa Supplementation Program on natural-origin spring Chinook in the upper Wenatchee River basin (Blankenship et al. 2007; the entire report is appended as Appendix K). This work included the analysis of White River spring Chinook. Researchers collected microsatellite DNA allele frequencies from temporally replicated natural and hatchery-origin spring Chinook to statistically assign individual fish to specific demes (locations) within the Wenatchee population.

Significant differences in allele frequencies were observed within and among major spawning areas in the Upper Wenatchee River basin. However, these differences made up only a very small portion of the overall variation, indicating genetic similarity among the major spawning areas. There was no evidence that the Chiwawa program has changed the genetic structure (allele frequency) of spring Chinook in the White River, despite the presence of hatchery-origin spawners in both systems.

## Proportionate Natural Influence

Another method for assessing the genetic risk of a supplementation program is to determine the influence of the hatchery and natural environments on the adaptation of the composite population. This is estimated by the proportion of natural-origin fish in the hatchery broodstock ( pNOB ) and the proportion of hatchery-origin fish in the natural spawning escapement ( $\mathrm{pHOS} \mathrm{)}$. Proportionate Natural Influence (PNI) by iterating Ford's (2002) equations 5 and 6 to equilibrium, using a heritability of 0.3 and a selection strength of three standard deviations. ${ }^{24}$ The larger the PNI value, the greater the strength of selection in the natural environment relative to that of the hatchery environment. In order for the natural environment to dominate selection, PNI should be greater than 0.50 , and important integrated populations should have a PNI of at least 0.67 (HSRG/WDFW/NWIFC 2004).

For brood years 1989-2000, PNI values ranged from 0.95 to 1.00 (Table 7.18). For brood years 2001-2013, PNI for the White River Program averaged 0.60 (range, 0.33-1.00) (Table 7.18).

[^21]Table 7.18. Proportionate Natural Influence (PNI) values for hatchery spring Chinook spawning in the White River, brood years 1989-2013. See notes below the table for description of each metric.

| Brood year | Spawners |  |  |  |  | Broodstock |  |  | PNI |

$\mathbf{H O S}_{\mathbf{W}}=$ hatchery-origin spawners in White River from the White River spring Chinook Supplementation Program.
$\mathbf{p H O S}_{\mathbf{w}}=$ proportion of hatchery-origin spawners from White River spring Chinook Supplementation Program.
$\mathbf{H O S}_{\mathbf{s}}=$ stray hatchery-origin spawners in the White River.
$\mathbf{p H O S}_{\mathbf{s}}=$ proportion of stray hatchery-origin spawners.
$\mathbf{N O B}_{\mathbf{w}}=$ natural origin broodstock spawned for the White River spring Chinook Supplementation Program.
$\mathbf{H O B}_{\mathbf{W}}=$ hatchery-origin broodstock spawned in the White River spring Chinook Supplementation Program.
$\mathbf{p N O B}=$ proportion of hatchery-origin broodstock. Because of the high incidence of strays to the White River from the Chiwawa River spring Chinook program, pNOB values from the Chiwawa program were used to estimate PNI values during the period from 1989 to 2000 (italicized). The weighting for those years was $100 \%$ based on the Chiwawa program broodstock selection, because there have been no hatchery returns from the White River spring Chinook program during this period (see Table 5.1 for Chiwawa broodstock selection).
PNI = Proportionate Natural Influence for White River spring Chinook calculated using the gene-flow model for multiple programs.

* Average and median for the period 1989-2000.
** Average and median for the period 2001-2013.

## Natural and Hatchery Replacement Rates

In general, natural replacement rates (NRR) are calculated as the ratio of natural-origin recruits (NOR) to the parent spawning population (spawning escapement). Natural-origin recruits are naturally produced (wild) fish that survive to contribute to harvest (directly or indirectly), to broodstock, and to spawning grounds. We do not account for fish that died in route to the spawning grounds (migration mortality) or died just before spawning (pre-spawn mortality) (see Appendix B in Hillman et al. 2012). We calculated NORs with and without harvest. NORs include all returning fish that either returned to the basin or were collected as wild broodstock. For brood years 1989-2010, NRR for spring Chinook in the White River basin averaged 1.03 (range, 0.004.91 ) if harvested fish were not included in the estimate and 1.25 (range, 0.00-5.91) if harvested fish were included in the estimate (Table 7.19). NRRs for more recent brood years will be calculated as soon as all tag recoveries and sampling rates have been loaded into the database.

Hatchery replacement rates (HRR) are the hatchery adult-to-adult returns and are calculated as the ratio of hatchery-origin recruits (HOR) to the parent broodstock collected. For brood years 20062010, hatchery replacement rates averaged 0.17 (range, $0.00-0.48$ ) if harvest is not included and 0.62 (range, 0.00-1.99) if harvest is included (Table 7.19a). Only for brood year 2009 was HRR greater than the NRR. The HRR values are much higher when they are calculated using the number of adult equivalents taken from the natural environment to initiate the captive brood program (Table 7.19b).

Table 7.19a. Numbers of brood stock spawned, spawning escapements, hatchery-origin recruits (HOR), natural-origin recruits (NOR), hatchery replacement rates (HRR), and natural replacement rates (NRR) with and without harvest for spring Chinook in the White River basin, brood years 1989-2010.

${ }^{1}$ HOR and HRR values represented here are detections of PIT-tag hatchery fish detected at Tumwater Dam. These values have been expanded based on the untagged proportion of fish released from the White River spring Chinook Program and PIT-tag detection efficiency at Tumwater Dam.
${ }^{2}$ NOR and NRR values represented here are based on carcasses recovery in the White River adjusted by $\mathrm{H}: \mathrm{W}$ ratios and age composition and expanded to the escapement in the White River.
${ }^{3}$ Harvest on hatchery-origin White River spring Chinook was estimated based on harvest rates observed for Chiwawa spring Chinook.
${ }^{4}$ Expanded NORs for harvest were based on harvest rates from Chiwawa River spring Chinook.
Table 7.19b. Hatchery-origin recruits (HOR) and hatchery replacement rates (HRR) based on adult equivalents for spring Chinook in the White River basin, brood years 2006-2009. HORs were estimated at Tumwater Dam.

| Brood year | Adult equivalents | Harvest not included |  | Harvest included |  |

| Median | $\mathbf{1 . 0 4}$ | $\mathbf{1 8}$ | $\mathbf{4 4}$ | $\mathbf{8 3}$ | $\mathbf{1 2 4}$ |

For comparison, we calculated NRR for spring Chinook within the Little Wenatchee River basin. Fish from both the White River and Little Wenatchee River must migrate through Lake Wenatchee. Therefore, a comparison between the two subpopulations is appropriate.
NRRs for spring Chinook in the Little Wenatchee River basin were generally less than those for spring Chinook in the White River basin. For brood years 1989-2010, NRR for spring Chinook in the Little Wenatchee River basin averaged 0.83 (range, $0.00-4.50$ ) if harvested fish were not included in the estimate and 1.01 (range, 0.00-5.28) if harvested fish were included in the estimate (Table 7.20). NRRs for more recent brood years will be calculated as soon as all tag recoveries and sampling rates have been loaded into the database.
Table 7.20. Spawning escapements, natural-origin recruits (NOR), and natural replacement rates (NRR) with and without harvest for spring Chinook in the Little Wenatchee River basin, brood years 1989-2010.

## Smolt-to-Adult Survivals

Smolt-to-adult survival ratios (SARs) were calculated as the number of hatchery adults detected at Tumwater Dam divided by the number of tagged hatchery smolts released. SARs were based on PIT-tag detections. For the available brood years, SARs have ranged from 0.00000 to 0.00196 (Table 7.21).
Table 7.21. Smolt-to-adult ratios (SARs) for White River spring Chinook from the captive brood program, brood years 2006-2011. Detections at Tumwater Dam are adjusted for PIT-tag detection efficiency.

| Brood year | Number of smolts <br> released | Number of PIT- <br> tagged smolts <br> released | PIT-tags | Adjusted Tumwater <br> Detections |
| :---: | :---: | :---: | :---: | :---: |
| 2006 |  |  | 1 | 0.00003 |
| 2007 | 131,843 | 39,820 | 0 | 0.00000 |

| :---: | :---: | :---: | :---: | :---: |
|  |  |  | Adjusted Tumwater Detections | SAR |
| 2011 | 147,000 | 54,187 | 106 | 0.00196 |
| Average | 100,146 | 36,094 | 30 | 0.00068 |
| Median | 122,220 | 39,235 | 15 | 0.00054 |

### 7.8 ESA/HCP Compliance

## Brood Collection

The last collection of eggs or fry for this program occurred in 2010 (brood year 2009). From 2011 to 2013, the White River Captive Brood Program operated without ESA permit coverage. The hatchery program ended with the last release of juveniles in 2015 (brood year 2013).

## Hatchery Rearing, Spawning, and Release

From 2011 to 2013, the White River Captive Brood Program has operated without ESA permit coverage. The hatchery program ended with the last release of juveniles in 2015 (brood year 2013). No release of juveniles occurred under Section 10(a)(1)(A) Permit 18120 in 2016.

## Hatchery Effluent Monitoring

No juveniles were reared or released as part of the White River captive brood program in 2016 due to sun-setting of the program with the 2013 brood. Therefore, no effluent monitoring was required or conducted in 2016.

## Smolt and Emigrant Trapping

Per ESA Section 10 Permit No. 1196 (expired), 18118, 18120, and 18121, the permit holders are authorized a direct take of $20 \%$ of the emigrating spring Chinook population during juvenile emigration monitoring and a lethal take not to exceed $2 \%$ of the fish captured (NMFS 2003). Based on the estimated wild spring Chinook population (smolt trap expansion) and hatchery juvenile spring Chinook population estimate (hatchery release data) for the Wenatchee River basin, the reported spring Chinook encounters during 2016 emigration monitoring complied with take provisions in the Section 10 permit. Spring Chinook encounter and mortality rates for each trap site (including PIT tag mortalities) are detailed in Table 7.22. Additionally, juvenile fish captured at the trap locations were handled consistent with provisions in ESA Section 10 Permit 1196 (expired), 18118, 18120, and 18121, Section B. Table 7.22 includes incidental or direct take associated with the White River smolt trap operated by the Yakama Nation under separate permits.

Table 7.22. Estimated take of Upper Columbia River spring Chinook resulting from juvenile emigration monitoring in the Wenatchee River basin, 2016.

${ }^{\mathrm{b}} 2016$ BY smolt release data for the Wenatchee River basin.
${ }^{c}$ Based on size, date of capture and location of capture, subyearling Chinook encountered at the Lower Wenatchee Trap are categorized as summer Chinook salmon.
${ }^{\mathrm{d}}$ Combined trapping and PIT tagging mortality.

## Spawning Surveys

Spring Chinook spawning ground surveys were conducted in the Wenatchee River basin during 2016, as authorized by ESA Section 10 Permits 18118, 18120, and 18121. Because of the difficulty of quantifying the level of take associated with spawning ground surveys, the Permit does not specify a take level associated with these activities, even though it does authorize implementation of spawning ground surveys. Therefore, no take levels are reported. However, to minimize potential effects to established redds, wading was restricted to the extent practical, and extreme caution was used to avoid established redds when wading was required.

## Spring Chinook Reproductive Success Study

ESA Section 10 Permit 1196 (expired) and new Section 10 Permits 18118, 18120, and 18121 specifically provide authorization to capture, anesthetize, biologically sample, PIT tag, and release adult spring Chinook at Tumwater Dam for reproductive success studies and general program monitoring. During 2010 through 2016, all spring Chinook passing Tumwater Dam were enumerated, anesthetized, biologically sampled, PIT tagged, and released (not including hatcheryorigin and natural-origin Chinook retained for broodstock) as a component of the reproductive success study (BPA Project No. 2003-039-00). Please refer to Ford et al. (2010, 2011, 2012, 2013, 2014, 2015, and 2016) for complete details on the methods and results of the spring Chinook reproductive success study for the period 2010-2016.

## SECTION 8: WENATCHEE SUMMER CHINOOK

The goal of summer Chinook salmon supplementation in the Wenatchee Basin is to use artificial production to replace adult production lost because of mortality at Priest Rapids, Wanapum, and Rock Island dams, while not reducing the natural production or long-term fitness of summer Chinook in the basin. The Rock Island Fish Hatchery Complex began operation in 1989 under funding from Chelan PUD and subsequently Grant PUD began cost-sharing the program in 2012. The Complex operated originally through the Rock Island Settlement Agreement, but since 2004 has operated under the Anadromous Fish Agreement and Habitat Conservation Plans as well as the Priest Rapids Project Salmon and Steelhead Settlement Agreement.

Adult summer Chinook are collected for broodstock from the run-at-large at the right and leftbank traps at Dryden Dam, and at Tumwater Dam if the weekly quotas cannot be achieved at Dryden Dam. Before 2012, the goal was to collect up to 492 natural-origin adult summer Chinook for the Wenatchee program for an annual release of 864,000 smolts. In 2011, the Hatchery Committees reevaluated the amount of hatchery compensation needed to achieve NNI. Based on that evaluation, the goal of the program was revised. The current goal (beginning in 2012) is to collect up to 256 adult natural-origin summer Chinook for an annual release of 500,001 smolts. Broodstock collection occurs from about 1 July through 15 September with trapping occurring up to 24 hours per day, seven days a week. If natural-origin broodstock collection falls short of expectation, hatchery-origin adults can be collected to make up the difference.
Adult summer Chinook are spawned and reared at Eastbank Fish Hatchery. Juvenile summer Chinook are transferred from the hatchery to Dryden Acclimation Pond in March. They are released from the pond in late April to early May.
Before 2012, the production goal for the Wenatchee summer Chinook supplementation program was to release 864,000 yearling smolts into the Wenatchee River at ten fish per pound. Beginning with the 2012 brood, the revised production goal is to release 500,001 yearling smolts into the Wenatchee River at 10 and 15 fish per pound. Targets for fork length and weight are 163 mm (CV $=9.0)$ and 45.4 g , respectively. Over $95 \%$ of these fish are marked with CWTs. In addition, since 2009, about 10,000 juvenile summer Chinook have been PIT tagged annually.

### 8.1 Broodstock Sampling

This section focuses on results from sampling 2014-2016 Wenatchee summer Chinook broodstock, which were collected at Dryden and Tumwater dams.

## Origin of Broodstock

Consistent with the broodstock collection protocol, the 2014-2016 broodstock consisted primarily of natural-origin (adipose fin present and no CWT) summer Chinook (Table 8.1). Less than $1 \%$ of the 2014-2016 broodstock was comprised of hatchery-origin fish (hatchery-origin was determined by examination of scales and/or CWTs).

Table 8.1. Numbers of wild and hatchery summer Chinook collected for broodstock, numbers that died before spawning, and numbers of Chinook spawned, 1989-2016. Unknown origin fish (i.e., undetermined by scale analysis, no CWT or fin clips, and no additional hatchery marks) were considered naturally produced. Mortality includes fish that died of natural causes typically near the end of spawning and were not needed for the program and surplus fish killed at spawning.

| Brood year | Wild summer Chinook |  |  |  |  | Hatchery summer Chinook |  |  |  |  | Total number spawned |

${ }^{\text {a }}$ Pre-spawn loss represents the number of fish that died during the holding period before spawning. Mortality is the number of fish that were surplused following spawning.
${ }^{\text {a }}$ This average represents the program before recalculation in 2011.
${ }^{\mathrm{b}}$ This average represents the current program, which began in 2012.

## Age/Length Data

Ages of summer Chinook broodstock were determined from analysis of scales and/or CWTs. Broodstock collected from the 2014 return consisted primarily of age- 4 and age- 5 natural-origin Chinook ( $94.7 \%$ ). Age-3 and age-6 natural-origin fish made up $4.5 \%$ and $0 \%$ of the broodstock,
respectively (Table 8.2). The two hatchery Chinook included in the broodstock were age-4 and age-5 fish.
Broodstock collected from the 2015 return consisted primarily of age-4 and age-5 natural-origin Chinook ( $92.1 \%$ ). Age-3 and age-6 natural-origin fish made up $7.8 \%$ and $0 \%$ of the broodstock, respectively (Table 8.2). No hatchery Chinook were included in broodstock.

Broodstock collected from the 2016 return consisted primarily of age-4 and age-5 natural-origin Chinook ( $98.4 \%$ ). Age- 3 and age- 6 natural-origin fish made up $1.3 \%$ and $0.4 \%$ of the broodstock, respectively (Table 8.2). No hatchery Chinook were included in broodstock.
Table 8.2. Percent of hatchery and wild Wenatchee summer Chinook of different ages (total age) collected from broodstock in the Wenatchee River basin, 1991-2016.

## Sex Ratios

Male summer Chinook in the 2014 and 2015 broodstock made up nearly $50 \%$ of the adults collected, resulting in overall male to female ratios of 0.99:1.00 and 0.99:1.00, respectively (Table 8.4). In 2016, males made up just under $50 \%$ of the adults collected, resulting in an overall male to female ratio of 0.99:1.00 (Table 8.4). The ratios in 2014-2016 were nearly equal to the 1:1 ratio goal in the broodstock protocol.

Table 8.4. Numbers of male and female wild and hatchery summer Chinook collected for broodstock in the Wenatchee River basin, 1989-2016. Ratios of males to females are also provided.

| Return <br> year | Number of wild summer Chinook |  |  | Number of hatchery summer Chinook |  |  | Total M/F <br> ratio |

## Fecundity

Fecundities for the 2014-2016 returns of summer Chinook averaged 4,756, 4,982, and 4,423 eggs per female, respectively (Table 8.5). These values are less than the overall average of 5,112 eggs per female. Mean observed fecundities for the 2014-2016 returns were lower than the expected fecundities of $5,099,5,031$, and 4,902 eggs per female assumed in the broodstock collection protocols, respectively.
Table 8.5. Mean fecundity of wild, hatchery, and all female summer Chinook collected for broodstock in the Wenatchee River basin, 1989-2016; NA = not available.

### 8.2 Hatchery Rearing

## Rearing History

## Number of eggs taken

Based on the unfertilized egg-to-release survival standard of $81 \%$, a total of $1,066,667$ eggs were required to meet the program release goal of 864,000 smolts for brood years 1989-2011. An evaluation of the program in 2011 determined that 617,285 eggs are needed to meet the revised release goal of 500,001 smolts. This revised goal began with brood year 2012. From 1989 to 2011, the egg take goal was reached in seven of those years (Table 8.6). The egg takes from 2013-2016 were lower than the revised goal of 617,285 eggs.
Table 8.6. Numbers of eggs taken from Wenatchee summer Chinook broodstock, 1989-2015.

| Return year | Number of eggs taken |
| :---: | :---: |

## Number of acclimation days

The 2014 brood Wenatchee summer Chinook were transferred to the Dryden Acclimation Pond between 21 and 24 March 2016. These fish received 25-37 days of acclimation on Wenatchee River water before being volitionally released from 18-27 April 2016 (Table 8.7).

Table 8.7. Number of days Wenatchee summer Chinook were acclimated at Dryden Acclimation Pond, brood years 1989-2014. Numbers in parenthesis represents the number of days fish reared at Chiwawa Acclimation Facility.

| Brood year | Release year | Transfer date | Release date | Number of days |
| :---: | :---: | :---: | :---: | :---: |
| 1989 | 1991 | 2-Mar | 7-May | 66 |

## Release Information

## Numbers released

The 2014 Wenatchee summer Chinook program achieved $107.1 \%$ of the 500,001 goal with 535,255 fish being released in 2016 (Table 8.8). For brood years 2012-2014, the Wenatchee summer Chinook program has averaged $104 \%$ of the smolt obligation.
Table 8.8. Numbers of Wenatchee summer Chinook smolts released from the hatchery, brood years 19892014. Up to 2012, the release target for Wenatchee summer Chinook was 864,000 smolts. Beginning in 2012, the release target is 500,001 smolts.

## Numbers tagged

The 2014 brood Wenatchee summer Chinook were $96.4 \%$ CWT and adipose fin-clipped (Table 8.8).

In 2016, a total of 10,565 Wenatchee summer Chinook (brood year 2015) were tagged at Eastbank Hatchery on 19-22 September. These were tagged and released into raceway \#12. Fish were not fed during tagging or for two days before and after tagging. Fish averaged $84-86 \mathrm{~mm}$ in length and 6.1-6.5 g at time of tagging.

An additional 10,429 Wenatchee summer Chinook were tagged at Eastbank Hatchery on 10-13 October 2016. These were tagged and released into water-reuse circular ponds \#1 and \#2. Fish were not fed during tagging or for two days before and after tagging. Fish averaged $90-95 \mathrm{~mm}$ in length and $7.5-7.8 \mathrm{~g}$ at time of tagging.

Table 8.9 summarizes the number of hatchery summer Chinook that have been PIT-tagged and released into the Wenatchee River.

Table 8.9. Summary of PIT-tagging activities for Wenatchee hatchery summer Chinook, brood years 20082014.

## Fish size and condition at release

About 535,255 summer Chinook from the 2014 brood were volitionally released from Dryden Acclimation Pond on 18-27 April 2016. Assessing size-target achievement from pre-release sampling was not practical because of size-target studies on the 2012 and 2013 brood years. However, since the program began, Wenatchee summer Chinook have not met the target length and CV values (Table 8.10). The target weight (fish/pound or FPP) of juvenile fish has been met occasionally (Table 8.10).
Table 8.10. Mean lengths (FL, mm), weight ( g and fish/pound), and coefficient of variation (CV) of Wenatchee summer Chinook smolts released from the hatchery, brood years 1989-2014; NA = not available. Size targets are provided in the last row of the table.

| Brood year | Release year | Fork length (cm) |  | Mean weight |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Mean | CV | Grams (g) | Fish/pound |
| 1989 | 1991 | 158 | 13.7 | 45.4 | 10 |

| Targets (2012-present) |  |  |  |  |  |

${ }^{a}$ For brood year 2012, the fish per pound (fpp) targets were 10 fpp and 15 fpp .

## Survival Estimates

Overall survival of the 2014 brood Wenatchee summer Chinook from green (unfertilized) egg to release was higher than the standard set for the program. This was in part because of a high survival at all stages (Table 8.11).
Table 8.11. Hatchery life-stage survival rates (\%) for Wenatchee summer Chinook, brood years 1989-2014. Survival standards or targets are provided in the last row of the table.

| Brood year | Collection to spawning |  | Unfertilized egg-eyed | $\begin{gathered} \text { Eyed } \\ \text { egg- } \\ \text { ponding } \end{gathered}$ | 30 d after ponding | $\begin{gathered} 100 \mathrm{~d} \\ \text { after } \\ \text { ponding } \end{gathered}$ | $\begin{aligned} & \text { Ponding } \\ & \text { to } \\ & \text { release } \end{aligned}$ | Transport to release | Unfertilized egg-release |

### 8.3 Disease Monitoring

Rearing of the 2014 brood Wenatchee summer Chinook was similar to previous years with fish being held on well water before being transferred to Dryden Acclimation Pond for final acclimation in March 2016. Fish were transferred to Dryden Acclimation Pond from 21-24 March. Increased mortality caused by external fungus began to occur during the acclimation period at Dryden Acclimation Pond at which time a formalin treatment for 21 days was initiated to prevent the fungus from proliferating.
Results of the 2016 adult broodstock bacterial kidney disease (BKD) monitoring indicated that all females (100\%) had ELISA values less than 0.199. Additionally, all females had ELISA values less than 0.120 , which means that none of the progeny needed to be reared at densities less than 0.06 fish per pound (Table 8.12).

Table 8.12. Proportion of bacterial kidney disease (BKD) titer groups for the Wenatchee summer Chinook broodstock, brood years 1997-2016. Also included are the proportions to be reared at either 0.125 fish per pound or 0.060 fish per pound.

| Brood year ${ }^{\text {a }}$ | Optical density values by titer group |  |  |  | Proportion at rearing densities (fish per pound, fpp) ${ }^{\text {b }}$ |  |

| Average | 0.8772 | 0.0432 | 0.0291 | 0.0501 | 0.9043 | 0.0957 |
| Median | 0.9588 | 0.0139 | 0.0022 | 0.0140 | 0.9694 | 0.0306 |

${ }^{\text {a }}$ Individual ELISA samples were not collected before the 1997 brood.
${ }^{\mathrm{b}}$ ELISA values from broodstock BKD testing dictate what density the progeny of the broodstock are reared. Progeny of broodstock with high ELISA values are reared at lower density.

### 8.4 Natural Juvenile Productivity

During 2016, juvenile summer Chinook were sampled at the Lower Wenatchee Trap located near the town of Cashmere. The Lower Wenatchee Trap was moved to its present location in 2013 and as a result flow efficiency models need to be created and updated. These relationships continue to be developed and improved.

## Emigrant Estimates

## Lower Wenatchee Trap

The Lower Wenatchee Trap operated between 29 January and 26 July 2016. During that time, the trap was inoperable for 23 days because of high and low river discharge, debris, elevated river temperatures, large hatchery releases, and mechanical issues. During the sampling period, a total of 27,407 wild subyearling Chinook were captured at the Lower Wenatchee Trap. Based on 22 capture efficiencies, a significant relationship between trap efficiency and river discharge was created $\left(\mathrm{R}^{2}=0.56, P<0.040\right)$ and an estimate of $4,023,310( \pm 676,633 ; 95 \% \mathrm{CI})$ wild subyearling Chinook passed the trap within the sampling period (Table 8.13).

Table 8.13. Numbers of redds and juvenile summer Chinook emigrants in the Wenatchee River basin for brood years 1999-2015; NS = not sampled. From 2000-2010 the trap operated at Monitor; from 2013 to present the trap operated near Cashmere.

| Brood year | Number of redds | Egg deposition | Number of emigrants <br> upstream from trap | Total number of <br> emigrants |

| Median | $\mathbf{2 , 9 5 3}$ | $\mathbf{1 6 , 1 8 4 , 3 4 3}$ | $\mathbf{9 , 3 9 7 , 0 4 4}$ | $\mathbf{9 , 6 8 5 , 5 9 1}$ |

A total of 114 summer Chinook redds were observed downstream from the trap in 2016. Thus, the total number of summer Chinook emigrating from the Wenatchee River in 2015 was expanded using the ratio of the number of redds downstream from the trap to the number upstream from the trap. This resulted in a total summer Chinook emigrant estimate of 4,199,697 fish (Table 8.13). Most of the fish emigrated during April with another pulse in June (Figure 8.1). Monthly captures and mortalities of all fish collected at the Lower Wenatchee Trap are reported in Appendix B.

Figure 8.1. Numbers of wild subyearling Chinook captured at the Lower Wenatchee Trap during late January through July 2016.

Subyearling summer Chinook sampled in 2016 averaged 53 mm in length, 2.0 g in weight, and had a mean condition of 1.34 (Table 8.14). These size estimates were similar to the overall mean of subyearling summer Chinook sampled in previous years (overall means: $49 \mathrm{~mm}, 1.6 \mathrm{~g}$, and condition of 1.28).
Table 8.14. Mean fork length ( mm ), weight ( g ), and condition factor of subyearling summer Chinook collected in the Lower Wenatchee Trap, 2000-2016; NS = not sampled. From 2000-2010 the trap operated at Monitor; from 2013 to present the trap operated near Cashmere. Numbers in parentheses indicate 1 standard deviation.

${ }^{\text {a }}$ Sample size represents the number of fish that were measured for both length and weight.

### 8.5 Spawning Surveys

Surveys for Wenatchee summer Chinook redds were conducted from 5 September to 11 November 2016 in the Wenatchee River and Icicle Creek.

## Redd Counts

A total count of summer Chinook redds was estimated in 2016 based on weekly census surveys conducted in the Wenatchee River. Redds were counted in Icicle Creek when feasible. A total of 2,797 summer Chinook redds were counted in the Wenatchee River basin in 2016 (Table 8.15).
In the future, spawning escapement estimates may be derived using the area-under-the-curve (AUC) method described in Millar et al. (2012). WDFW now has three years of data (2014, 2015, and 2016) to inform model parameters (e.g., observer efficiency of redd counts at variable temporal and spatial scales). Model calibration has begun with existing data. After the conclusion of 2018 surveys, WDFW will have a complete model to generate updated spawning escapements with associated variance.

Table 8.15. Numbers of redds counted in the Wenatchee River basin, 1989-2016; ND = no data. From 1989-2013, numbers of redds were based on expanding "peak counts" to generate a Total Count. Since 2014, numbers of redds were based on weekly census surveys that encompass all reaches.

| Survey year | Redd counts |  | Total count |

|  | Median |  |  |

## Redd Distribution

Summer Chinook redds were not evenly distributed among reaches within the Wenatchee River basin in 2016 (Table 8.16; Figure 8.2). Most of the spawning occurred upstream from the Leavenworth Bridge in Reaches 6, 9, and 10. The highest density of redds occurred in Reach 6 near the confluence of the Icicle River.

Table 8.16. Total numbers of summer Chinook redds counted in different reaches in the Wenatchee River basin during September through mid-November 2016. Reach codes are described in Table 2.10.

| Survey reach | Total redd count |
| :---: | :---: |
| Wenatchee $1(\mathrm{~W} 1)$ | 1 |
| Wenatchee $2(\mathrm{~W} 2)$ | 144 |
| Wenatchee $3(\mathrm{~W} 3)$ | 224 |
| Wenatchee $4(\mathrm{~W} 4)$ | 41 |
| Wenatchee $5(\mathrm{~W} 5)$ | 103 |
| Wenatchee $6(\mathrm{~W} 6)$ | 687 |
| Wenatchee $7(\mathrm{~W} 7)$ | 192 |
| Wenatchee $8(\mathrm{~W} 8)$ | 309 |
| Wenatchee $9(\mathrm{~W} 9)$ | 502 |
| Wenatchee $10(\mathrm{~W} 10)$ | 522 |

| Survey reach | Total redd count |
| :---: | :---: |
| Icicle Creek (I1) | 72 |
| Totals | 2,797 |

## Wenatchee Summer Chinook Redds

Figure 8.2. Percent of the total number of summer Chinook redds counted in different reaches in the Wenatchee River basin during September through early-November 2016. Reach codes are described in Table 2.10.

## Spawn Timing

In 2016, spawning in the Wenatchee River began during the fourth week of September, peaked the first week of October, and ended the first week of November (Figure 8.3).

## Wenatchee Summer Chinook

Figure 8.3. Number of new summer Chinook redds counted during different weeks in the Wenatchee River, September through mid-November 2016.

## Spawning Escapement

Spawning escapement for Wenatchee summer Chinook was calculated as the total number of redds (expanded peak counts for return years 1989-2013) times the fish per redd ratio estimated from broodstock and fish sampled at adult trapping sites. ${ }^{25}$ The estimated fish per redd ratio for summer Chinook in 2016 was 2.11. Multiplying this ratio by the number of redds counted in the Wenatchee River basin resulted in a total spawning escapement of 5,902 summer Chinook (Table 8.17). This is less than the overall average spawning escapement of 9,100 summer Chinook.
Table 8.17. Spawning escapements for summer Chinook in the Wenatchee River basin, return years 1989-2016. Number of redds is based on expanded peak redd counts for the period 1989-2013.

| Return year | Fish/Redd | Redds | Total spawning <br> escapement |
| :---: | :---: | :---: | :---: |

### 8.6 Carcass Surveys

Surveys for Wenatchee summer Chinook carcasses were conducted from mid-September to early November 2016 in the Wenatchee River and Icicle Creek.

## Number sampled

A total of 1,309 summer Chinook carcasses were sampled during early September through early November in the Wenatchee River basin in 2016 (Table 8.18).
Table 8.18. Numbers of summer Chinook carcasses sampled within each survey reach in the Wenatchee River basin, 1993-2016. Reach codes are described in Table 2.10.

| Survey year | Number of summer Chinook carcasses |  |  |  |  |  |  |  |  |  |  |  |

## Carcass Distribution and Origin

Summer Chinook carcasses were not evenly distributed among reaches within the Wenatchee River basin in 2016 (Table 8.18; Figure 8.4). Most of the carcasses in the Wenatchee River basin were found upstream from the Leavenworth Bridge. The highest percentage of carcasses (37.8\%) was sampled in Reach 6.

## Wenatchee Summer Chinook Carcasses

Figure 8.4. Percent of summer Chinook carcasses sampled within different reaches in the Wenatchee River basin during September through mid-November 2016. Reach codes are described in Table 2.10.

As in previous years, regardless of origin, most summer Chinook were found in Reach 6 (Leavenworth Bridge to Icicle Road Bridge) (Table 8.19). In general, a larger percentage of wild fish were found in the upper reaches than were hatchery fish (Figure 8.5). In contrast, a larger percentage of hatchery fish were found in reaches downstream from the Icicle Road Bridge.
Table 8.19. Numbers of wild and hatchery summer Chinook carcasses sampled within different reaches in the Wenatchee River basin, 1993-2016.

| Survey year | Origin | Survey reach |  |  |  |  |  |  |  |  |  |  | Total |

## Wenatchee Summer Chinook

Figure 8.5. Distribution of wild and hatchery produced carcasses in different reaches in the Wenatchee River basin, 1993-2016. Reach codes are described in Table 2.10.

## Sampling Rate

If spawning escapement is based on total numbers of redds, then about $22 \%$ of the total spawning escapement of summer Chinook in the Wenatchee River basin was sampled in 2016 (Table 8.20). Sampling rates among survey reaches varied from 7 to $332 \%$.

Table 8.20. Number of redds and carcasses, total spawning escapement, and sampling rates for summer Chinook in the Wenatchee River basin, 2016.

| Sampling reach | Total number of <br> redds | Total number of <br> carcasses | Total spawning <br> escapement | Sampling rate |

| Icicle Creek (I1) | $62.0(0)$ | $75.3(2.6)$ |
| Total | $\mathbf{6 8 . 2 ~ ( 8 . 3 )}$ | $\mathbf{6 9 . 5}(4.9)$ |

### 8.7 Life History Monitoring

Life history characteristics of Wenatchee summer Chinook were assessed by examining carcasses on spawning grounds and fish collected or examined at broodstock collection sites, and by reviewing tagging data and fisheries statistics.

## Migration Timing

Migration timing of hatchery and wild Wenatchee summer Chinook was determined from broodstock data and stock assessment data collected at Dryden Dam. Sampling at Dryden Dam occurs from early July through mid-October. On average, during the early part of the migration, hatchery summer Chinook arrived about two weeks later than wild Chinook (Table 8.22). This pattern carried through the migration distribution of summer Chinook at Dryden Dam. By the end of the migration, hatchery fish passed Dryden Dam about two weeks after $90 \%$ of the wild fish passed the dam.

Table 8.22. The week that $10 \%, 50 \%$ (median), and $90 \%$ of the wild and hatchery summer Chinook salmon passed Dryden Dam, 2007-2016. The average week is also provided. Migration timing is based on collection of summer Chinook broodstock at Dryden Dam.

| Survey year | Origin | Wenatchee Summer Chinook Migration Time (week) |  |  |  | Sample size |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | 10 Percentile | 50 Percentile | 90 Percentile | Mean |  |

| Median | Wild | 29 | 31 | 38 | 32 | 405 |
|  | Hatchery | 29 | 34 | 41 | 35 | 322 |

## Age at Maturity

Because hatchery summer Chinook are released after one year of rearing and natural-origin summer Chinook migrate primarily as age-0 fish, total ages will differ between hatchery and natural-origin Chinook (see Hillman et al. 2011). Therefore, in this section, we evaluated age at maturity by comparing differences in salt (ocean) ages between the two groups.

Most of the wild and hatchery summer Chinook sampled during the period 1993-2016 in the Wenatchee River basin were salt age-3 fish (Table 8.23; Figure 8.6). Over the survey years, a higher percentage of salt age- 4 wild Chinook returned to the basin than did salt age-4 hatchery Chinook. In contrast, a higher proportion of salt age- 1 and 2 hatchery fish returned than did salt age- 1 and 2 wild fish. Thus, a higher percentage of wild fish returned at an older age than did hatchery fish.

Table 8.23. Proportions of wild and hatchery summer Chinook of different salt (ocean) ages sampled on spawning grounds in the Wenatchee River basin, 1993-2016.

| Sample year | Origin | Salt age |  |  |  |  | Sample size |

## Wenatchee Summer Chinook

Figure 8.6. Proportions of wild and hatchery summer Chinook of different salt (ocean) ages sampled at broodstock collection sites and on spawning grounds in the Wenatchee River basin for the combined years 1993-2016.

## Size at Maturity

On average, hatchery summer Chinook were about 4 cm smaller than wild summer Chinook sampled in the Wenatchee River basin (Table 8.24). This is likely because a higher percentage of hatchery fish returned as salt age- 2 and 3 fish than did wild fish. In contrast, a higher percentage of wild fish returned as salt age-4 fish than did hatchery fish. Analyses for the five-year reports will compare sizes of hatchery and wild fish of the same age groups and sex.
Table 8.24. Mean lengths ( $\mathrm{POH} ; \mathrm{cm}$ ) and variability statistics for wild and hatchery summer Chinook sampled in the Wenatchee River basin, 1993-2016; SD = 1 standard deviation.

## Contribution to Fisheries

Most of the harvest on hatchery-origin Wenatchee summer Chinook occurred in the ocean (Table 8.25). Ocean harvest has made up $47 \%$ to $100 \%$ of all hatchery Wenatchee summer Chinook harvested. Total harvest on early brood years (1990-1996 and 2007) was lower than for brood years 1997-2010.
Table 8.25. Estimated number and percent (in parentheses) of hatchery-origin Wenatchee summer Chinook captured in different fisheries, brood years 1989-2010.

## Straying

Stray rates were determined by examining CWTs recovered on spawning grounds within and outside the Wenatchee River basin. Targets for strays based on return year (recovery year) within the upper Columbia River basin (Priest Rapids Dam to Chief Joseph Dam) should be less than $10 \%$ and targets for strays outside the upper Columbia River should be less than 5\%. The target for brood year stay rates should be less than $5 \%$.

Hatchery-origin Wenatchee summer Chinook have strayed into the Entiat, Chelan, Methow, and Okanogan River basins and onto the Hanford Reach (Table 8.26). In only one year did Wenatchee summer Chinook strays make up more than $10 \%$ of the spawning escapement in the Chelan Tailrace. They made up more than $10 \%$ of the spawning escapement in the Entiat River basin in five different years. They made up less than $10 \%$ of the spawning escapements in the Methow and Okanogan River basins and the Hanford Reach.

Table 8.26. Number and percent of spawning escapements within other non-target spawning streams within the upper Columbia River basin that consisted of hatchery-origin Wenatchee summer Chinook, return years 1994-2015. For example, for return year 2000, $3 \%$ of the summer Chinook escapement in the Methow River basin consisted of hatchery-origin Wenatchee summer Chinook. Percent strays should be less than $10 \%$.

| 2013 | 252 | 7.0 | 57 | 0.7 | 2 | 0.1 | 8 | 1.1 | 0 | 0.0 |
| 2014 | 15 | 0.9 | 0 | 0.0 | 4 | 0.4 | 12 | 2.2 | 0 | 0.0 |
| 2015 | 75 | 1.9 | 13 | 0.1 | 4 | 0.3 | 12 | 2.9 | 0 | 0.0 |
| Average | 102 | 4.1 | 24 | 0.4 | 24 | 3.5 | 30 | 6.4 | 3 | 0.0 |
| Median | 94 | 3.7 | 13 | 0.2 | 11 | 3.0 | 14 | 4.0 | 0 | 0.0 |

Based on brood year analyses, on average, about $10 \%$ of the hatchery-origin Wenatchee summer Chinook returns have strayed into non-target populations, exceeding the target of 5\% (Table 8.27). Depending on brood year, percent strays into non-target spawning areas have ranged from 0-20\%. In addition, on average, about $7 \%$ have strayed into non-target hatchery programs.

Table 8.27. Number and percent of hatchery-origin Wenatchee summer Chinook that homed to target spawning areas and the target hatchery program, and number and percent that strayed to non-target spawning areas and non-target hatchery programs, by brood years 1989-2010. Percent stays should be less than 5\%.

* Homing to the target hatchery includes Wenatchee hatchery summer Chinook that are captured and included as broodstock in the Wenatchee Hatchery program. These hatchery fish are typically collected at Dryden and Tumwater dams.

## Genetics

Genetic studies were conducted in 2011 to investigate relationships among temporally replicated collections of summer Chinook from the Wenatchee River, Methow River, and Okanogan River in the upper Columbia River basin (Kassler et al. 2011; the entire report is appended as Appendix N ). A total of 2,416 summer Chinook were collected from tributaries in the upper Columbia River basin. Two collections of natural-origin summer Chinook from 1993 (prior to the supplementation program) were taken from the Wenatchee River basin $(\mathrm{N}=139)$ and compared to collections of
hatchery and natural-origin Chinook from 2006 and 2008 ( $\mathrm{N}=380$ ). Two pre-supplementation collections from the Methow River (1991 and 1993) were compared to supplementation collections from 2006 and $2008(\mathrm{~N}=362)$. Three pre-supplementation collections from the Okanogan River Basin (1991, 1992, and 1993) were compared with supplementation collections from 2006 and $2008(\mathrm{~N}=669)$. A collection of natural-origin summer Chinook from the Chelan River was also analyzed ( $\mathrm{N}=70$ ). Additionally, hatchery collections from Eastbank Hatchery (Wenatchee and Methow/Okanogan stock; $\mathrm{N}=221$ ) and Wells Hatchery $(\mathrm{N}=294)$ were analyzed and compared to the in-river collections. Summer Chinook data (provided by the USFWS) from the Entiat River $(\mathrm{N}=190)$ were used for comparison. Lastly, data from eight collections of fall Chinook ( $\mathrm{N}=2,408$ ) were compared to the collections of summer Chinook. Samples of natural and hatchery-origin summer Chinook were analyzed and compared to determine if the supplementation programs have affected the genetic structure of these populations. The study also calculated the effective number of breeders for collection locations of natural and hatchery-origin summer Chinook from 1993 and 2008.

In general, population differentiation was not observed among the temporally replicated collection locations. A single collection from the Okanogan River (1993) was the only collection showing statistically significant differences. The effective number of breeders was not statistically different from the early collection in 1993 in comparison to the late collection in 2008. Overall, these analyses revealed a lack of differentiation among the temporal replicates from the same locations and among the collection from different locations, suggesting the populations have been homogenized or that there has been substantial gene flow among populations. Additional comparisons among summer-run and fall-run Chinook populations in the upper Columbia River were conducted to determine if there was any differentiation between Chinook with different run timing. These analyses revealed pairwise $\mathrm{F}_{\text {ST }}$ values that were less than 0.01 for the collections of summer Chinook to collections of fall Chinook from Hanford Reach, lower Yakima River, Priest Rapids, and Umatilla. Collections of fall Chinook from Crab Creek, Lyons Ferry Hatchery, Marion Drain, and Snake River had pairwise FST values that were higher in comparison to the collections of summer Chinook. The consensus clustering analysis did not provide good statistical support to the groupings, but did show relationships among collections based on geographic proximity. Overall the summer and fall run Chinook that have historically been spawned together were not differentiated while fall Chinook from greater geographic distances were differentiated.
It is important to note that no new information will be reported on genetics until the next five-year report (2018).

## Proportionate Natural Influence

Another method for assessing the genetic risk of a supplementation program is to determine the influence of the hatchery and natural environments on the adaptation of the composite population. This is estimated by the proportion of natural-origin fish in the hatchery broodstock ( pNOB ) and the proportion of hatchery-origin fish in the natural spawning escapement (pHOS). We calculated Proportionate Natural Influence (PNI) by iterating Ford's (2002) equations 5 and 6 to equilibrium, using a heritability of 0.3 and a selection strength of three standard deviations. The larger the PNI value, the greater the strength of selection in the natural environment relative to that of the hatchery environment. For the natural environment to dominate selection, PNI should be greater than 0.50 , and important integrated populations should have a PNI of at least 0.67 (HSRG/WDFW/NWIFC 2004).

For all brood years the PNI value has been greater than or equal to 0.67 (Table 8.28). This suggests that the natural environment has a greater influence on adaptation of Wenatchee summer Chinook than does the hatchery environment.

Table 8.28. Proportionate Natural Influence (PNI) values for the Wenatchee summer Chinook supplementation program for brood years 1989-2015. NOS = number of natural-origin Chinook on the spawning grounds; HOS = number of hatchery-origin Chinook on the spawning grounds; $\mathrm{NOB}=$ number of natural-origin Chinook collected for broodstock; and $\mathrm{HOB}=$ number of hatchery-origin Chinook included in hatchery broodstock.

| Average | 8,020 | 1,198 | 0.14 | 303 | 33 | 0.92 | 0.87 |
| Median | 7,431 | 1,229 | 0.14 | 290 | 5 | 0.99 | 0.87 |

${ }^{\text {a }}$ PNI was calculated previously using PNI approximate equation 11 (HSRG 2009; their Appendix A). All PNI values presented here were recalculated by iterating Ford's (2002) equations 5 and 6 to equilibrium using a heritability of 0.3 and a selection strength of three standard deviations. C. Busack, NOAA Fisheries, 21 March 2016, provided the model for calculating PNI.

## Post-Release Survival and Travel Time

We used PIT-tagged fish to estimate survival rates and travel time (arithmetic mean days) of hatchery summer Chinook from the Wenatchee River release site to McNary Dam, and smolt to adult ratios (SARs) from release to detection at Bonneville Dam (Table 8.29). ${ }^{26}$ Over the six brood years for which PIT-tagged hatchery fish were released, survival rates from the Wenatchee River to McNary Dam ranged from 0.619 to 0.910 ; SARs from release to detection at Bonneville Dam ranged from 0.001 to 0.017 . Average travel time from the Wenatchee River to McNary Dam ranged from 11 to 29 days.

Most of the variation in survival rates and travel time resulted from releases of different experimental groups (Table 8.29). For example, brood year 2009 was split into three groups (control raceway group, long-term recirculating aquaculture system (RAS) group (R1), and shortterm RAS group (R2)). In this case, the control group appeared to have a higher survival rate but a longer travel time from release to McNary Dam than did the two treatment groups. SARs varied little among the three groups.

Another experiment was conducted with brood years 2012 and 2013. These brood years were split into four different treatment groups (small-size fish in raceway, large-size fish in raceway, smallsize fish in RAS, and large-size fish in RAS). Although the number of replicates is small, releases from the RAS had higher survival rates to McNary Dam and faster travel times. Large-size fish from the RAS had the highest survival rates and fastest travel times.

Table 8.29. Total number of Wenatchee hatchery summer Chinook released with PIT tags, their survival and travel times (mean days) to McNary Dam, and smolt-to-adult (SAR) ratios for brood years 2008-2014. Standard errors are shown in parentheses. $\mathrm{RAS}=$ recirculating aquaculture system; NA $=$ not available (i.e., not all the fish from the release groups have returned to the Columbia River).

## Natural and Hatchery Replacement Rates

Natural replacement rates (NRR) were calculated as the ratio of natural-origin recruits (NOR) to the parent spawning population (spawning escapement). Natural-origin recruits are naturally produced (wild) fish that survive to contribute to harvest (directly or indirectly), to broodstock, and to spawning grounds. We do not account for fish that died in route to the spawning grounds (migration mortality) or died just before spawning (pre-spawn mortality) (see Appendix B in Hillman et al. 2012). We calculated NORs with and without harvest. NORs without harvest include all returning fish that either returned to the basin or were collected as wild broodstock. NORs with harvest include all fish harvested and are based on brood year harvest rates from the hatchery program. For brood years 1989-2009, NRR for summer Chinook in the Wenatchee averaged 0.98 (range, 0.15-2.95) if harvested fish were not included in the estimate and 2.60 (range, 0.33-9.55) if harvested fish were included in the estimate (Table 8.30). NRRs for more recent brood years will be calculated as soon as all tag recoveries and sampling rates have been loaded into the database.

Hatchery replacement rates (HRR) are the hatchery adult-to-adult returns and were calculated as the ratio of hatchery-origin recruits (HOR) to the parent broodstock collected. These rates should be greater than the NRRs and greater than or equal to 5.7 (the calculated target value in Hillman et al. 2013). The target value of 5.7 includes harvest. HRRs exceeded NRRs in 16 of the 21 years of data, regardless if harvest was or was not included in the estimate (Table 8.30). Hatchery replacement rates for Wenatchee summer Chinook have exceeded the estimated target value of 5.7 in 10 of the 21 years of data.
Table 8.30. Broodstock collected, spawning escapements, natural and hatchery-origin recruits (NOR and HOR), and natural and hatchery replacement rates (NRR and HRR; with and without harvest) for summer Chinook in the Wenatchee River basin, brood years 1989-2009.

## Smolt-to-Adult Survivals

Smolt-to-adult survival ratios (SARs) were calculated as the number of hatchery adult recaptures divided by the number of tagged hatchery smolts released. Here, SARs were based on CWT returns. For the available brood years, SARs have ranged from 0.00037 to 0.01562 for hatchery summer Chinook in the Wenatchee River basin (Table 8.31).
Table 8.31. Smolt-to-adult ratios (SARs) for Wenatchee hatchery summer Chinook, brood years 19892010.

| Brood year | Number of tagged smolts <br> released $^{\mathrm{a}}$ | Estimated adult <br> captures $^{\mathbf{b}}$ | SAR |
| :---: | :---: | :---: | :---: |
| 1989 | 144,905 | 1,027 | 0.00709 |

| Median | $\mathbf{6 3 5 , 4 3 7}$ | $\mathbf{2 , 4 3 0}$ | $\boldsymbol{0 . 0 0 4 1 4}$ |

${ }^{\text {a }}$ Includes all tag codes and CWT released fish (CWT + Ad Clip fish and CWT-only fish).
${ }^{\mathrm{b}}$ Includes estimated recoveries (spawning ground, hatcheries, harvest, etc.) and observed recoveries if estimated recoveries were unavailable.

### 8.8 ESA/HCP Compliance

## Broodstock Collection

Per the 2014 broodstock collection protocol, 278 natural-origin (adipose fin present) summer Chinook adults were targeted for collection at Dryden and Tumwater dams. The actual 2014 collection totaled 281 summer Chinook ( 279 natural-origin and two hatchery-origin; the hatcheryorigin fish were not direct collections but rather adipose-present non-wired fish with a hatchery scale pattern) in combination from Dryden and Tumwater dams. Trapping began 23 June and ended 24 September2014.
Summer Chinook and steelhead broodstock collections occurred concurrently at Dryden Dam. Thus, steelhead and spring Chinook encounters at Dryden Dam during Wenatchee summer Chinook broodstock collection were attributable to steelhead broodstock collections authorized under ESA Permit 1395 take authorizations. No steelhead or spring Chinook takes were associated with the Wenatchee summer Chinook collection. No bull trout were encountered during summer Chinook broodstock collection at Dryden Dam in 2014.

Consistent with impact minimization measures in ESA Permit 1347, all ESA-listed species handled during summer Chinook broodstock collection were subject to water-to-water transfers or anesthetized if removed from the water during handling.

## Hatchery Rearing and Release

The 2014 Wenatchee summer Chinook program released an estimated 535,255 smolts, representing $107.1 \%$ of the 500,001-programmed production, and was within the $110 \%$ overage allowance identified in ESA permit 1347.

## Hatchery Effluent Monitoring

Per ESA Permits $1196,1347,1395,18118,18120$, and 18121, permit holders shall monitor and report hatchery effluents in compliance with applicable National Pollution Discharge Elimination Systems (NPDES) (EPA 1999) permit limitations. There were no NPDES violations reported at PUD Hatchery facilities during the period 1 January through 31 December 2016. NPDES monitoring and reporting for Chelan PUD Hatchery Programs during 2016 are provided in Appendix F.

## Smolt and Emigrant Trapping

ESA-listed spring Chinook and steelhead were encountered during operation of the Lower Wenatchee Trap. ESA takes are reported in the steelhead (Section 3.8) and spring Chinook (Section 5.8) sections and are not repeated here.

## Spawning Surveys

Summer Chinook spawning ground surveys conducted in the Wenatchee River basin during 2016 were consistent with ESA Section 10 Permit No. 1347. Because of the difficulty of quantifying the level of take associated with spawning ground surveys, the Permit does not specify a take level associated with these activities, even though it does authorize implementation of spawning ground surveys. Therefore, no take levels are reported. However, to minimize potential effects to established redds, wading was restricted to the extent practical, and extreme caution was used to avoid established redds when wading was required.

## SECTION 9: METHOW SUMMER CHINOOK

The original goal of summer Chinook salmon supplementation in the Methow Basin was in part to use artificial production to replace adult production lost because of mortality at Wells, Rocky Reach, and Rock Island dams ${ }^{27}$, while not reducing the natural production or long-term fitness of summer Chinook in the basin. The Rock Island Fish Hatchery Complex began operation in 1989 under funding from Chelan PUD. The Complex operated originally through the Rock Island Settlement Agreement, but since 2004 has operated under the Anadromous Fish Agreement and Habitat Conservation Plans. Beginning with broodstock collection in 2012, Grant PUD took over the summer Chinook salmon supplementation program in the Methow River basin. Grant PUD constructed a new overwinter acclimation facility adjacent to the Carlton Acclimation Pond and the first fish released from this facility was 2014. The first fish that were overwinter acclimated in the facility were released in 2015. The new facility includes eight, 30 -foot diameter dual-drain circular tanks.

Presently, adult summer Chinook are collected for broodstock from the run-at-large at the westladder trapping facility at Wells Dam. Before 2012, the goal was to collect up to 222 natural-origin adult summer Chinook for the Methow program. In 2011, the Hatchery Committees reevaluated that amount of hatchery compensation needed to achieve NNI. Based on that evaluation, the goal of the program was revised. The current goal (beginning in 2012) is to collect up to 102 naturalorigin summer Chinook for the Methow program. Broodstock collection occurs from about 1 July through 15 September with trapping occurring no more than 16 hours per day, three days a week. If natural-origin broodstock collection falls short of expectation, hatchery-origin adults can be collected to make up the difference.
Adult summer Chinook are spawned and reared at Eastbank Fish Hatchery. Juvenile summer Chinook were transferred from the hatchery to Carlton Acclimation Pond in March until overwinter acclimation was initiated with the 2013 brood year. They are now transferred to the Carlton Acclimation Facility in October or November and released from the new facility in late April to early May.

Before 2012, the production goal for the Methow summer Chinook supplementation program was to release 400,000 yearling smolts into the Methow River at ten fish per pound. Beginning with the 2012 brood, the revised goal is to release 200,000 yearling smolts at 15 fish per pound. Targets for fork length and weight are $163 \mathrm{~mm}(\mathrm{CV}=9.0)$ and 45.4 g , respectively. Over $90 \%$ of these fish are marked with CWTs. In addition, since 2009, juvenile summer Chinook have been PIT tagged annually.

### 9.1 Broodstock Sampling

This section focuses on results from sampling 2014-2016 Methow summer Chinook broodstock that were collected in the West Ladder of Wells Dam.

[^24]
## Origin of Broodstock

Broodstock collected in 2014, 2015, and 2016 consisted almost entirely of natural-origin (adipose fin present) summer Chinook (Table 9.1).
Table 9.1. Numbers of wild and hatchery summer Chinook collected for broodstock, numbers that died before spawning, and numbers of Chinook spawned for the Methow/Okanogan programs during 19892011. Numbers of broodstock collected from 2012 to present are only for the Methow summer Chinook Program. Unknown origin fish (i.e., undetermined by scale analysis, no CWT or fin clips, and no additional hatchery marks) were considered naturally produced. Mortality includes fish that died of natural causes typically near the end of spawning and were not needed for the program and surplus fish killed at spawning.

| Brood year | Wild summer Chinook |  |  |  |  | Hatchery summer Chinook |  |  |  |  | Total number spawned |

${ }^{\text {a }}$ Pre-spawn loss represents the number of fish that died during the holding period before spawning. Mortality is the number of fish that were surplused following spawning.
${ }^{\mathrm{b}}$ Number of fish spawned and collected during these years included fish retained from the right- and left-bank ladder traps at Wells Dam and fish collected from the volunteer channel. There was no distinction made between fish collected at trap locations and program (i.e., aggregated population used for Wells, Methow, and Okanogan summer Chinook programs).
${ }^{\text {c }}$ The average and median represent broodstock collected for the combined Methow and Okanogan programs. Because of bias from aggregating the spawning population from 1989-1993, averages are based on adult numbers collected from 1994-2011.
${ }^{\mathrm{d}}$ The average and median represent broodstock collected only for the Methow program.

## Age/Length Data

Ages of summer Chinook broodstock were determined from analysis of scales and/or CWTs. Broodstock collected from the 2014 return consisted primarily of age-4 and 5 natural-origin Chinook ( $95.8 \%$ ). Age-3 natural-origin fish made up $4.1 \%$ of the broodstock (Table 9.2).

Broodstock collected from the 2015 return consisted primarily of age-4 and 5 natural-origin Chinook ( $87.8 \%$ ). Age-3 natural-origin Chinook made up $12.2 \%$ of the broodstock (Table 9.2).

Broodstock collected from the 2016 return consisted primarily of age- 4 and 5 natural-origin Chinook ( $97.8 \%$ ). Age-3 natural-origin Chinook made up $1.1 \%$ of the broodstock (Table 9.2).
Table 9.2. Percent of hatchery and wild summer Chinook of different ages (total age) collected from broodstock for the Methow/Okanogan programs, 1991-2016.

Mean lengths of natural-origin summer Chinook of a given age differed little among return years 2014-2016 (Table 9.3). For 2015, average fork lengths for age-4 natural-origin adults were 8 cm longer than that of age-4 hatchery fish (Table 9.3). There were no hatchery-origin adults collected for the 2014 and 2016 brood. Differences in hatchery-origin and natural-origin fish were hard to
assess given the small sample size of hatchery-origin fish (i.e., few hatchery fish were included in the broodstock).

Table 9.3. Mean fork length (cm) at age (total age) of hatchery and wild Methow/Okanogan summer Chinook collected from broodstock for the Methow/Okanogan programs, 1991-2016; $\mathrm{N}=$ sample size and $\mathrm{SD}=1$ standard deviation.

## Sex Ratios

Male summer Chinook in the 2014 broodstock made up about $50.0 \%$ of the adults collected, resulting in an overall male to female ratio of 1.00:1.00 (Table 9.4.). In 2015, males made up about $51.0 \%$ of the adults collected, resulting in an overall male to female ratio of 1.02:1.00 (Table 9.4). In 2016, males made up about $49 \%$ of the adults collected, resulting in an overall male to female ratio of 0.96:1.00 (Table 9.4). The ratios for 2014 and 2015 broodstock were above or at the assumed 1:1 ratio goal in the broodstock protocol.
Table 9.4. Numbers of male and female wild and hatchery summer Chinook collected for broodstock at Wells Dam for the Methow/Okanogan programs, 1991-2016. Ratios of males to females are also provided.

${ }^{a}$ Numbers and male to female ratios were derived from the aggregate population collected at Wells Fish Hatchery volunteer channel and left- and right-ladder traps at Wells Dam.
${ }^{\mathrm{b}}$ Total values were derived from 1994-present data to exclude aggregate population bias from 1989-1993 returns.

## Fecundity

Fecundities for the 2014, 2015, and 2016 summer Chinook broodstock averaged 4,685, 4,410, and 4,509 eggs per female, respectively (Table 9.5). These values are close to the overall average of 4,899 eggs per female. Mean observed fecundities for the 2014, 2015, and 2016 returns were below the expected fecundity of $4,982,4,861$, and 4,721 eggs per female assumed in the broodstock protocols, respectively.
Table 9.5. Mean fecundity of wild, hatchery, and all female summer Chinook collected for broodstock at Wells Dam for the Methow/Okanogan programs, 1989-2016; NA = not available.

### 9.2 Hatchery Rearing

## Rearing History

## Number of eggs taken

Based on the unfertilized egg-to-release survival standard of $81 \%$, a total of 493,827 eggs were needed to meet the program release goal of 400,000 smolts for brood years 1989-2011. An evaluation of the program in 2011 determined that 246,913 eggs are needed to meet the revised release goal of 200,000 smolts. This revised goal began with brood year 2012. From 1989 through 2011, the egg take goal was reached in eight of those years (Table 9.6). From 2012 to present, the egg take goal was not achieved (Table 9.6).

Table 9.6. Numbers of eggs taken from summer Chinook broodstock collected at Wells Dam for the Methow/Okanogan programs, 1989-2016.

| Return year | Number of eggs taken |
| :---: | :---: |
| 1989 | 482,800 |
| 1990 | 464,097 |

## Number of acclimation days

Improvements to Carlton Acclimation Pond made overwinter rearing feasible beginning with the 2013 brood Methow summer Chinook. Fish are held on well water at Eastbank Fish Hatchery before being transferred to Carlton Acclimation Pond for final acclimation on Methow River water
in October (Table 9.7). Only the 1994 and 1995 broods were reared for longer durations at the Methow Fish Hatchery on Methow River water.

Table 9.7. Number of days Methow summer Chinook were acclimated at Carlton Acclimation Pond, brood years 1989-2014.

| Brood year | Release year | Transfer date | Release date | Number of days |
| :---: | :---: | :---: | :---: | :---: |

## Release Information

## Numbers released

The 2014 brood Methow summer Chinook program achieved $83.3 \%$ of the 200,000 goal with about 167,616 Chinook being force released from the circular ponds on the night of 18 April 2016 (Table 9.8). Forced releases at night were initiated in 2016 to improve post-release survival.
Table 9.8. Numbers of Methow summer Chinook smolts released from the hatchery, brood years 19892014. Beginning with the 2014 release group (brood year 2012), the release target for Methow summer Chinook is 200,000 smolts.

| Brood year | Release year | CWT mark rate | Number of smolts released |
| :---: | :---: | :---: | :---: |
| 1989 | 1991 | 0.8529 | 420,000 |

## Numbers tagged

The 2014 brood Methow summer Chinook were $99 \%$ CWT and adipose fin-clipped (Table 9.8).
A total of 5,064 Methow summer Chinook (brood 2015) were PIT tagged at the Carlton Acclimation Facility on 27-29 March 2017. These fish were tagged in circular ponds \#1 through \#8. Fish were not fed during tagging or for two days before and after tagging. Fish averaged 130 mm in length and 28 g at time of tagging.
Table 9.9 summarizes the number of hatchery summer Chinook that have been PIT-tagged and released into the Methow River.

Table 9.9. Summary of PIT-tagging activities for Methow hatchery summer Chinook, brood years 20082014.

| Brood year | Release year | Number of fish <br> tagged | Number of <br> tagged fish that <br> died | Number of tags <br> shed | Number of <br> tagged fish <br> released |

## Fish size and condition at release

A forced release of yearling Chinook smolts took place on the night of 18 April 2016. Size at release from the acclimated fish was $76.7 \%$ and $50.8 \%$ of the respective target fork length and weight goals, respectively (Table 9.10). This brood year exceeded the target CV for length by $20 \%$.
Table 9.10. Mean lengths (FL, mm), weight ( g and fish/pound), and coefficient of variation (CV) of Methow summer Chinook smolts released from the hatchery, brood years 1991-2014. Size targets are provided in the last row of the table.

| Brood year | Release year | Fork length (mm) |  | Mean weight |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Mean | $\mathbf{C V}$ | Grams (g) | Fish/pound |

## Survival Estimates

Overall survival of the 2014 brood Methow summer Chinook from green (unfertilized) egg-torelease was below the standard set for the program (Table 9.11). This was largely because of lower eyed to ponding, ponding to release, and transport to release survivals.
Table 9.11. Hatchery life-stage survival rates (\%) for Methow summer Chinook, brood years 1989-2014. Survival standards or targets are provided in the last row of the table.

| Brood <br> year | Collection to <br> spawning |  | Unfertilized <br> egg-eyed | Eyed <br> egg- <br> ponding | $\mathbf{3 0 d}$ <br> after <br> ponding | $\mathbf{1 0 0 ~ d}$ <br> after <br> ponding | Ponding <br> to <br> release | Transport <br> to release | Unfertilized <br> egg-release |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 89.8 | 99.5 | 89.9 | 96.7 | 99.7 | 99.4 | 73.3 | 98.5 | 87.0 |
| $1990^{\mathrm{a}}$ | 93.9 | 99.0 | 84.9 | 97.1 | 81.2 | 80.6 | 97.7 | 99.5 | 84.4 |

${ }^{a}$ Survival rates were calculated from aggregate population collected at Wells Fish Hatchery volunteer channel and left- and rightladder traps at Wells Dam.
${ }^{\mathrm{b}}$ Survival rates were calculated from aggregate collections at Wells east fish ladder for the Methow and Okanogan/Similkameen programs. About $41 \%$ of the total fish collected were used to estimate survival rates.
${ }^{c}$ Survival rates were calculated from aggregate collections at Wells West Ladder for the Methow and Similkameen programs. About $71 \%$ of the total fish collected were used to estimate survival rates.

### 9.3 Disease Monitoring

Results of 2016 adult broodstock bacterial kidney disease (BKD) monitoring indicated that all females had ELISA values less than 0.120 (Table 9.12).

Table 9.12. Proportion of bacterial kidney disease (BKD) titer groups for the Methow/Okanogan summer Chinook broodstock, brood years 1997-2016. Also included are the proportions to be reared at either 0.125 fish per pound or 0.060 fish per pound.

${ }^{2}$ Individual ELISA samples were not collected before the 1997 brood.
${ }^{\mathrm{b}}$ ELISA values from broodstock BKD testing dictate what density the progeny of the broodstock are reared. Progeny of broodstock with high ELISA values are reared at lower density.

### 9.4 Natural Juvenile Productivity

During 2016, juvenile summer Chinook were sampled at the Methow Trap located near RM 18.6.
Trapping has occurred in this location since 2004.

## Emigrant Estimates

## Methow Trap

On the Methow River, WDFW used traps with cone diameters of 2.4 m and 1.5 m to increase trap efficiency over a greater range of river discharge. Large variation in discharge and channel configuration required the use of two trapping positions. The $1.5-\mathrm{m}$ trap was deployed in the lower position at discharges less than $45.3 \mathrm{~m}^{3} / \mathrm{s}$. At discharges greater than $45.3 \mathrm{~m}^{3} / \mathrm{s}$, the $2.4-\mathrm{m}$ trap was installed and operated in tandem with the 1.5 m trap.

A pooled-efficiency model estimated the total number of emigrants when the trap was operated in the low trapping position. A flow-efficiency model estimated the total number of emigrants when the trap was operated in the upper trapping position. The pooled-efficiency estimate was based on four mark-recapture release groups in 2016. The flow-efficiency estimate was based on 15 markrecapture release groups that were conducted over the period 2007-2016.
The Methow Trap operated at night between 19 February and 5 December 2016. During that time, the trap was inoperable for 17 days because of high river discharge. During the ten-month sampling period, a total of 6,512 wild subyearling summer Chinook were captured at the Methow Trap. Based on the pooled-efficiency model and the flow efficiency model, the total number of wild subyearling summer Chinook that emigrated past the Methow Trap in 2016 was 761,769 $( \pm 4,082,084)$ (Table 9.13). This value contains an estimated 49,126 fish that likely emigrated past the trapping location during the 17 days in which the trap was not operating. Because 462 summer Chinook redds were observed downstream from the trap in 2015, the total number of summer Chinook emigrating from the Methow River in 2016 was expanded using the ratio of the number of redds downstream from the trap to the number upstream from the trap. This resulted in a total summer Chinook emigrant estimate of $1,219,425( \pm 5,164,732)$ fish (Table 9.13). Most of these fish emigrated during April (Figure 9.1).

* Trap did not operate for entire migration period.

Figure 9.1. Numbers of wild subyearling Chinook captured at the Methow Trap during February to early December 2016.

Subyearling summer Chinook sampled in 2016 averaged 65.6 mm in length, 3.8 g in weight, and had a mean condition of 1.20 (Table 9.14). These size estimates were similar to the overall mean of subyearling summer Chinook sampled in previous years (overall means: $63.3 \mathrm{~mm}, 3.8 \mathrm{~g}$, and condition of 1.23). Environmental conditions at the trapping location do not allow for accurate weight measurements on fry (i.e., $<50 \mathrm{~mm}$ fork length), so this size class is underrepresented in the averages.
Table 9.14. Mean fork length (mm), weight (g), and condition factor of subyearling summer Chinook collected in the Methow Trap, 2004-2016. Numbers in parentheses indicate 1 standard deviation.

| Sample year | Sample size $^{\mathbf{a}}$ | Mean size |  |  |

${ }^{a}$ Sample size represents the number of fish that were measured for both length and weight.

### 9.5 Spawning Surveys

Surveys for Methow summer Chinook redds were conducted from late September to midNovember 2016 in the Methow River. Total redd counts (not peak counts) were conducted in the river (see Appendix O for more details).

## Redd Counts

A total of 1,115 summer Chinook redds were counted in the Methow River in 2016 (Table 9.15). This is greater than the overall average of 711 redds.

Table 9.15. Total number of redds counted in the Methow River, 1989-2016.

| Survey year | Total redd count |
| :---: | :---: |
| 1989 | $149^{*}$ |
| 1990 | $418^{*}$ |

| 2016 | 1,115 |
| Average | $\mathbf{7 1 1}$ |
| Median | $\mathbf{6 1 0}$ |

* Total counts based on expanded aerial counts.

## Redd Distribution

Summer Chinook redds were not evenly distributed among the seven reaches in the Methow River. Most redds ( $81 \%$ ) were located within the lower three reaches (downstream from Twisp) (Table 9.16; Figure 9.2). Few Chinook spawned upstream from Winthrop (Reaches 6 and 7).

Table 9.16. Total number of summer Chinook redds counted in different reaches on the Methow River during September through early November 2016. Reach codes are described in Table 2.11.

| Survey reach | Total redd count | Percent |
| :---: | :---: | :---: |
| Methow 1 (M1) | 182 | 16.3 |
| Methow 2 (M2) | 309 | 27.7 |
| Methow 3 (M3) | 410 | 36.8 |
| Methow 4 (M4) | 57 | 5.1 |
| Methow 5 (M5) | 147 | 13.2 |
| Methow 6 (M6) | 1 | 0.1 |
| Methow 7 (M7) | 9 | 0.8 |
| Totals | $\mathbf{1 , 1 1 5}$ | $\mathbf{1 0 0 . 0}$ |

## Methow Summer Chinook Redds

Figure 9.2. Percent of the total number of summer Chinook redds counted in different reaches on the Methow River during September through mid-November 2016. Reach codes are described in Table 2.11.

## Spawn Timing

Spawning in 2016 began the last week of September, peaked in early October, and ended the third week of November (Figure 9.3). Stream temperatures in the Methow River, when spawning began, varied from $10.5-11.0^{\circ} \mathrm{C}$. Peak spawning occurred during the first week of October in the upper reaches of the Methow River and one-two weeks later in the lower reaches.

Figure 9.3. Number of new summer Chinook redds counted during different weeks in the Methow River, September through mid-November 2016.

## Spawning Escapement

Spawning escapement for Methow summer Chinook was calculated as the total number of redds times the fish per redd ratio estimated from fish sampled at Wells Dam. ${ }^{28}$ The estimated fish per redd ratio for Methow summer Chinook in 2016 was 2.01 . Multiplying this ratio by the number of redds counted in the Methow River resulted in a total spawning escapement of 2,241 summer Chinook (Table 9.17).
Table 9.17. Spawning escapements for summer Chinook in the Methow River for return years 19892016.

* Spawning escapement was calculated using the "Modified Meekin Method" (i.e., $3.1 \times$ jack multiplier).

### 9.6 Carcass Surveys

Surveys for Methow summer Chinook carcasses were conducted during late September to midNovember 2016 in the Methow River (see Appendix O for more details).

## Number sampled

A total of 587 summer Chinook carcasses were sampled during September through mid-November in the Methow River (Table 9.18). This was greater than the overall average of 523 carcasses sampled since 1991.
Table 9.18. Numbers of summer Chinook carcasses sampled within each survey reach on the Methow River, 1991-2016. Reach codes are described in Table 2.11.

${ }^{a}$ An additional 113 carcasses were sampled, but reach was not identified.

## Carcass Distribution and Origin

Summer Chinook carcasses were not evenly distributed among reaches within the Methow River in 2016 (Table 9.18; Figure 9.4). Most of the carcasses were found in the lower three reaches (downstream from Twisp). Few carcasses were observed upstream from Winthrop (Reaches 6 and 7).

## Methow Summer Chinook Carcasses

Figure 9.4. Percent of summer Chinook carcasses sampled within different reaches on the Methow River during September through mid-November 2016. Reach codes are described in Table 2.11.

Based on the available data (1991-2015), hatchery and wild summer Chinook carcasses were not distributed equally among the reaches in the Methow River (Table 9.19). A larger percentage of hatchery carcasses occurred in the lower reaches, while a larger percentage of wild summer Chinook carcasses occurred in upstream reaches (Figure 9.5).

## Methow Summer Chinook

Figure 9.5. Distribution of wild and hatchery produced carcasses in different reaches on the Methow River, 1993-2016. Reach codes are described in Table 2.11.

## Sampling Rate

Overall, $26 \%$ of the total spawning escapement of summer Chinook in the Methow River basin was sampled in 2016 (Table 9.20). Sampling rates among survey reaches varied from 23 to $50 \%$.

Table 9.20. Number of redds and carcasses, total spawning escapement, and sampling rates for summer Chinook in the Methow River basin, 2016. Reach codes are described in Table 2.11.

| Survey reach | Total number of <br> redds | Total number of <br> carcasses | Total spawning <br> escapement | Sampling rate |
| :---: | :---: | :---: | :---: | :---: |
| Methow 1 (M1) | 182 | 83 | 366 | 0.23 |
| Methow 2 (M2) | 309 | 168 | 621 | 0.27 |

| Methow 6 (M6) | 1 | 1 | 2 | 0.50 |

| Survey reach | Total number of <br> redds | Total number of <br> carcasses | Total spawning <br> escapement | Sampling rate |
| :---: | :---: | :---: | :---: | :---: |
| Methow 7 (M7) | 9 | 5 | 18 | 0.28 |
| Total | $\mathbf{1 , 1 1 5}$ | $\mathbf{5 8 7}$ | $\mathbf{2 , 2 4 1}$ | 0.26 |

## Length Data

Mean lengths ( $\mathrm{POH}, \mathrm{cm}$ ) of male and female summer Chinook carcasses sampled during surveys on the Methow River in 2016 are provided in Table 9.21. The average size of males and females sampled in the Methow River were 66 cm and 68 cm , respectively.
Table 9.21. Mean lengths (postorbital-to-hypural length; cm ) and standard deviations (in parentheses) of male and female summer Chinook carcasses sampled in different reaches on the Methow River, 2016. Reach codes are described in Table 2.11.

| Stream/watershed | Mean length (cm) |  |
| :---: | :---: | :---: |
|  | Male | Female |
| Methow 1 (M1) | $65.3(6.0)$ | $67.9(5.2)$ |
| Methow 2 (M2) | $64.4(8.7)$ | $67.9(5.4)$ |
| Methow 3 (M3) | $67.2(7.6)$ | $68.5(4.1)$ |
| Methow 4 (M4) | $65.2(9.1)$ | $66.8(4.6)$ |
| Methow 5 (M5) | $68.3(5.6)$ | $69.2(4.9)$ |
| Methow 6 (M6) | -- | $67.0(-)$ |
| Methow 7 (M7) | $67.3(2.1)$ | $64.0(2.8)$ |
| Total | $\mathbf{6 5 . 5}(8.0)$ | $\mathbf{6 8 . 3}(\mathbf{4 . 7})$ |

### 9.7 Life History Monitoring

Life history characteristics of Methow summer Chinook were assessed by examining carcasses on spawning grounds and fish collected or examined at broodstock collection sites, and by reviewing tagging data and fisheries statistics.

## Migration Timing

Migration timing of hatchery and wild Methow/Okanogan summer Chinook was determined from broodstock data collected at Wells Dam. Counting of summer/fall Chinook at Wells Dam occurs from 29 June to 15 November. Broodstock collection at the Dam occurs from early July (week 27) to mid-September (week 37) (Table 2.1). Based on broodstock sampling in 2016, hatchery summer Chinook arrived at Wells Dam earlier than wild summer Chinook (Table 9.22). This was true throughout most of the migration period. In contrast, there was little difference in migration timing between wild and hatchery summer Chinook when data were pooled for the 2007-2016 survey period.

Table 9.22. The week that $10 \%, 50 \%$ (median), and $90 \%$ of the wild and hatchery summer Chinook salmon passed Wells Dam, 2007-2016. The average week is also provided. Migration timing is based on collection of summer Chinook broodstock at Wells Dam.

| Survey year | Origin | Methow/Okanogan Summer Chinook Migration Time (week) |  |  |  | Sample size |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| 2016 | Wild | 26 | 29 | 39 | 30 | 314 |
|  | Hatchery | 25 | 28 | 34 | 29 | 251 |
| Average | Wild | 27 | 30 | 35 | 30 | 377 |
|  | Hatchery | 27 | 30 | 34 | 30 | 555 |
| Median | Wild | 27 | 30 | 34 | 30 | 347 |
|  | Hatchery | 27 | 30 | 34 | 30 | 512 |

## Age at Maturity

Because hatchery summer Chinook are released after one year of rearing and natural-origin summer Chinook migrate primarily as age-0 fish, total ages will differ between hatchery and natural-origin Chinook (see Hillman et al. 2011). Therefore, in this section, we evaluated age at maturity by comparing differences in salt (ocean) ages between the two groups.

Most of the wild and hatchery summer Chinook sampled during the period 1993-2016 in the Methow River were salt age-3 fish (Table 9.23; Figure 9.6). A higher percentage of salt age-4 wild Chinook returned to the basin than did salt age- 4 hatchery Chinook. In contrast, a higher proportion of salt age- 1 and 2 hatchery fish returned than did salt age- 1 and 2 wild fish. Thus, a higher percentage of wild fish returned at an older age than did hatchery fish.

Table 9.23. Proportions of wild and hatchery summer Chinook of different salt (ocean) ages sampled on spawning grounds in the Methow River, 1993-2015.

| Sample year | Origin | Salt age |  |  |  |  |  | Sample size |

## Methow Summer Chinook

Figure 9.6. Proportions of wild and hatchery summer Chinook of different salt (ocean) ages sampled at broodstock collection sites and on spawning grounds in the Methow River for the combined years 19932016.

## Size at Maturity

On average, hatchery summer Chinook were about 5 cm smaller than wild summer Chinook sampled in the Methow River basin (Table 9.24). This is likely because a higher percentage of wild fish returned as salt age- 4 fish than did hatchery fish. Future analyses will compare sizes of hatchery and wild fish of the same age groups and sex.
Table 9.24. Mean lengths ( $\mathrm{POH} ; \mathrm{cm}$ ) and variability statistics for wild and hatchery summer Chinook sampled in the Methow River basin, 1993-2015; SD = 1 standard deviation.

${ }^{a}$ These years include sizes reported in annual reports. The data contained in the WDFW database do not include all these data.

## Contribution to Fisheries

Most of the harvest on hatchery-origin Methow summer Chinook occurred in the Ocean (Table 9.25). Ocean harvest has made up $13 \%$ to $99 \%$ of all hatchery-origin Methow summer Chinook harvested. Brood years 1989, 1998, 2006, 2008, and 2010 provided the largest harvests, while brood years 1996 and 1999 provided the lowest.
Table 9.25. Estimated number and percent (in parentheses) of hatchery-origin Methow summer Chinook captured in different fisheries, brood years 1989-2010.

## Straying

Stray rates were determined by examining CWTs recovered on spawning grounds within and outside the Methow River basin. Targets for strays based on return year (recovery year) within the upper Columbia River basin (Priest Rapids Dam to Chief Joseph Dam) should be less than 10\% and targets for strays outside the upper Columbia River should be less than 5\%. The target for brood year stay rates should be less than $5 \%$.
Few hatchery-origin Methow summer Chinook have strayed into basins outside the Methow (Table 9.26). Although hatchery-origin Methow summer Chinook have strayed into the Wenatchee River basin, Okanogan River basin, Entiat River basin, Chelan tailrace, and Hanford Reach, on average, they have made up less than $1 \%$ of the spawning escapement within those areas.
Table 9.26. Number and percent of spawning escapements within other non-target basins that consisted of hatchery-origin Methow summer Chinook, return years 1994-2015. For example, for return year 2002, $0.4 \%$ of the summer Chinook escapement in the Okanogan River basin consisted of hatchery-origin Methow summer Chinook. Percent strays should be less than $10 \%$.

| 2015 | 0 | 0.0 | 40 | 0.3 | 4 | 0.3 | 0 | 0.0 | 0 | 0.0 |
| Average | 0 | 0.0 | 19 | 0.3 | 3 | 0.3 | 0 | 0.1 | 1 | 0.0 |
| Median | 0 | 0.0 | 12 | 0.2 | 0 | 0.0 | 0 | 0.0 | 0 | 0.0 |

Based on brood year analyses, on average, about $3.9 \%$ of the returns have strayed into non-target populations, falling within the acceptable level of less than 5\% (Table 9.27). Depending on brood year, percent strays into non-target spawning areas have ranged from $0-17.1 \%$. Few ( $<1 \%$ on average) have strayed into non-target hatchery programs.
Table 9.27. Number and percent of hatchery-origin Methow summer Chinook that homed to target spawning areas and the target hatchery program, and number and percent that strayed to non-target spawning areas and non-target hatchery programs, by brood years 1989-2010. Percent stays should be less than 5\%.

* Homing to the target hatchery includes Methow hatchery summer Chinook that are captured and included as broodstock in the Methow Hatchery program. These hatchery fish are typically collected at Wells Dam.

## Genetics

Genetic studies were conducted to investigate relationships among temporally replicated collections of summer Chinook from the Wenatchee River, Methow River, and Okanogan River in the upper Columbia River basin (Kassler et al. 2011; the entire report is appended as Appendix N ). A total of 2,416 summer Chinook were collected from tributaries in the upper Columbia River basin. Two collections of natural-origin summer Chinook from 1993 (prior to the supplementation program) were taken from the Wenatchee River basin ( $\mathrm{N}=139$ ) and compared to collections of hatchery and natural-origin Chinook from 2006 and 2008 ( $\mathrm{N}=380$ ). Two pre-supplementation collections from the Methow River (1991 and 1993) were compared to supplementation collections from 2006 and $2008(\mathrm{~N}=362)$. Three pre-supplementation collections from the Okanogan River Basin (1991, 1992, and 1993) were compared with supplementation collections from 2006 and $2008(\mathrm{~N}=669)$. A collection of natural-origin summer Chinook from the Chelan River was also analyzed ( $\mathrm{N}=70$ ). Additionally, hatchery collections from Eastbank Hatchery (Wenatchee and Methow/Okanogan stock; $\mathrm{N}=221$ ) and Wells Hatchery $(\mathrm{N}=294)$ were analyzed and compared to the in-river collections. Summer Chinook data (provided by the USFWS) from the Entiat River $(\mathrm{N}=190)$ were used for comparison. Lastly, data from eight collections of fall Chinook ( $\mathrm{N}=2,408$ ) were compared to the collections of summer Chinook. Samples of natural and hatchery-origin summer Chinook were analyzed and compared to determine if the supplementation programs have affected the genetic structure of these populations. The study also
calculated the effective number of breeders for collection locations of natural and hatchery-origin summer Chinook from 1993 and 2008.

In general, population differentiation was not observed among the temporally replicated collection locations. A single collection from the Okanogan River (1993) was the only collection showing statistically significant differences. The effective number of breeders was not statistically different from the early collection in 1993 in comparison to the late collection in 2008. Overall, these analyses revealed a lack of differentiation among the temporal replicates from the same locations and among the collection from different locations, suggesting the populations have been homogenized or that there has been substantial gene flow among populations. Additional comparisons among summer-run and fall-run Chinook populations in the upper Columbia River were conducted to determine if there was any differentiation between Chinook with different run timing. These analyses revealed pairwise $\mathrm{F}_{\text {ST }}$ values that were less than 0.01 for the collections of summer Chinook to collections of fall Chinook from Hanford Reach, lower Yakima River, Priest Rapids, and Umatilla. Collections of fall Chinook from Crab Creek, Lyons Ferry Hatchery, Marion Drain, and Snake River had pairwise $\mathrm{F}_{\text {ST }}$ values that were higher in comparison to the collections of summer Chinook. The consensus clustering analysis did not provide good statistical support to the groupings, but did show relationships among collections based on geographic proximity. Overall the summer and fall run Chinook that have historically been spawned together were not differentiated while fall Chinook from greater geographic distances were differentiated.

## Proportionate Natural Influence

Another method for assessing the genetic risk of a supplementation program is to determine the influence of the hatchery and natural environments on the adaptation of the composite population. This is estimated by the proportion of natural-origin fish in the hatchery broodstock ( pNOB ) and the proportion of hatchery-origin fish in the natural spawning escapement ( pHOS ). We calculated Proportionate Natural Influence (PNI) by iterating Ford's (2002) equations 5 and 6 to equilibrium, using a heritability of 0.3 and a selection strength of three standard deviations. The larger the PNI value, the greater the strength of selection in the natural environment relative to that of the hatchery environment. For the natural environment to dominate selection, PNI should be greater than 0.50 , and important integrated populations should have a PNI of at least 0.67 (HSRG/WDFW/NWIFC 2004).

For brood years 1993-2003, the PNI values were generally less than 0.67 (Table 9.28). However, since brood year 2003, PNI has generally been greater than 0.67 ; brood year 2015 had a PNI value of 0.83 .

Table 9.28. Proportionate Natural Influence (PNI) values for the Methow summer Chinook supplementation program for brood years 1989-2015. NOS = number of natural-origin Chinook on the spawning grounds; HOS = number of hatchery-origin Chinook on the spawning grounds; NOB = number of natural-origin Chinook collected for broodstock; and HOB = number of hatchery-origin Chinook included in hatchery broodstock.

| Brood year | Spawners |  |  | Broodstock $_{*}^{*}$ PNI $^{\mathbf{a}}$ |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| 2015 | 3,138 | 814 | 0.21 | 103 | 0 | 1.00 | 0.83 |
| Average | 1,180 | 721 | 0.33 | 380 | 157 | 0.73 | 0.69 |
| Median | 1,122 | 618 | 0.39 | 341 | 155 | 0.80 | 0.68 |

${ }^{\text {a }}$ PNI was calculated previously using PNI approximate equation 11 (HSRG 2009; their Appendix A). All PNI values presented here were recalculated by iterating Ford's (2002) equations 5 and 6 to equilibrium using a heritability of 0.3 and a selection strength of three standard deviations. C. Busack, NOAA Fisheries, 21 March 2016, provided the model for calculating PNI.

## Post-Release Survival and Travel Time

We used PIT-tagged fish to estimate survival rates and travel time (arithmetic mean days) of hatchery summer Chinook from the Methow River release site to McNary Dam, and smolt to adult ratios (SARs) from release to detection at Bonneville Dam (Table 9.29). ${ }^{29}$ Over the five brood years for which PIT-tagged hatchery fish were released, survival rates from the Methow River to McNary Dam ranged from 0.485 to 0.747 ; SARs from release to detection at Bonneville Dam ranged from 0.000 to 0.016 . Average travel time from the Methow River to McNary Dam ranged from 17 to 55 days.

[^26]Table 9.29. Total number of Methow hatchery summer Chinook released with PIT tags, their survival and travel times (mean days) to McNary Dam, and smolt-to-adult (SAR) ratios for brood years 2008-2014. Standard errors are shown in parentheses. NA = not available (i.e., not all the fish from the release groups have returned to the Columbia River).

| Brood year | Number of tagged <br> fish released | Survival to McNary <br> Dam | Travel time to <br> McNary Dam (d) | SAR to Bonneville <br> Dam |
| :---: | :---: | :---: | :---: | :---: |
| 2008 | 10,094 | $0.747(0.055)$ | $39.1(13.0)$ | $0.016(0.001)$ |

| 2010 | 0 | - | -- | -- |
| 2011 | 0 | -- | -- | -- |
| 2012 | 9,801 | $0.545(0.046)$ | $17.0(8.1)$ | $0.000(0.000)$ |
| 2013 | 9,825 | $0.560(0.101)$ | $54.5(8.3)$ | NA |
| 2014 | 4,992 | $0.624(0.053)$ | $24.5(8.1)$ | NA |

## Natural and Hatchery Replacement Rates

Natural replacement rates (NRR) were calculated as the ratio of natural-origin recruits (NOR) to the parent spawning population (spawning escapement). Natural-origin recruits are naturally produced (wild) fish that survive to contribute to harvest (directly or indirectly), to broodstock, and to spawning grounds. We do not account for fish that died in route to the spawning grounds (migration mortality) or died just before spawning (pre-spawn mortality) (see Appendix B in Hillman et al. 2012). We calculated NORs with and without harvest. NORs without harvest include all returning fish that either returned to the basin or were collected as wild broodstock. NORs with harvest include all fish harvested and are based on a brood year harvest rates from the hatchery program. For brood years 1989-2009, NRR for summer Chinook in the Methow averaged 1.11 (range, 0.10-4.90) if harvested fish were not included in the estimate and 2.13 (range, 0.18-10.84) if harvested fish were included in the estimate (Table 9.30). NRRs for more recent brood years will be calculated as soon as all tag recoveries and sampling rates have been loaded into the database.

Hatchery replacement rates (HRR) are the hatchery adult-to-adult returns and were calculated as the ratio of hatchery-origin recruits (HOR) to the parent broodstock collected. These rates should be greater than the NRRs and greater than or equal to 3.0 (the calculated target value in Hillman et al. 2013). The target value of 3.0 includes harvest. HRRs exceeded NRRs in 13 out of the 21 years of data, regardless if harvest was or was not included in the estimate (Table 9.30). Hatchery replacement rates for Methow summer Chinook have exceeded the estimated target value of 3.0 in ten of the 20 years of data.

Table 9.30. Broodstock collected, spawning escapements, natural and hatchery-origin recruits (NOR and HOR), and natural and hatchery replacement rates (NRR and HRR; with and without harvest) for wild summer Chinook in the Methow River basin, brood years 1989-2009.

| Brood year | Broodstock Collected | Spawning Escapement | Harvest not included |  |  |  | Harvest included |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | HOR | NOR | HRR | NRR | HOR | NOR | HRR | NRR |

## Smolt-to-Adult Survivals

Smolt-to-adult survival ratios (SARs) were calculated as the number of hatchery adult recaptures divided by the number of tagged hatchery smolts released. Here, SARs were based on CWT returns. For the available brood years, SARs have ranged from 0.00008 to 0.01883 for hatchery summer Chinook in the Methow River basin (Table 9.31).
Table 9.31. Smolt-to-adult ratios (SARs) for Methow summer Chinook, brood years 1989-2010.

| Brood year | Number of tagged smolts <br> released $^{\mathbf{a}}$ | Estimated adult <br> captures $^{\mathbf{b}}$ | SAR |
| :---: | :---: | :---: | :---: |
| 1989 | 358,237 | 2,871 | 0.008010 |
| 1990 | 371,483 | 361 | 0.000970 |
| 1991 | 377,097 | 130 | 0.000340 |

| Brood year | Number of tagged smolts released ${ }^{\text {a }}$ | Estimated adult captures ${ }^{\text {b }}$ | SAR |
| :---: | :---: | :---: | :---: |
| 1992 | 392,636 | 138 | 0.000350 |
| 1993 | 200,345 | 62 | 0.000310 |
| 1994 | 400,488 | 710 | 0.001770 |
| 1995 | 344,974 | 229 | 0.000660 |
| 1996 | 289,880 | 73 | 0.000250 |
| 1997 | 380,430 | 647 | 0.001700 |
| 1998 | 202,559 | 3,812 | 0.018820 |
| 1999 | 422,473 | 33 | 0.000080 |
| 2000 | 334,337 | 770 | 0.002300 |
| 2001 | 246,159 | 930 | 0.003780 |
| 2002 | 310,846 | 895 | 0.002880 |
| 2003 | 353,495 | 232 | 0.000660 |
| 2004 | 394,490 | 496 | 0.001260 |
| 2005 | 262,496 | 961 | 0.003660 |
| 2006 | 417,795 | 3,786 | 0.009060 |
| 2007 | 426,188 | 479 | 0.001120 |
| 2008 | 373,234 | 4,088 | 0.010950 |
| 2009 | 450,237 | 952 | 0.002110 |
| 2010 | 428,458 | 1,289 | 0.003008 |
| Average | 351,743 | 1,088 | 0.00337 |
| Median | 372,359 | 679 | 0.00174 |

${ }^{\text {a }}$ Includes all tag codes and CWT released fish (CWT + Ad Clip fish and CWT-only fish).
${ }^{\mathrm{b}}$ Includes estimated recoveries (spawning ground, hatcheries, harvest, etc.) and observed recoveries if estimated recoveries were unavailable.

### 9.8 ESA/HCP Compliance

## Broodstock Collection

Summer Chinook adults collected at Wells Dam are used primarily for the Methow supplementation programs. On an as needed basis, adults collected at Wells Dam may be used to augment adult collections for the Okanogan summer Chinook supplementation program. Per the 2014 broodstock collection protocol, 100 natural-origin (adipose fin present) adults were targeted for collection between 1 July and 15 September at the West Ladder of Wells Dam for the Methow summer Chinook program. Actual collections occurred between 1 July and 3 September and totaled 100 summer Chinook. ESA Permit 1347 provides authorization to collect Methow and Okanogan summer Chinook at Wells Dam three days per week and up to 16 hours per day from July through November. During 2014, broodstock collection activities were accomplished within the allowable trapping days authorized under ESA Permit 1347.

Collection of Methow summer Chinook broodstock at Wells Dam occurred concurrently with collection of summer steelhead for the Wells steelhead program authorized under ESA Section 10 Permit 1395. Encounters with steelhead and spring Chinook during Methow summer Chinook broodstock collections did not result in takes that were outside those authorized in Permit 1347 and in Permit 1395 for the Wells Steelhead program. Steelhead encountered during summer Chinook collections that were not required for steelhead broodstock were passed at the trap site and were not physically handled. Any spring Chinook encountered during summer Chinook broodstock activities were also passed without handling. No chinook were collected at Wells Dam for the 2014 Okanogan summer Chinook program.

## Hatchery Rearing and Release

The 2014 brood Methow summer Chinook reared throughout their juvenile life-stages at Eastbank Fish Hatchery and the Carlton Acclimation Pond without incident (see Section 9.2). The 2014 brood smolt release totaled 167,616 summer Chinook, representing $83.8 \%$ of the $200,000-$ production objective and was compliant with the $10 \%$ overage allowable in ESA Section 10 Permit 1347. Lower than anticipated fecundity ( $94 \%$ of the biological assumption used in the 2014 broodstock collection protocols) was the largest factor in not meeting the full program, followed by lower than expected overwinter survival ( $87.1 \%$ ).

## Hatchery Effluent Monitoring

Per ESA Permits 1196, 1347, 1395, 18118, 18120, and 18121, permit holders shall monitor and report hatchery effluents in compliance with applicable National Pollution Discharge Elimination Systems (NPDES) (EPA 1999) permit limitations. There were no NPDES violations reported at PUD Hatchery facilities during the period 1 January through 31 December 2016. NPDES monitoring and reporting for PUD Hatchery Programs during 2016 are provided in Appendix F.

## Spawning Surveys

Summer Chinook spawning ground surveys conducted in the Methow River basin during 2016 were consistent with ESA Section 10 Permit No. 1347. Because of the difficulty of quantifying the level of take associated with spawning ground surveys, the Permit does not specify a take level associated with these activities, even though it does authorize implementation of spawning ground surveys. Therefore, no take levels are reported. However, to minimize potential effects to established redds, wading was restricted to the extent practical, and extreme caution was used to avoid established redds when wading was required.

# SECTION 10: OKANOGAN/SIMILKAMEEN SUMMER CHINOOK 

The goal of summer Chinook salmon supplementation in the Okanogan Basin is to use artificial production to replace adult production lost because of mortality at Wells, Rocky Reach, and Rock Island dams, while not reducing the natural production or long-term fitness of summer Chinook in the basin. The Rock Island Fish Hatchery Complex began operation in 1989 under funding from Chelan PUD. The Complex operated originally through the Rock Island Settlement Agreement, but since 2004 has operated under the Anadromous Fish Agreement and Habitat Conservation Plans.

Before 2012, adult summer Chinook were collected for broodstock from the run-at-large at the east ladder trapping facility at Wells Dam. Since then, the Colville Tribes collect broodstock using purse seines in the Okanogan and Columbia rivers. The goal was to collect up to 334 adult summer Chinook for the Okanogan program. Broodstock collection occurred from about 7 July through 15 September with trapping occurring no more than 16 hours per day, three days a week. If naturalorigin broodstock collection fell short of expectation, hatchery-origin adults could be collected to make up the difference.

Before 2012, adult summer Chinook were spawned and reared at Eastbank Fish Hatchery. Juvenile summer Chinook were transferred from the hatchery to Similkameen Acclimation Pond in October. In addition, since 2005, about $20 \%(100,000)$ of the juveniles were transferred to Bonaparte Pond. Chinook were released from the ponds in April to early May.

Prior to 2012, the production goal for the Okanogan summer Chinook supplementation program was to release 576,000 yearling smolts into the Similkameen and Okanogan rivers at ten fish per pound. Beginning with the 2012 brood, the revised production goal is to release 166,569 yearling smolts into the rivers. Targets for fork length and weight are $176 \mathrm{~mm}(\mathrm{CV}=9.0)$ and 45.4 g , respectively. Over $90 \%$ of these fish are marked with CWTs. In addition, since 2009 , juvenile summer Chinook have been PIT tagged annually.
The Colville Tribes began monitoring the Okanogan/Similkameen summer Chinook program in 2013. Their monitoring results are published in annual reports to Bonneville Power Administration (BPA). The purpose of retaining this section is to provide readers with monitoring data collected with Chelan PUD funding through brood year 2012. Thus, this section tracks the status and life histories of summer Chinook up to and including brood year 2012. Results from monitoring brood year 2013 and beyond will be included in annual reports to BPA.

### 10.1 Broodstock Sampling

Summer Chinook broodstock for the Okanogan/Similkameen and Methow programs was typically collected at the East and West Ladders of Wells Dam. In 2012, broodstock was also collected at the mouth of the Okanogan River via purse seine. In 2012, a total of 81 summer Chinook ( 79 wild Chinook and two hatchery Chinook) ${ }^{30}$ were spawned for the Okanogan program. Refer to Section

[^27]9.1 for information on the origin, age and length, sex ratios, and fecundity of summer Chinook broodstock collected at Wells Dam before 2013.

### 10.2 Hatchery Rearing

In this section, we describe the hatchery rearing of the Okanogan summer Chinook program through brood year 2012. The Colville Tribes began operating the program in 2013. Information on rearing history since brood year 2012 can be found in annual reports prepared by the Colville Tribes and submitted to BPA.

## Rearing History

## Number of eggs taken

Based on the unfertilized egg-to-release survival standard of $81 \%$, a total of 711,111 eggs were required to meet the program release goal of 576,000 smolts through the 2011 brood year. An evaluation of the program in 2012 determined that 205,134 eggs were needed to meet the revised release goal of 166,569 smolts. This revised goal began with brood year 2012. From 1989 through 2012, the egg take goal was reached in 13 of those years (Table 10.1).
Table 10.1. Numbers of eggs taken from summer Chinook broodstock for the Okanogan program during 1989-2012. From 1989-2011, broodstock were collected at Wells Dam. In 2012, broodstock were collected in purse seines in the Okanogan River.

## Release Information

## Numbers released

The 2012 Okanogan summer Chinook program achieved $68.4 \%$ of the 166,569 target goal with about 114,000 fish being released volitionally into the Similkameen River (Table 10.3).
Table 10.3. Numbers of Okanogan summer Chinook smolts released from the Similkameen and Bonaparte ponds, brood years 1989-2012; NA = not available. For brood years 1998-2012, the release target was 576,000 smolts. Since brood year 2013, the release target for Okanogan summer Chinook is 114,000 smolts.

## Numbers tagged

The 2012 brood Okanogan summer Chinook from the Similkameen facility were 99.4\% CWT and adipose fin-clipped (Table 10.3). Table 10.4 summarizes the number of hatchery summer Chinook that have been PIT-tagged and released into the Okanogan River basin. No fish from the 2012 brood year were PIT tagged.
Table 10.4. Summary of PIT-tagging activities for Okanogan hatchery summer Chinook, brood years 20082011.

| Brood year | Release year | Number of fish <br> tagged | Number of <br> tagged fish that <br> died | Number of tags <br> shed | Number of <br> tagged fish <br> released |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 2008 | 2010 | 5,700 (high density) | 1,169 | 0 | 4,531 |
|  | 5,700 (low density) | 1,407 | 0 | 4,293 |  |

| 2010 | 2012 | 0 | 0 | 0 | 0 |

| Brood year | Release year | Number of fish <br> tagged | Number of <br> tagged fish that <br> died | Number of tags <br> shed | Number of <br> tagged fish <br> released |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 2011 | 2013 | 5,100 | 64 | 0 | 5,036 |

## Fish size and condition at release

Size at release of the Similkameen population was $73.3 \%$ and $56.8 \%$ of the fork length and weight targets, respectively. The CV for fork length exceeded the target by $18.9 \%$ (Table 10.5). There was no Bonaparte program for the 2014 release year.
Table 10.5. Mean lengths (FL, mm), weight ( g and fish/pound), and coefficient of variation (CV) of Okanogan summer Chinook smolts released from the hatchery, brood years 1989-2012. Size targets are provided in the last row of the table.

| Brood year | Release year | Fork length (mm) |  | Mean weight |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Mean | CV | Grams (g) | Fish/pound |

| Targets |  | 176 | 9.0 | 45.4 | 10 |

## Survival Estimates

Overall survival of Okanogan summer Chinook from green (unfertilized) egg to release was above the standard set for the program (Table 10.6). Low survival can be attributed to high mortality after ponding through release because of external fungus. Currently, it is unknown if gamete viability is sex biased or is uniform between sexes and more influenced by between-year environmental variations.

Table 10.6. Hatchery life-stage survival rates (\%) for Okanogan summer Chinook, brood years 1989-2012. Survival standards or targets are provided in the last row of the table.

| Brood year | Rearing facility | Collection to spawning |  | Unfertilized egg-eyed | $\begin{gathered} \text { Eyed } \\ \text { egg- } \\ \text { ponding } \end{gathered}$ | 30 d after ponding |  | Ponding to release | Transport to release | Unfertilized egg-release |

${ }^{\text {a }}$ Survival rates were calculated from the aggregate population collected at Wells Fish Hatchery volunteer channel and left- and right-ladder traps at Wells Dam.
${ }^{\mathrm{b}}$ Survival rates were calculated from aggregate collections at Wells east fish ladder for the Methow and Okanogan/Similkameen programs. About $59 \%$ of the total fish collected were used to estimate survival rates.

### 10.3 Disease Monitoring

Results of adult broodstock bacterial kidney disease (BKD) monitoring for Methow/Okanogan summer Chinook are shown in Table 9.12 in Section 9.3.

### 10.4 Spawning Surveys

Surveys for Okanogan/Similkameen summer Chinook redds were conducted from late September to mid-November in the Okanogan and Similkameen rivers. Total redd counts (not peak counts) were conducted in the rivers.

## Redd Counts

During the survey period 1989 through 2016, the number of summer Chinook redds in the Okanogan River basin averaged 2,179 and ranged from 110 to 6,025 (Table 10.7).
Table 10.7. Total number of redds counted in the Okanogan River basin, 1989-2016. The Colville Tribes provided data for survey years 2013 to present.

## Spawning Escapement

Spawning escapement for Okanogan/Similkameen summer Chinook was calculated as the total number of redds times the fish per redd ratio estimated from fish sampled at Wells Dam. ${ }^{31}$ During the survey period 1989 through 2016, the summer Chinook spawning escapement within the Okanogan River basin averaged 5,870 and ranged from 473 to 13,857 (Table 10.8).

Table 10.8. Spawning escapements for summer Chinook in the Okanogan and Similkameen rivers for return years 1989-2016. The Colville Tribes provided data for return years 2013 to present.

* Spawning escapement was calculated using the "Modified Meekin Method" (i.e., $3.1 \times$ jack multiplier).

### 10.5 Carcass Surveys

Surveys for summer Chinook carcasses were conducted during late September to mid-November in the Okanogan and Similkameen rivers.

## Number sampled

During the survey period 1993 through 2016, the number of summer Chinook carcasses sampled in the Okanogan River basin averaged 1,727 and ranged from 115 to 5,276 (Table 10.9). In all years, most were sampled in the upper Okanogan River and lower Similkameen River (Table 10.9).

Table 10.9. Numbers of summer Chinook carcasses sampled within each survey reach in the Okanogan River basin, 1993-2016. Reach codes are described in Table 2.11. The Colville Tribes provided data for survey years 2013 to present.

| Median | 0 | 3 | 31 | 15 | 175 | 322 | 715 | 106 | 1,525 |

${ }^{\text {a }} 25$ additional carcasses were sampled on the Similkameen and 46 on the Okanogan without any reach designation.
${ }^{\mathrm{b}}$ One additional carcasses was sampled on the Similkameen without any reach designation.
c 793 carcasses were sampled on the Similkameen before initiation of spawning (pre-spawn mortality) and an additional 40 carcasses were sampled on the Okanogan. The cause of the high mortality (Ichthyophthirius multifilis and Flavobacterium columnarae) was exacerbated by high river temperatures.

## Carcass Distribution and Origin

Based on the available data (1991-2015), most fish, regardless of origin, were found in Reach 1 on the Similkameen River (Driscoll Channel to Oroville Bridge) (Table 10.10). However, a slightly larger percentage of hatchery fish were found in reaches on the Similkameen River than were wild fish (Figure 10.1). In contrast, a larger percentage of wild fish were found in reaches on the Okanogan River.

Table 10.10. Numbers of wild and hatchery summer Chinook carcasses sampled within different reaches in the Okanogan River basin, 1993-2015.

| Survey year | Origin | Survey reach |  |  |  |  |  |  |  | Total |

## Okan/Similk Summer Chinook

Figure 10.1. Distribution of wild and hatchery produced carcasses in different reaches in the Okanogan River basin, 1993-2015. Reach codes are described in Table 2.11.

### 10.6 Life History Monitoring

Life history characteristics of Okanogan/Similkameen summer Chinook were assessed by examining carcasses on spawning grounds and fish collected or examined at broodstock collection sites, and by reviewing tagging data and fisheries statistics.

## Migration Timing

Migration timing for Okanogan/Similkameen summer Chinook is described in Section 9.6.

## Age at Maturity

Because hatchery summer Chinook are released after one year of rearing and natural-origin summer Chinook migrate primarily as age-0 fish, total ages will differ between hatchery and natural-origin Chinook (see Hillman et al. 2011). Therefore, in this section, we evaluated age at maturity by comparing differences in salt (ocean) ages between the two groups.

Most of the wild and hatchery summer Chinook sampled during the period 1993-2015 in the Okanogan River basin were salt age-3 fish (Table 10.11; Figure 10.2). A higher percentage of salt age- 4 wild Chinook returned to the basin than did salt age-4 hatchery Chinook. In contrast, a higher proportion of salt age-1 and 2 hatchery fish returned than did salt age- 1 and 2 wild fish. Thus, a higher percentage of wild fish returned at an older age than did hatchery fish.
Table 10.11. Proportions of wild and hatchery summer Chinook of different salt (ocean) ages sampled on spawning grounds in the Okanogan River basin, 1993-2015.

${ }^{\text {a }}$ There was one salt age-6 hatchery fish that was not included in this table.

## Okan/Similk Summer Chinook

Figure 10.2. Proportions of wild and hatchery summer Chinook of different salt (ocean) ages sampled at broodstock collection sites and on spawning grounds in the Okanogan River basin for the combined years 1993-2015.

## Size at Maturity

For the period 1993 through 2015, on average, hatchery summer Chinook were about 2 cm smaller than wild summer Chinook sampled in the Okanogan River basin (Table 10.12). This is likely because a higher percentage of wild fish returned as salt age-4 fish than did hatchery fish.

Table 10.12. Mean lengths ( $\mathrm{POH} ; \mathrm{cm}$ ) and variability statistics for wild and hatchery summer Chinook sampled in the Okanogan River basin, 1993-2015; SD $=1$ standard deviation.

## Contribution to Fisheries

Most of the harvest on hatchery-origin Okanogan/Similkameen summer Chinook occurred in the Ocean (Table 10.13). Ocean harvest has made up 37-100\% of all hatchery-origin Okanogan/Similkameen summer Chinook harvested. Brood year 2008 provided the largest harvest, while brood years 1993 and 1996 provided the lowest.
Table 10.13. Estimated number and percent (in parentheses) of hatchery-origin Okanogan/Similkameen summer Chinook captured in different fisheries, brood years 1989-2010.

| Brood year | Ocean fisheries | Columbia River Fisheries |  |  | Total |
| :---: | :---: | :---: | :---: | :---: | :---: |

| Average | 1,786 (68) | 647 (17) | 117 (3) | 606 (13) | 3,157 |
| Median | 1,034 (69) | 238 (18) | 41 (2) | 239 (11) | 1,936 |

## Straying

Stray rates were determined by examining CWTs recovered on spawning grounds within and outside the Okanogan River basin. Targets for strays based on return year (recovery year) within the upper Columbia River basin (Priest Rapids Dam to Chief Joseph Dam) should be less than
$10 \%$ and targets for strays outside the upper Columbia River should be less than 5\%. The target for brood year stay rates should be less than $5 \%$.

Few hatchery-origin Okanogan summer Chinook have strayed into basins outside the Okanogan (Table 10.14). Although hatchery-origin Okanogan summer Chinook have strayed into other spawning areas, they usually made up less than $10 \%$ of the spawning escapement within those areas. The Chelan tailrace has received the largest number of Okanogan strays.

Table 10.14. Number and percent of spawning escapements within other non-target basins that consisted of hatchery-origin Okanogan summer Chinook, return years 1994-2015. For example, for return year 2002, $1 \%$ of the summer Chinook spawning escapement in the Entiat Basin consisted of hatchery-origin Okanogan summer Chinook. Percent strays should be less than $10 \%$.

| Return year | Wenatchee |  | Methow |  | Chelan |  | Entiat |  | Hanford Reach |  |

| 2011 | 0 | 0.0 | 0 | 0.0 | 46 | 3.6 | 0 | 0.0 | 0 | 0.0 |
| 2012 | 7 | 0.1 | 5 | 0.2 | 19 | 1.5 | 0 | 0.0 | 0 | 0.0 |
| 2013 | 0 | 0.0 | 0 | 0.0 | 0 | 0.0 | 0 | 0.0 | 0 | 0.0 |
| 2014 | 0 | 0.0 | 4 | 0.2 | 8 | 0.7 | 0 | 0.0 | 0 | 0.0 |
| 2015 | 4 | 0.1 | 5 | 0.1 | 4 | 0.3 | 0 | 0.0 | 0 | 0.0 |
| Average | 2 | 0.0 | 4 | 0.2 | 16 | 2.4 | 3 | 0.8 | 1 | 0.0 |
| Median | 0 | 0.0 | 2 | 0.1 | 9 | 1.4 | 0 | 0.0 | 0 | 0.0 |

On average, about $1 \%$ of the brood year returns have strayed into non-target populations, falling within the acceptable level of less than $5 \%$ (Table 10.15). Depending on brood year, percent strays into non-target spawning areas have ranged from $0-4.4 \%$. Few ( $<1 \%$ on average) have strayed into non-target hatchery programs.

Table 10.15. Number and percent of hatchery-origin Okanogan summer Chinook that homed to target spawning areas and the target hatchery, and number and percent that strayed to non-target spawning areas and non-target hatchery programs, by brood years 1989-2010. Percent stays should be less than 5\%.

* Homing to the target hatchery includes Okanogan/Similkameen hatchery summer Chinook that are captured and included as broodstock in the Okanogan/Similkameen Hatchery program. These hatchery fish were typically collected at Wells Dam.

## Genetics

Genetic studies were conducted to investigate relationships among temporally replicated collections of summer Chinook from the Wenatchee River, Methow River, and Okanogan River in the upper Columbia River basin (Kassler et al. 2011; the entire report is appended as Appendix N ). A total of 2,416 summer Chinook were collected from tributaries in the upper Columbia River basin. Two collections of natural-origin summer Chinook from 1993 (prior to the supplementation program) were taken from the Wenatchee River basin $(\mathrm{N}=139)$ and compared to collections of
hatchery and natural-origin Chinook from 2006 and 2008 ( $\mathrm{N}=380$ ). Two pre-supplementation collections from the Methow River (1991 and 1993) were compared to supplementation collections from 2006 and $2008(\mathrm{~N}=362)$. Three pre-supplementation collections from the Okanogan River Basin (1991, 1992, and 1993) were compared with supplementation collections from 2006 and $2008(\mathrm{~N}=669)$. A collection of natural-origin summer Chinook from the Chelan River was also analyzed ( $\mathrm{N}=70$ ). Additionally, hatchery collections from Eastbank Hatchery (Wenatchee and Methow/Okanogan stock; $\mathrm{N}=221$ ) and Wells Hatchery $(\mathrm{N}=294)$ were analyzed and compared to the in-river collections. Summer Chinook data (provided by the USFWS) from the Entiat River $(\mathrm{N}=190)$ were used for comparison. Lastly, data from eight collections of fall Chinook ( $\mathrm{N}=2,408$ ) were compared to the collections of summer Chinook. Samples of natural and hatchery-origin summer Chinook were analyzed and compared to determine if the supplementation programs have affected the genetic structure of these populations. The study also calculated the effective number of breeders for collection locations of natural and hatchery-origin summer Chinook from 1993 and 2008.

In general, population differentiation was not observed among the temporally replicated collection locations. A single collection from the Okanogan River (1993) was the only collection showing statistically significant differences. The effective number of breeders was not statistically different from the early collection in 1993 in comparison to the late collection in 2008. Overall, these analyses revealed a lack of differentiation among the temporal replicates from the same locations and among the collection from different locations, suggesting the populations have been homogenized or that there has been substantial gene flow among populations. Additional comparisons among summer-run and fall-run Chinook populations in the upper Columbia River were conducted to determine if there was any differentiation between Chinook with different run timing. These analyses revealed pairwise $\mathrm{F}_{\text {ST }}$ values that were less than 0.01 for the collections of summer Chinook to collections of fall Chinook from Hanford Reach, lower Yakima River, Priest Rapids, and Umatilla. Collections of fall Chinook from Crab Creek, Lyons Ferry Hatchery, Marion Drain, and Snake River had pairwise FST values that were higher in comparison to the collections of summer Chinook. The consensus clustering analysis did not provide good statistical support to the groupings, but did show relationships among collections based on geographic proximity. Overall the summer and fall run Chinook that have historically been spawned together were not differentiated while fall Chinook from greater geographic distances were differentiated.

## Proportionate Natural Influence

Another method for assessing the genetic risk of a supplementation program is to determine the influence of the hatchery and natural environments on the adaptation of the composite population. This is estimated by the proportion of natural-origin fish in the hatchery broodstock ( pNOB ) and the proportion of hatchery-origin fish in the natural spawning escapement (pHOS). We calculated Proportionate Natural Influence (PNI) by iterating Ford's (2002) equations 5 and 6 to equilibrium, using a heritability of 0.3 and a selection strength of three standard deviations. The larger the PNI value, the greater the strength of selection in the natural environment relative to that of the hatchery environment. For the natural environment to dominate selection, PNI should be greater than 0.50 , and important integrated populations should have a PNI of at least 0.67 (HSRG/WDFW/NWIFC 2004).

For brood years 1993-2003, the PNI values were less than 0.67 (Table 10.16). However, since brood year 2003, PNI has generally been greater than 0.67 , save 2008 and 2011. PNI results reported here end with brood year 2012. Beginning with brood year 2013, the Colville

Confederated Tribes report PNI values for Okanogan summer Chinook in their annual reports to BPA.

Table 10.16. Proportionate Natural Influence (PNI) values for the Okanogan/Similkameen summer Chinook supplementation program for brood years 1989-2012. NOS = number of natural-origin Chinook on the spawning grounds; HOS = number of hatchery-origin Chinook on the spawning grounds; $\mathrm{NOB}=$ number of natural-origin Chinook collected for broodstock; and HOB = number of hatchery-origin Chinook included in hatchery broodstock.

| Brood year | Spawners |  |  | Broodstock |  |  | PNI ${ }^{\text {a }}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | NOS | HOS | pHOS | NOB | HOB | pNOB |  |
| 1989 | 1,719 | 0 | 0 | 1,297 | 312 | 0.81 | 1.00 |

| 2002 | 4,346 | 9,511 | 0.69 | 247 | 241 | 0.51 | 0.44 |
| 2003 | 1,933 | 1,487 | 0.43 | 381 | 101 | 0.79 | 0.66 |
| 2004 | 5,309 | 1,412 | 0.21 | 506 | 16 | 0.97 | 0.83 |
| 2005 | 6,441 | 2,448 | 0.28 | 391 | 9 | 0.98 | 0.78 |
| 2006 | 5,507 | 3,094 | 0.36 | 500 | 10 | 0.98 | 0.74 |
| 2007 | 2,983 | 1,434 | 0.32 | 456 | 17 | 0.96 | 0.76 |
| 2008 | 2,998 | 3,977 | 0.57 | 359 | 86 | 0.81 | 0.60 |
| 2009 | 4,204 | 3,340 | 0.44 | 503 | 4 | 0.99 | 0.70 |
| 2010 | 3,189 | 2,763 | 0.46 | 484 | 8 | 0.98 | 0.69 |
| 2011 | 4,642 | 5,039 | 0.52 | 467 | 26 | 0.95 | 0.65 |
| 2012 | 4,494 | 3,731 | 0.45 | 79 | 2 | 0.98 | 0.69 |
| Average | 2,569 | 2,418 | 0.42 | 415 | 176 | 0.69 | 0.64 |
| Median | 1,826 | 2,183 | 0.45 | 370 | 209 | 0.77 | 0.66 |

${ }^{\text {a }}$ PNI was calculated previously using PNI approximate equation 11 (HSRG 2009; their Appendix A). All PNI values presented here were recalculated by iterating Ford's (2002) equations 5 and 6 to equilibrium using a heritability of 0.3 and a selection strength of three standard deviations. C. Busack, NOAA Fisheries, 21 March 2016, provided the model for calculating PNI.

## Post-Release Survival and Travel Time

We used PIT-tagged fish to estimate survival rates and travel times (arithmetic mean days) of hatchery summer Chinook from the Similkameen River release site to McNary Dam, and smolt to
adult ratios (SARs) from release to detection at Bonneville Dam (Table 10.17). ${ }^{32}$ Over the three brood years for which PIT-tagged hatchery fish were released, survival rates from the Similkameen River to McNary Dam ranged from 0.432 to 0.720 ; SARs from release to detection at Bonneville Dam ranged from 0.016 to 0.031 . Average travel time from the Similkameen River to McNary Dam ranged from 41 to 44 days. Although there is only one year in which low densities were compared to high densities (brood year 2008), there was little difference in survival rates and travel times between the two groups (Table 10.17).

Table 10.17. Total number of Okanogan hatchery summer Chinook released with PIT tags, their survival and travel times (mean days) to McNary Dam, and smolt-to-adult (SAR) ratios for brood years 2008-2011. Standard errors are shown in parentheses. NA = not available (i.e., not all the fish from the release groups have returned to the Columbia River).

| Brood year | Number of tagged <br> fish released | Survival to McNary <br> Dam | Travel time to <br> McNary Dam (d) | SAR to Bonneville <br> Dam |
| :---: | :---: | :---: | :---: | :---: |
| 2008 | 4,531 (high density) | $0.445(0.061)$ | $44.0(10.2)$ | $0.028(0.002)$ |
|  | 4,293 (low density) | $0.432(0.050)$ | $41.4(9.7)$ | $0.030(0.003)$ |
| 2009 | 5,089 | $0.720(0.102)$ | $41.5(10.1)$ | $0.016(0.002)$ |
| 2010 | 0 | - | -- | -- |
| 2011 | 5,036 | $0.683(0.064)$ | $41.9(12.3)$ | $0.031(0.002)$ |

## Natural and Hatchery Replacement Rates

Natural replacement rates (NRR) were calculated as the ratio of natural-origin recruits (NOR) to the parent spawning population (spawning escapement). Natural-origin recruits are naturally produced (wild) fish that survive to contribute to harvest (directly or indirectly), to broodstock, and to spawning grounds. We do not account for fish that died in route to the spawning grounds (migration mortality) or died just before spawning (pre-spawn mortality) (see Appendix B in Hillman et al. 2012). We calculated NORs with and without harvest. NORs without harvest include all returning fish that either returned to the basin or were collected as wild broodstock. NORs with harvest include all fish harvested and are based on brood year harvest rates from the hatchery program. For brood years 1989-2009, NRR for summer Chinook in the Okanogan averaged 1.01 (range, 0.16-3.82) if harvested fish were not included in the estimate and 2.41 (range, $0.32-10.26$ ) if harvested fish were included in the estimate (Table 10.18). NRRs for more recent brood years will be calculated as soon as all tag recoveries and sampling rates have been loaded into the database.

Hatchery replacement rates (HRR) are the hatchery adult-to-adult returns and were calculated as the ratio of hatchery-origin recruits (HOR) to the parent broodstock collected. These rates should be greater than the NRRs and greater than or equal to 8.6 (the calculated target value in Hillman et al. 2013). The target value of 8.6 includes harvest. HRRs exceeded NRRs in 18 of the 21 years of data, regardless if harvest was or was not included in the estimate (Table 10.18). Hatchery

[^29]replacement rates for Okanogan summer Chinook have exceeded the estimated target value of 8.6 in 10 of the 21 years of data.

Table 10.18. Broodstock collected, spawning escapements, natural and hatchery-origin recruits (NOR and HOR), and natural and hatchery replacement rates (NRR and HRR; with and without harvest) for wild summer Chinook in the Okanogan River basin, brood years 1989-2009.

| Brood year | Broodstock Collected | Spawning Escapement | Harvest not included |  |  |  | Harvest included |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | HOR | NOR | HRR | NRR | HOR | NOR | HRR | NRR |
| 1989 | 304 | 1,719 | 4,493 | 2,146 | 14.78 | 1.25 | 7,459 | 3,577 | 24.54 | 2.08 |

## Smolt-to-Adult Survivals

Smolt-to-adult survival ratios (SARs) were calculated as the number of hatchery adult recaptures divided by the number of tagged hatchery smolts released. Here, SARs were based on CWT returns. For the available brood years, SARs have ranged from 0.00007 to 0.03239 for hatchery summer Chinook in the Okanogan River basin (Table 10.19).

Table 10.19. Smolt-to-adult ratios (SARs) for Okanogan/Similkameen summer Chinook, brood years 1989-2010.

| Brood year | Number of tagged smolts released ${ }^{\text {a }}$ | Estimated adult captures ${ }^{\text {b }}$ | SAR |
| :---: | :---: | :---: | :---: |
| 1989 | 202,125 | 4,293 | 0.02124 |
| 1990 | 367,207 | 972 | 0.00265 |
| 1991 | 360,380 | 975 | 0.00271 |
| 1992 | 537,190 | 2,282 | 0.00425 |
| 1993 | 379,139 | 117 | 0.00031 |
| 1994 | 217,818 | 1,528 | 0.00702 |
| 1995 | 574,197 | 2,851 | 0.00497 |
| 1996 | 487,776 | 32 | 0.00007 |
| 1997 | 572,531 | 18,543 | 0.03239 |
| 1998 | 287,948 | 7,641 | 0.02654 |
| 1999 | 610,868 | 2,776 | 0.00454 |
| 2000 | 528,639 | 6,765 | 0.01280 |
| 2001 | 26,315 | 424 | 0.01611 |
| 2002 | 245,997 | 1,969 | 0.00800 |
| 2003 | 574,908 | 3,484 | 0.00606 |
| 2004 | 676,222 | 12,892 | 0.01906 |
| 2005 | 273,512 | 1,662 | 0.00608 |
| 2006 | 597,276 | 13,622 | 0.02281 |
| 2007 | 610,379 | 4,881 | 0.00800 |
| 2008 | 516,533 | 14,026 | 0.02715 |
| 2009 | 522,295 | 5,497 | 0.01052 |
| 2010 | 610,927 | 7,805 | 0.01278 |
| Average | 444,554 | 5,229 | 0.01164 |
| Median | 519,414 | 3,168 | 0.00800 |

${ }^{\text {a }}$ Includes all tag codes and CWT released fish (CWT + Ad Clip fish and CWT-only fish).
${ }^{\mathrm{b}}$ Includes estimated recoveries (spawning ground, hatcheries, harvest, etc.) and observed recoveries if estimated recoveries were unavailable.

### 10.7 ESA/HCP Compliance

## Broodstock Collection

Because summer Chinook adults collected at Wells Dam are used for both the Methow and Okanogan supplementation programs, please refer to Section 9.7 for information on ESA compliance during broodstock collection. Direct and/or indirect take of ESA-listed species during broodstock collection for the Okanogan summer Chinook outside of Wells Dam is covered by
permits held by the Colville Tribes. For 2014, no summer Chinook were collected at Wells Dam for the Okanogan summer Chinook program.

## Hatchery Rearing and Release

Activities associated with the spawning, rearing, and release of Okanogan summer Chinook that could result in either direct or incidental take of listed species is covered under ESA permits held by the Colville Tribes.

## Hatchery Effluent Monitoring

Per ESA Permits 1196, 1347, 1395, 18118, 18120, and 18121, permit holders shall monitor and report hatchery effluents in compliance with applicable National Pollution Discharge Elimination Systems (NPDES) (EPA 1999) permit limitations. There were no NPDES violations reported at PUD Hatchery facilities during the period 1 January through 31 December 2016. NPDES monitoring and reporting for PUD Hatchery Programs during 2016 are provided in Appendix F. NPDES reporting for Okanogan summer Chinook only covers the Similkameen acclimation facility and only during the time fish are present.

## SECTION 11: CHELAN FALLS SUMMER CHINOOK

Although the Chelan Falls summer Chinook program (formerly the Turtle Rock program) is an augmentation program, the production of 200,000 fish is No Net Impact (NNI) compensation for passage mortalities associated with Rocky Reach Dam. In addition, the conversion of the subyearling program to a 400,000-yearling program is compensation for lost spawning habitat as a result of the construction of Rocky Reach Dam. In 2011, as part of the periodic recalculation of NNI for Rocky Reach Dam, the previous 200,000 NNI program was reduced to 176,000 fish. This reduced the combined Chelan Falls summer Chinook production from 600,000 to 576,000 beginning with the 2012 brood.

Before 2012, broodstock were collected at Wells Dam and consisted of volunteers to the Wells Fish Hatchery. Summer Chinook were spawned at Wells Fish Hatchery and fertilized eggs were then transferred to Eastbank Fish Hatchery for hatching and rearing. In 2012, adults were collected at Wells Fish Hatchery and then transferred to Eastbank Fish Hatchery for spawning, hatching, and rearing. Beginning in 2013, broodstock collection was initiated at the Eastbank Fish Hatchery Outfall. With returns to the Outfall diminishing, a pilot broodstock collection program was initiated in 2016 at the outlet structure of the water conveyance canal for the Chelan Tailrace Pump Station. Because the pilot collection program was successful, future broodstock for the Chelan Falls Program will be collected at the outlet structure of the water conveyance canal.

The original program consisted of both subyearling (normal and accelerated groups) and yearling releases. Subyearlings were transferred to Turtle Rock Fish Hatchery for acclimation in May. These fish were released in June after about 30 days of acclimation on Columbia River water. The goal of this program was to release $1,620,000$ subyearling summer Chinook ( 810,000 normal and 810,000 accelerated subyearlings) into the Columbia River at 40 fish per pound. Targets for fork length and weight were $112 \mathrm{~mm}(\mathrm{CV}=9.0)$ and 11.4 g , respectively. Over $50 \%$ of both subyearling groups were marked with CWTs. In 2010, the subyearling program was converted to a 400,000yearling program.

The goal of the yearling program was to release 200,000 summer Chinook smolts into the Columbia River from Turtle Rock Fish Hatchery at 10 fish per pound. Targets for fork length and weight were $176 \mathrm{~mm}(\mathrm{CV}=9.0)$ and 45.4 g , respectively. Beginning with the 2006 brood year, yearling summer Chinook were acclimated at both Turtle Rock Fish Hatchery and the Chelan River net pens. With the conversion of the subyearling program to a yearling program and the reduction of the NNI component to 176,000 , the current goal is to release 576,000 yearling summer Chinook smolts ( 176,000 from the NNI program plus 400,000 from the converted subyearling program). Beginning in 2012, the 576,000 yearlings are acclimated overwinter at facilities at Chelan Hatchery on Chelan River water. In 2012, the Turtle Rock program officially became the Chelan Falls summer Chinook program.
Over $90 \%$ of yearling summer Chinook have been marked with CWTs and all are ad-clipped. In addition, juvenile summer Chinook were PIT tagged within each of the circular and standard raceways.

### 11.1 Broodstock Sampling

Before 2013, broodstock for the program were collected as part of the Wells summer Chinook volunteer program. Refer to Snow et al. (2012) for information related to adults collected for those programs. Beginning in 2013, broodstock collection for the Chelan Falls program was piloted at the Eastbank Hatchery Outfall and at the outlet structure of the water conveyance canal for the Chelan Tailrace Pump Station. This section focuses on results from sampling broodstock from 2013 to present.

## Origin of Broodstock

Broodstock collected in 2013-2016 consisted entirely of hatchery-origin summer Chinook (Table 11.1). A total of 85 hatchery-origin Chinook collected from Chief Joseph Fish Hatchery were surplused from the 2015 brood year.
Table 11.1. Numbers of wild and hatchery summer Chinook collected for broodstock, numbers that died before spawning, and numbers of Chinook spawned for the Chelan Falls summer Chinook program during 2013-2016. Unknown origin fish (i.e., undetermined by scale analysis, no CWT or fin clips, and no additional hatchery marks) were considered naturally produced. Mortality includes fish that died of natural causes typically near the end of spawning and were not needed for the program and surplus fish killed at spawning.

| Brood year | Wild summer Chinook |  |  |  |  | Hatchery summer Chinook |  |  |  |  | Total number spawned |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Number collected | Prespawn loss $^{\text {a }}$ | Mortality | Number spawned | Number released | Number collected | Prespawn loss $^{\text {a }}$ | Mortality | Number spawned | Number released |  |
| 2013 | - | - | - | - | - | 318 | 4 | 0 | 314 | 0 | 314 |
| 2014 | - | - | - | - | - | 331 | 19 | 15 | 297 | 0 | 297 |
| 2015 | - | - | - | - | - | 351 | 17 | $14^{\text {b }}$ | 320 | 0 | 320 |
| 2016 | - | - | - | - | - | 350 | 5 | 1 | 344 | 0 | 344 |
| Average | - | - | - | - | - | 338 | 11 | 8 | 319 | 0 | 319 |
| Median | - | - | - | - | - | 341 | 11 | 8 | 317 | 0 | 317 |

${ }^{\text {a }}$ Pre-spawn loss represents the number of fish that died during the holding period before spawning. Mortality is the number of fish that were surplused following spawning.
${ }^{\mathrm{b}}$ There was an additional 85 fish surplused that were excess from collections at Chief Joseph Fish Hatchery and were not included in mortality estimates.

## Age/Length Data

Ages of summer Chinook broodstock were determined from analysis of scales and/or CWTs. Broodstock collected from the 2014 return consisted primarily of age-4 and 5 hatchery-origin Chinook ( $99 \%$ ). Age- 3 hatchery-origin fish made up $1 \%$ of the broodstock (Table 11.2).

Broodstock collected from the 2015 return consisted primarily of age-4 and 5 hatchery-origin Chinook ( $97.3 \%$ ). Age-3 hatchery-origin Chinook made up $2.3 \%$ of the broodstock. Age-6 hatchery-origin Chinook made up $0.3 \%$ of the broodstock (Table 11.2).
Broodstock collected from the 2016 return consisted primarily of age-4 and 5 natural-origin Chinook ( $98.7 \%$ ). Age-3 natural-origin Chinook made up $0.6 \%$ of the broodstock (Table 11.2).

Table 11.2. Percent of hatchery and wild summer Chinook of different ages (total age) collected from broodstock for the Chelan Falls summer Chinook program, 2013-2016.

| Return Year | Origin | Total age |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | 2 | 3 | 4 | 5 | 6 |
| 2013 | Wild | -- | -- | -- | -- | -- |
|  | Hatchery | 0.0 | 0.0 | 37.0 | 62.0 | 1.0 |
| 2014 | Wild | -- | -- | -- | -- | -- |
|  | Hatchery | 0.0 | 0.0 | 37.0 | 62.0 | 1.0 |
| 2015 | Wild | -- | -- | -- | -- | -- |
|  | Hatchery | 0.0 | 2.3 | 53.8 | 43.5 | 0.3 |
| 2016 | Wild | -- | -- | -- | -- | -- |
|  | Hatchery | 0.0 | 0.0 | 35.4 | 64.0 | 0.7 |
| Average | Wild | -- | -- | -- | -- | -- |
|  | Hatchery | 0 | 0.6 | 40.8 | 57.9 | 0.8 |
| Median | Wild | -- | -- | -- | -- | -- |
|  | Hatchery | 0 | 0 | 37 | 62 | 0.85 |

Mean lengths of hatchery-origin summer Chinook of a given age differed little among return years 2013-2016 (Table 11.3).

Table 11.3. Mean fork length (cm) at age (total age) of hatchery and wild summer Chinook collected from broodstock for the Chelan Falls program, 2013-2016; $\mathrm{N}=$ sample size and $\mathrm{SD}=1$ standard deviation.

## Sex Ratios

Male summer Chinook in the 2014 broodstock made up about $50.8 \%$ of the adults collected, resulting in an overall male to female ratio of 1.03:1.00 (Table 11.4.). In 2015, males made up about $46.0 \%$ of the adults collected, resulting in an overall male to female ratio of 0.85:1.00 (Table 11.4). In 2016, males made up about $50.6 \%$ of the adults collected, resulting in an overall male to female ratio of 1.02:1.00 (Table 11.4). The ratios for 2014 and 2016 broodstock were above the
assumed 1:1 ratio goal in the broodstock protocol. The ratios for 2015 broodstock were below the assumed 1:1 ratio goal in the broodstock protocol.
Table 11.4. Numbers of male and female wild and hatchery summer Chinook collected for broodstock at for the Chelan Falls program, 2013-2016. Ratios of males to females are also provided.

| Return <br> year | Number of wild summer Chinook |  |  | Number of hatchery summer Chinook |  |  | Total M/F <br> ratio |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Males (M) | Females (F) | $\mathbf{M / F}$ | Males (M) | Females (F) | $\mathbf{M} / \mathbf{F}$ |  |
| 2013 | - | - | - | 160 | 158 | $1.01: 1.00$ |  |
| 2014 | - | - | - | 168 | 163 | $1.03: 1.00$ | $1.03: 1.00$ |
| 2015 | - | - | - | 149 | 175 | $0.85: 1.00$ | $0.85: 1.00$ |
| 2016 | - | - | - | 177 | 173 | $1.02: 1.00$ | $1.02: 1.00$ |
| Total | - | - | - | $\mathbf{6 5 4}$ | $\mathbf{6 6 9}$ | $\mathbf{0 . 9 8 : 1 . 0 0}$ | $\mathbf{0 . 9 8 : 1 . 0 0}$ |

## Fecundity

Fecundities for the 2014, 2015, and 2016 summer Chinook broodstock averaged 4,275, 3,597, and 4,008 eggs per female, respectively (Table 11.5). These values are close to the overall average of 4,086 eggs per female. Mean observed fecundities for the 2014-2016 returns were below the expected fecundity of $4,475,4,372$, and 4,372 eggs per female assumed in the broodstock protocol, respectively.
Table 11.5. Mean fecundity of wild, hatchery, and all female summer Chinook collected for broodstock for the Chelan Falls program, 2013-2016; NA = not available.

| Return year | Mean fecundity |  |  |
| :---: | :---: | :---: | :---: |
|  | Wild | Hatchery | Total |
| 2013 | - | 4,462 | 4,462 |
| 2014 | - | 4,275 | 4,275 |
| 2015 | - | 3,597 | 3,597 |
| 2016 | - | 4,008 | 4,008 |
| Average | - | $\mathbf{4 , 0 8 6}$ | $\mathbf{4 , 0 8 6}$ |
| Median | - | $\mathbf{4 , 1 4 2}$ | $\mathbf{4 , 1 4 2}$ |

* Individual fecundities were not assigned to females until 1997 brood.

### 11.2 Hatchery Rearing

## Rearing History

## Number of eggs taken

Based on the unfertilized egg-to-release standard of $81 \%$, a total of 688,995 eggs were needed to meet the program goal of 576,000 smolts for brood years 2012 and 2013. An evaluation of the program in 2014 concluded that 696,493 eggs were needed to attain the 576,000 smolts. From 2013-2016, the egg take goal has not been reached (Table 11.6).

Table 11.6. Numbers of eggs taken from summer Chinook broodstock for the Chelan Falls program, 2013-2016.

| Return year | Number of eggs taken |
| :---: | :---: |
| 2013 | 696,131 |
| 2014 | 618,092 |
| 2015 | 573,144 |
| 2016 | 680,448 |
| Average | $\mathbf{6 4 1 , 9 5 4}$ |
| Median | $\mathbf{6 4 9 , 2 7 0}$ |

## Number of acclimation days

Rearing of the 2014 brood Chelan Falls summer Chinook was similar to previous years with fish being held on well water at Eastbank Hatchery until transfer to the Chelan Falls Acclimation Facility for overwinter acclimation. This was the fourth year that the whole program was transferred to the Chelan Falls Acclimation Facility for final overwinter acclimation on Chelan River water. Transfer occurred on 2-4 November 2014. Fish were volitionally released from 1518 April 2016 after 163-168 days of acclimation (Table 11.7).
Table 11.7. Number of days Chelan summer Chinook were acclimated at Chelan Falls Acclimation Facility, brood years 2013-2014.

| Brood year | Release year | Transfer date | Release date | Number of days |
| :---: | :---: | :---: | :---: | :---: |
| 2013 | 2015 | $3-6 \mathrm{Nov}$ | 15 Apr | $160-163$ |
| 2014 | 2016 | $2-4-\mathrm{Nov}$ | $15-18-\mathrm{Apr}$ | $163-168$ |

## Release Information

## Numbers released

The subyearling Turtle Rock summer Chinook program was discontinued in 2010; however, releases of subyearling Chinook in past years are shown in Tables 11.8 and 11.9. Production from the subyearling programs was converted to the yearling program.
The 2014 yearling summer Chinook program achieved $80.8 \%$ of the 576,000 goal with about 465,450 fish being released from the Chelan River Acclimation Ponds (Table 11.10).
Table 11.8. Numbers of Turtle Rock summer Chinook subyearlings released from the hatchery, brood years 1995-2009. The release target for Turtle Rock summer Chinook subyearlings was 810,000 fish.

${ }^{\text {a }}$ No CWT mark rate was provided because of the early release of this group.

## Numbers tagged

Brood year 2014 yearling Chinook were $99.0 \%$ CWT and $99.4 \%$ adipose fin-clipped.
In 2017, a total of 10,103 Chelan River summer Chinook (brood 2015) were tagged at Chelan Falls Hatchery on 13-16 March (Table 11). These were tagged and released into water-reuse circular
ponds. Fish were not fed during tagging or for two days before and after tagging. Fish averaged 133-137 mm in length and 25-26 g at time of tagging.
Table 11.11 summarizes the number of yearling summer Chinook that have been PIT-tagged and released from the Turtle Rock/Chelan Falls Program.
Table 11.11. Summary of PIT-tagging activities for Turtle Rock/Chelan Falls yearling summer Chinook, brood years 2007-2014; fpp = fish per pound.

| Brood year | Release year | Raceway/Program | Number of fish tagged | Number of tagged fish that died | Number of tags shed | Number of tagged fish released |

## Fish size and condition at release

Although the subyearling summer Chinook program was discontinued, sizes of subyearlings released from Turtle Rock Hatchery before 2010 are shown in Tables 11.12 and 11.13.
Table 11.12. Mean lengths (FL, mm), weight ( g and fish/pound), and coefficient of variation (CV) of Turtle Rock summer Chinook subyearlings released from the hatchery, brood years 1995-2009. Size targets are provided in the last row of the table.

| Brood year | Release year | Fork length (mm) |  | Mean weight |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Mean | $\mathbf{C V}$ | Grams (g) | Fish/pound |
| 1995 | 1996 | 102 | 6.3 | 12.6 | 36 |
| 1996 | 1997 | 87 | 8.0 | 7.4 | 62 |
| 1997 | 1998 | 98 | 6.2 | 10.2 | 45 |
| 1998 | 1999 | 96 | 6.3 | 10.7 | 43 |

| Brood year | Release year | Fork length (mm) |  | Mean weight |  |

${ }^{\text {a }}$ For size-target studies, fish per pound (fpp) targets for brood year 2012 were 10, 13, 18, 22 fpp .

## Survival Estimates

## Normal subyearling releases

Overall survival of the normal subyearling Turtle Rock summer Chinook program from green egg to release was below the standard set for the program (Table 11.15). Lower than expected survival
at ponding and post-ponding reduced the overall program performance. This program was discontinued in 2010.

Table 11.15. Hatchery life-stage survival rates (\%) for Turtle Rock subyearling (zero program) summer Chinook, brood years 2004-2009. Survival standards or targets are provided in the last row of the table.

## Accelerated subyearling releases

Overall survival of the accelerated subyearling Turtle Rock summer Chinook program from green egg to release was below the standard set for the program (Table 11.16). Lower than expected survival in post-ponding reduced the overall program performance. This program was discontinued in 2010.

Table 11.16. Hatchery life-stage survival rates (\%) for Turtle Rock subyearling (accelerated program) summer Chinook, brood years 2004-2009. Survival standards or targets are provided in the last row of the table.

${ }^{\text {a }}$ The 2008 brood year was the last year of the accelerated subyearling program.

## Yearling releases

Overall survival of the 2014 brood yearling Chelan Falls summer Chinook program from green egg to release was below the standard set for the program (Table 11.17). This is largely because of lower unfertilized egg to eyed egg and eyed egg to ponding survival.

Table 11.17. Hatchery life-stage survival rates (\%) for Turtle Rock/Chelan Falls yearling summer Chinook, brood years 2004-2014. Survival standards or targets are provided in the last row of the table.

### 11.3 Spawning Surveys

Surveys for summer Chinook redds in the Chelan River were conducted from late September to late-November 2016. Total redd counts were conducted in the river (see Appendix O for more details).

## Redd Counts

A total of 448 summer Chinook redds were counted in the Chelan River in 2016 (Table 11.18). This was higher than the overall average of 305 redds.
Table 11.18. Total number of redds counted in the Chelan River, 2000-2016.

| Survey year | Total redd count |
| :---: | :---: |
| 2000 | 196 |
| 2001 | 240 |
| 2002 | 253 |
| 2003 | 173 |

| Survey year | Total redd count |
| :---: | :---: |
| 2004 | 185 |
| 2005 | 179 |
| 2006 | 208 |
| 2007 | 86 |
| 2008 | 153 |
| 2009 | 246 |
| 2010 | 398 |
| 2011 | 413 |
| 2012 | 426 |
| 2013 | 729 |
| 2014 | 400 |
| 2015 | 448 |
| 2016 | 448 |
| Average | 305 |
| Median | 246 |

## Redd Distribution

Summer Chinook redds were not evenly distributed among the four sampling areas within the Chelan River. Most redds ( $46 \%$ ) were located in the Chelan Tailrace (Table 11.19). Fewer summer Chinook spawned in the Habitat Pool and Columbia Tailrace.
Table 11.19. Total number of summer Chinook redds counted in different survey areas within the Chelan River during September through early November 2016.

| Survey area | Total redd count | Percent |
| :---: | :---: | :---: |
| Chelan Tailrace | 207 | 46 |
| Columbia Tailrace | 74 | 16 |
| Habitat Channel | 106 | 24 |
| Habitat Pool | 61 | 14 |
| Totals | $\mathbf{4 4 8}$ | $\mathbf{1 0 0}$ |

## Spawn Timing

Spawning in 2016 began the first week of October, peaked mid-October, and ended midNovember. Peak spawning occurred in the Habitat Pool in early October and during mid-October in the Chelan Tailrace, Habitat Channel, and Columbia Tailrace (Figure 11.1).

## Chelan River Summer Chinook

Figure 11.1. Number of new summer Chinook redds counted during different weeks within different sections of the Chelan River, September through November 2016.

## Spawning Escapement

Spawning escapement for summer Chinook in the Chelan River was calculated as the total number of redds times the fish per redd ratio estimated from fish sampled at Wells Dam. ${ }^{33}$ The estimated fish per redd ratio for Methow summer Chinook in 2016 was 2.01 . Multiplying this ratio by the number of redds counted in the Chelan River resulted in a total spawning escapement of 900 summer Chinook (Table 11.20).
Table 11.20. Spawning escapements for summer Chinook in the Chelan River for return years 20002016.

| Return year | Fish/Redd | Redds | Total spawning <br> escapement |
| :---: | :---: | :---: | :---: |
| 2000 | 2.40 | 196 | 470 |
| 2001 | 4.10 | 240 | 984 |
| 2002 | 2.30 | 253 | 582 |
| 2003 | 2.42 | 173 | 419 |
| 2004 | 2.25 | 185 | 416 |
| 2005 | 2.93 | 179 | 524 |
| 2006 | 2.02 | 208 | 420 |
| 2007 | 2.20 | 86 | 189 |
| 2008 | 3.25 | 153 | 497 |

| Median | $\mathbf{2 . 5 4}$ | $\mathbf{2 4 6}$ | $\mathbf{6 2 5}$ |

### 11.4 Carcass Surveys

Surveys for summer Chinook carcasses within the Chelan River were conducted during late September to mid-November 2016 (see Appendix O for more details).

## Number sampled

A total of 253 summer Chinook carcasses were sampled during September through late-November in the Chelan River (Table 11.21). This was higher than the overall average of 178 carcasses sampled since 2000.
Table 11.21. Numbers of summer Chinook carcasses sampled within each survey area within the Chelan River, 2000-2016; ND = no data.

## Carcass Distribution and Origin

Summer Chinook carcasses were not evenly distributed among survey areas within the Chelan River in 2016 (Table 11.22). Most of the carcasses in the Chelan River were found in the Columbia Tailrace.

In 2016, hatchery and wild summer Chinook carcasses were not distributed equally among the survey areas within the Chelan River (Table 11.22; Figure 11.2). A larger percentage of hatchery carcasses occurred in the Columbia Tailrace, Habitat Channel, and Habitat Pool, while a larger percentage of wild summer Chinook carcasses occurred in the Chelan Tailrace. There was a larger sample size of hatchery than wild summer Chinook carcasses in the Chelan River in 2016.
Table 11.22. Numbers of wild and hatchery summer Chinook carcasses sampled within different survey areas on the Chelan River, 2000-2016; ND = no data.

Chelan River Summer Chinook

Figure 11.2. Average distribution of wild and hatchery produced carcasses in different survey areas within the Chelan River, 2013-2016.

## Sampling Rate

Overall, $28 \%$ of the total spawning escapement of summer Chinook in the Chelan River was sampled in 2016 (Table 11.16). Sampling rates among survey reaches varied from 6 to $86 \%$.
Table 11.23. Number of redds and carcasses, total spawning escapement, and sampling rates for summer Chinook in the Chelan River, 2016.

| Survey reach | Total number of <br> redds | Total number of <br> carcasses | Total spawning <br> escapement | Sampling rate |

| Habitat Pool | $62.5(6.6)$ | $67.4(5.7)$ |
| Total | $\mathbf{6 2 . 2}(7.8)$ | $\mathbf{6 7 . 7}(4.9)$ |

### 11.5 Life History Monitoring

Life history characteristics of Chelan Falls and Turtle Rock summer Chinook were assessed by examining carcasses on spawning grounds and by reviewing tagging data and fisheries statistics.

## Contribution to Fisheries

## Normal subyearling releases

Most of the harvest on Turtle Rock summer Chinook (normal subyearling releases) occurred in the Ocean (10-100\% of the fish harvested; Table 11.25). Brood years 1995 and 2006 provided the largest total harvests, while brood year 1997 and 1998 provided the lowest. The subyearling hatchery program was discontinued after brood year 2009.

Table 11.25. Estimated number and percent (in parentheses) of Turtle Rock summer Chinook (normal subyearling releases) captured in different fisheries, brood years 1995-2009.

| Brood year | Ocean fisheries | Columbia River Fisheries |  |  | Total |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Tribal | Commercial <br> (Zones 1-5) | Recreational <br> (sport) |  |

## Accelerated subyearling releases

Most of the harvest on Turtle Rock summer Chinook (accelerated subyearling releases) occurred in ocean fisheries (Table 11.26). Ocean harvest has made up $0 \%$ to $100 \%$ of all Turtle Rock summer Chinook harvested. Brood year 1999 provided the largest total harvest, while brood years 1995, 1997, 2002, and 2003 provided the lowest. This program was discontinued after brood year 2008.

Table 11.26. Estimated number and percent (in parentheses) of Turtle Rock summer Chinook (accelerated subyearling releases) captured in different fisheries, brood years 1995-2008.

| Brood year | Ocean fisheries | Columbia River Fisheries |  |  | Total |
| :---: | :---: | :---: | :---: | :---: | :---: |

## Yearling releases

Most of the harvest on Turtle Rock/Chelan Falls summer Chinook (yearling releases) occurred in ocean fisheries (Table 11.27). Ocean harvest has made up $39 \%$ to $95 \%$ of all Turtle Rock summer Chinook harvested. Brood years 1998, 2008, and 2010 provided the largest harvest, while brood years 1995 and 1996 provided the lowest.
Table 11.27. Estimated number and percent (in parentheses) of Turtle Rock/Chelan Falls summer Chinook (yearling releases) captured in different fisheries, brood years 1995-2010.

| Brood year | Ocean fisheries | Columbia River Fisheries |  |  | Total |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Tribal | Commercial (Zones 1-5) | Recreational (sport) |  |

## Straying

## Normal subyearling releases

Assessment of straying was based on evaluating the location of CWT recoveries. There were 17 tag codes used to differentiate Turtle Rock/Chelan normal subyearling releases by brood year, release type, and location. There was one subyearling group released into the Chelan River in 2010 (brood year 2009). There were also six non-associated releases. ${ }^{34}$ All tag codes, except brood year 2009, recovered in the Chelan River or other tributaries in the Upper Columbia were considered strays.
Rates of Turtle Rock summer Chinook (normal subyearling releases) straying into spawning areas in the upper basin have been low. Although Turtle Rock summer Chinook have strayed into other spawning areas, they made up less than $10 \%$ of the spawning escapement within those areas (Table 11.28). The Chelan tailrace has received the largest number of Turtle Rock strays. This hatchery program was discontinued after brood year 2009.
Table 11.28. Number (No.) and percent of spawning escapements within other non-target basins that consisted of Turtle Rock summer Chinook (normal subyearling releases), return years 1998-2015. For example, for return year 2003, $0.6 \%$ of the summer Chinook spawning escapement in the Okanogan River basin consisted of Turtle Rock summer Chinook. Percent strays should be less than $10 \%$.

On average, about $29 \%$ of the brood year returns have strayed into spawning areas in the upper basin (Table 11.29). Depending on brood year, percent strays into spawning areas have ranged from $0-100 \%$. Few ( $2.3 \%$ on average) have strayed into non-target hatchery programs.
Table 11.29. Number and percent of Turtle Rock summer Chinook (normal subyearling releases) that homed to the target hatchery and strayed to non-target spawning areas and non-target hatchery programs, by brood years 1995-2009.

* Homing to the target hatchery includes Turtle Rock hatchery fish that were captured and included as broodstock in the Turtle Rock Hatchery program. These hatchery fish were typically collected at Wells Dam and Wells Hatchery.

## Accelerated subyearling releases

Assessment of straying was based on evaluating the location of CWT recoveries. There were 16 tag codes used to differentiate Turtle Rock accelerated subyearling releases by brood year and release type. There were also four non-associated releases. All tag codes recovered in the Chelan River or other tributaries in the Upper Columbia were considered strays.

Rates of Turtle Rock summer Chinook (accelerated subyearling releases) straying into spawning areas in the upper basin have been low. Although Turtle Rock summer Chinook have strayed into other spawning areas, they made up less than $10 \%$ of the spawning escapement within those areas
(Table 11.30). The Chelan tailrace, Entiat Basin, and Methow River basin have received the largest numbers of Turtle Rock strays. This hatchery program was discontinued after brood year 2008.

Table 11.30. Number (No.) and percent of spawning escapements within other non-target basins that consisted of Turtle Rock summer Chinook (accelerated subyearling releases), return years 1998-2014. For example, for return year 2001, $0.2 \%$ of the summer Chinook spawning escapement in the Methow River basin consisted of Turtle Rock summer Chinook. Percent strays should be less than $10 \%$.

* Homing to the target hatchery includes Turtle Rock hatchery fish that were captured and included as broodstock in the Turtle Rock Hatchery program. These hatchery fish were typically collected at Wells Dam and Wells Hatchery.

## Yearling releases

Assessment of straying was based on evaluating the location of CWT recoveries. Yearlings have been released in the Columbia River and in the Chelan River. There were 16 tag codes used to differentiate Turtle Rock yearling releases by brood year, release type, and location. All these fish were released into the Columbia River and therefore any tag recoveries in the Chelan River or other tributaries were considered strays. In contrast, there were 21 tag codes ${ }^{35}$ used to differentiate Chelan River yearling releases by brood year, release type, and location (there were four nonassociated releases). All these fish were released into the Chelan River and therefore any tag recoveries in tributaries other than the Chelan River were considered strays.

Rates of Turtle Rock/Chelan Falls summer Chinook (yearling releases) straying into spawning areas in the upper basin have varied widely depending on spawning area. Most of these fish strayed to spawning areas within the Chelan tailrace (Turtle Rock released fish), Entiat Basin, and Methow River basin. On average, Turtle Rock summer Chinook have made up 4-13\% of the spawning escapement within those basins (Table 11.32). Relatively few, on average, have strayed to spawning areas in the Okanogan River basin, Wenatchee River basin, and the Hanford Reach (i.e., they made up less than $2 \%$ of the spawning escapement in these areas).

[^32]Table 11.32. Number (No.) and percent of spawning escapements within other non-target basins that consisted of Turtle Rock/Chelan Falls summer Chinook (yearling releases), return years 1998-2015. For example, for return year 2003, $4.3 \%$ of the summer Chinook spawning escapement in the Methow River basin consisted of Turtle Rock summer Chinook. Percent strays should be less than $10 \%$.

${ }^{a}$ Homing to the target hatchery includes Turtle Rock/Chelan Hatchery fish that were captured and included as broodstock in the Turtle Rock/Chelan Hatchery program. These hatchery fish are typically collected at Wells Dam, Wells Hatchery, and the Eastbank Hatchery Outfall.
${ }^{\mathrm{b}}$ Summary statistics for yearling Turtle Rock summer Chinook released into the Columbia River (brood years 1995-2004).
${ }^{\text {c }}$ Summary statistics for yearling Turtle Rock/Chelan River summer Chinook released into the Chelan River (brood years 2005 to present).

## Post-Release Survival and Travel Time

We used PIT-tagged fish to estimate survival rates and travel times (arithmetic mean days) of hatchery summer Chinook from the Turtle Rock/Chelan River release sites to McNary Dam, and smolt to adult ratios (SARs) from release to detection at Bonneville Dam (Table 11.34). ${ }^{36}$ Over the seven brood years for which PIT-tagged hatchery fish were released, survival rates from the release sites to McNary Dam ranged from 0.423 to 0.798 ; SARs from release to detection at Bonneville Dam ranged from 0.010 to 0.028 . Average travel times from release sites to McNary Dam ranged from 15 to 33 days.
Much of the variation in survival rates and travel time among brood years resulted from releases of different experimental groups (Table 11.34). For example, brood years 2007 and 2008 were each split into two experimental groups (Circular Reuse group and Standard Raceway group). For both brood years, survival from the release site to McNary Dam and SARs were greater for the Circular Reuse fish than for the Standard Raceway fish. For both brood years, travel time from

[^33]release to McNary Dam appeared to be longer for the Standard Raceway fish than for the Circular Reuse fish.

Another experiment was conducted with brood years 2012, 2013, and 2014 (Table 11.34). These brood years were split into different treatment groups based on fish size. Based on available information, there were no clear differences in survival rates and travel times to McNary Dam among the different experimental groups. SARs for these fish will be calculated after all fish have returned to the Columbia River.

Table 11.34. Total number of Turtle Rock/Chelan Falls yearling summer Chinook released with PIT tags, their survival and travel times (mean days) to McNary Dam, and smolt-to-adult (SAR) ratios for brood years 2007-2014. Standard errors are shown in parentheses. NA = not available (i.e., not all the fish from the release groups have returned to the Columbia River); $\mathrm{fpp}=$ fish per pound.

* Brood year 2011 experienced high mortality due to fungus, bacterial cold-water disease, bacterial gill disease, and erythrocytic inclusion body syndrome during April 2013.

## Smolt-to-Adult Survivals

Subyearling-to-adult and smolt-to-adult survival ratios (SARs) were calculated as the number of hatchery adult recaptures divided by the number of tagged hatchery subyearling or yearling Chinook released. For these analyses, SARs were based on CWT returns.

## Normal subyearling releases

For the available brood years, SARs for normal subyearling-released Chinook have ranged from 0.000036 to 0.001886 (Table 11.35). This hatchery program was discontinued after brood year 2009.

## Accelerated subyearling releases

For the available brood years, SARs for accelerated subyearling-released Chinook have ranged from 0.000011 to 0.004614 (Table 11.36). This hatchery program was discontinued after brood year 2008.
Table 11.36. Subyearling-to-adult ratios (SARs) for Turtle Rock accelerated subyearling-released summer Chinook, brood years 1995-2008.

### 11.6 ESA/HCP Compliance

## Broodstock Collection

The 2014 brood Chelan Falls (formerly Turtle Rock) summer Chinook program was supported through adult collections at the Eastbank outfall and surplus adults from Chief Joe Hatchery. During 2014, broodstock collections at the Eastbank outfall were consistent with the 2014 Upper Columbia River Salmon and Steelhead Broodstock Objectives and site-based broodstock collection protocols as required in ESA permit 1347. The 2014 collection target totaled 312 summer Chinook. Actual 2014 broodstock collection was 331 adults.

## Hatchery Rearing and Release

The brood year 2014 release totaled 465,450 yearling fish. These releases represented $80.8 \%$ of the 576,000 Rocky Reach HCP and ESA Section 10 Permit 1347 production for the Chelan Falls yearling summer Chinook production. Lower than expected fertilization rates ( $83.6 \%$ ) followed by eyed-egg to ponding survival were the primary factors in not meeting the release goal.

## Hatchery Effluent Monitoring

Per ESA Permits 1196, 1347, 1395, 18118, 18120, and 18121, permit holders shall monitor and report hatchery effluents in compliance with applicable National Pollution Discharge Elimination Systems (NPDES) (EPA 1999) permit limitations. There were no NPDES violations reported at PUD Hatchery facilities during the period 1 January through 31 December 2016. NPDES monitoring and reporting for Chelan PUD Hatchery Programs during 2016 are provided in Appendix F.

## Appendix A

Abundance and Total Numbers of Chinook Salmon and Trout in the Chiwawa River basin, Washington, 2016

January 25, 2017

TO: HCP Hatchery Committee
FROM: Tracy Hillman
Subject: Abundance and Total Numbers of Chinook Salmon and Trout in the Chiwawa River basin, Washington, 2016

The Chelan County Public Utility District (PUD) hatchery program is operated through a habitat conservation plan (HCP) that was incorporated into the PUD's license in 2004. The HCP directed the signatories to develop a monitoring and evaluation plan within one year of the effective date. This resulted in the development of the Conceptual Approach to Monitoring and Evaluating the Chelan County Public Utility District Hatchery Programs (Murdoch and Peven 2005). In 2013, the Hatchery Committees updated the hatchery monitoring and evaluation plan (Hillman et al. 2013). This study will help the Hatchery Committees determine if it is meeting Objective 2 in the updated monitoring and evaluation plan.
Objective 2: Determine if the proportion of hatchery fish on the spawning grounds affects the freshwater productivity of supplemented stocks.
We estimated densities and total numbers of age-0 spring Chinook salmon Oncorhynchus tshawytscha, trout Oncorhynchus sp., and char Salvelinus sp. in the Chiwawa River basin, Washington, in August 2016. This was the $24^{\text {th }}$ year of an ongoing study to assess the freshwater productivity (juveniles/redd) of Chinook salmon in the Chiwawa River basin. We used landscape classification to stratify streams in the basin that supported juvenile Chinook salmon (Hillman and Miller 2004). Classification "explained" most of the variability in fish numbers caused by geology, land type, valley bottom type, stream state condition, and habitat type. We identified ten reaches on the lower 31 miles ( 50 km ) of the Chiwawa River and one reach in each of Phelps, Rock, Chikamin, Big Meadow, Alder, Brush, Clear, Y, and Unnamed ${ }^{1}$ creeks (Figure 1). Each reach consisted of several combinations of state-type and habitat-type strata. We used classification to find reference areas for reaches in the Chiwawa River. We matched Reach 3 and Reach 8 of the Chiwawa River with a moderately-confined section of Nason Creek (RM 0.621.70 ) and an unconfined area of the Little Wenatchee River (RM 4.39-8.55), respectively

[^34](Hillman and Miller 2004). Because of the supplementation program in Nason Creek, the use of Nason Creek as a reference for the Chiwawa River is no longer valid. However, as directed by the Hatchery Committee, we continue to sample sites in Nason Creek. Following methods described in Hillman and Miller (2004), we used underwater observations to estimate numbers of fish in 187 randomly selected sites.

During sampling in August 2016, discharge in the Chiwawa River averaged 202 cubic feet per second (cfs) and ranged from 126-325 cfs (Figure 2). Stream temperatures during the study period ranged from 8.0 to $18.0^{\circ} \mathrm{C}$. Fish species observed in the Chiwawa River basin and reference areas during the 1992-2016 survey period ${ }^{2}$ included: spring Chinook salmon, coho salmon $O$. kisutch, sockeye salmon O. nerka, steelhead/rainbow trout O. mykiss (hatchery rainbow were present only in 1992 and 1993), cutthroat trout $O$. clarki lewisi, bull trout $S$. confluentus, brook trout $S$. fontinalis, mountain whitefish Prosopium williamsoni, dace Rhinichthys sp., northern pikeminnow Ptychocheilus oregonensis, suckers Catostomus sp., and sculpin Cottus sp. The age-0 spring Chinook that we observed in the Chiwawa River basin during the 2016 survey were produced from 543 redds counted in the fall of 2015 (Hillman et al. 2016). Assuming a mean fecundity of 4,847 eggs per female Chinook (from females collected for broodstock), and that no female produced more than one redd (Murdoch et al. 2009), we estimated that the Chiwawa River basin was seeded with 2,631,921 eggs in 2015 (Appendix A).
In 2016, riffles made up the largest fraction of habitat types in reaches of the Chiwawa River basin (54\% of the total stream surface area) (Table 1). Pools (24\%), glides (6\%), and multiple channels ( $16 \%$ ) constituted the remaining $46 \%$ of the stream surface area. We found woody debris associated with most multiple-channel habitat.

## Chinook Salmon Abundance

Chinook salmon were the most abundant salmonid in the Chiwawa River basin. We estimated, based on surface area, that age-0 Chinook salmon numbered 140,172 ( $\pm 10 \%$ of the estimated total) in the Chiwawa River basin in August 2016 (Table 2). Extrapolating based on volume of habitat types, age-0 Chinook numbered 137,525 ( $\pm 13 \%$ ) in the Chiwawa River basin. About 3\% of the juvenile Chinook were in tributaries to the Chiwawa River. During the 1992-2016 surveys, numbers of age-0 Chinook ranged from 5,815 to 149,563 in the Chiwawa River basin (Figure 3; Appendix A and B). Most of the difference in juvenile numbers among years resulted from different seeding (stock) levels (Figure 4). Numbers of Chinook redds in the Chiwawa River basin during 1992-2015 ranged from 13 to 1,078, resulting in seeding levels of 66,248 to 4,984,672 eggs (Appendix A).

As in most years, age-0 Chinook in 2016 were distributed contagiously among reaches in the Chiwawa River (Table 2). In the Chiwawa River, densities of age-0 Chinook were highest in the upper reaches (Reaches 7-10). The highest densities in the Chiwawa River basin were in tributaries to the Chiwawa River (Table 2). Age-0 Chinook were most abundant in multiple channels and least abundant in glides and riffles. We found the majority of the Chinook

[^35]associated with woody debris in multiple channels (multiple channel use index $=2.83$ ) ${ }^{3}$. These sites (multiple channels) made up 16\% of the total surface area of the Chiwawa River basin, but they provided habitat for $56 \%$ of all the age-0 Chinook in the basin in 2016 (Appendix C). In contrast, riffles made up $54 \%$ of the total surface area, but provided habitat for only $8 \%$ of all age-0 Chinook in the Chiwawa River basin (riffle use index $=0.24$ ). Pools made up $24 \%$ of the total surface area and provided habitat for $35 \%$ of all age-0 Chinook in the basin (pool use index $=1.59$ ). Few Chinook used glides that lacked woody debris (glide use index $=0.25$ ).

As noted earlier, we assumed that the Chiwawa River was seeded with 2,631,921 Chinook eggs ( 543 redds times 4,847 eggs/female) in fall, 2015, and that at least 140,172 of those survived to August 2016. This means that the egg-to-parr survival was at least $5.3 \%$ ( $95 \%$ confidence bound 4.8-5.9\%). During 1992-2016, egg-to-parr survival averaged $8.0 \%$ (range 2.7-19.1\%) in the Chiwawa River basin (Appendix A). This survival rate comports with those from other streams. For example, Mullan et al. (1992) estimated an egg-to-parr survival rate of $9.8 \%$ for spring Chinook salmon in Icicle Creek, a tributary of the Wenatchee River. Using a Beverton and Holt model, Hubble (1993) estimated that egg-to-parr survival of Chinook in the Chewuck River, a tributary to the Methow River, ranged between $13 \%$ and $32 \%$, depending on percent seeding level in the basin. Kiefer and Forster (1991) estimated a mean egg-to-parr survival rate of 5.5\% (range 5.1-6.7\%) for naturally-spawning spring Chinook salmon in the entire upper Salmon River. They also noted that egg-to-parr survival of natural spawners and adult outplants in the headwater streams of the upper Salmon River averaged 24.4\% (range 16.1-32.0\%). Petrosky (1990) reported an egg-to-parr survival range of 1.2-29.0\% for Chinook in the upper Salmon River, Idaho. Konopacky et al. (1986) estimated egg-to-parr survival of Chinook in Bear Valley Creek, Idaho, as 8.1-9.4\%. Work by Richards and Cernera (1987) in Bear Valley Creek indicated an egg-to-parr survival of $2.1 \%$.

Mean densities of age-0 Chinook salmon in two reaches of the Chiwawa River were generally less than those in corresponding reference areas (Figure 5). Within both the Chiwawa River and its reference areas, pools and multiple channels consistently had the highest densities of age-0 Chinook.

We estimated a total of 282 ( $\pm 43 \%$ of the estimated total) age- $1+$ Chinook salmon in the Chiwawa River basin in August 2016 (Table 3). In August 1992-2016, numbers of age-1+ Chinook ranged from 5 to 967 in the Chiwawa River basin (Figure 3; Appendix B). These fish occurred throughout the Chiwawa River. We found relatively few age-1+ Chinook in tributaries; although, numbers in Big Meadow Creek were higher in 2015 than in past years. Age-1+ Chinook were most abundant in multiple channels and pools.

[^36]
## Juvenile Chinook Salmon Productivity (Fish/Redd)

Freshwater productivity of juvenile Chinook salmon was estimated as the number of parr (age-0 Chinook) per redd in the Chiwawa River basin. Theoretically, the relationship between number of parr and redds can be explained mathematically provided the relationship between the two parameters goes through the origin, increases monotonically at low spawning levels, and shows some level of density dependence at high spawning levels. We identified four alternative hypotheses that may explain the relationship between spawning level (redds) and numbers of age-0 Chinook:

1. The first hypothesis assumed that the number of juveniles increases constantly toward an asymptote as the number of redds increases. After the asymptote is reached, the number of juveniles neither increases nor decreases. The asymptote represents the maximum number of juveniles the system can support (i.e., carrying capacity for the system). This hypothesis was modeled with a Beverton-Holt curve that took the form:

$$
J=\frac{(\alpha R)}{(\beta+R)}
$$

where $\boldsymbol{J}$ is the number of juvenile (age- 0 ) Chinook, $\boldsymbol{R}$ is the number or redds, $\boldsymbol{\alpha}$ is the maximum number of juveniles produced, and $\boldsymbol{\beta}$ is the number of redds needed to produce (on average) juveniles equal to one-half the maximum number of juveniles.
2. The second hypothesis, like the first, assumed that the number of juveniles increases toward an asymptote (carrying capacity) as the number of redds increases. After the carrying capacity is reached, the number of juveniles neither increases nor decreases. The carrying capacity represents the maximum number of juveniles the system can support. This hypothesis was modeled with a smooth hockey stick function that took the form:

$$
J=J_{\infty}\left(1-e^{-\left(\frac{\alpha}{J_{\infty}}\right) R}\right)
$$

where $\boldsymbol{J}$ and $\boldsymbol{R}$ are as above, $\boldsymbol{\alpha}$ is the slope at the origin of the spawner-recruitment curve, and $\boldsymbol{J}_{\infty}$ is the carrying capacity of juveniles.
3. The third hypothesis assumed that the number of juveniles increases to a maximum and then declines as the number or redds increases. In this case, mortality rate of juveniles (or eggs) is proportional to the initial number of redds. Higher mortality rate is associated with density-dependent growth coupled with size-dependent predation. This hypothesis was modeled with a Ricker curve that took the form:

$$
J=\alpha R e^{-\beta R}
$$

where $\boldsymbol{J}$ and $\boldsymbol{R}$ are as above, $\boldsymbol{\alpha}$ is the number of juveniles per redd at low spawning levels, and $\boldsymbol{\beta}$ describes how quickly the juveniles per redd drop as the number of redds increases.
4. The fourth hypothesis, like the first, assumed that the number of juveniles increases constantly, but unlike the first, the number of juveniles does not reach an asymptote. Rather, the number of juveniles increases indefinitely, but at a slowing rate of increase. This hypothesis was modeled with both a Cushing curve and a Gamma function. The

Cushing curve took the form:

$$
\boldsymbol{J}=\boldsymbol{\alpha} \boldsymbol{R}^{\gamma}
$$

where $\boldsymbol{J}$ and $\boldsymbol{R}$ are as above, $\boldsymbol{\alpha}$ is the number of juveniles per redd at low spawning levels, and $\gamma$ describes the level of density dependence at high spawning levels. The Gamma function is a three-parameter model that has the form:

$$
J=\alpha R^{\gamma} e^{-\beta R}
$$

This is an un-normalized gamma function that is similar to the Cushing curve when $\beta=0$.
We used Akaike's Information Criterion for small sample size ( $\mathrm{AIC}_{\mathrm{c}}$ ) to determine which model(s) best explained the productivity of juvenile Chinook in the Chiwawa River basin. AIC ${ }_{c}$ was estimated as:

$$
A I C_{\mathrm{c}}=-2 \log (£(\theta \mid \text { data }))+2 K+\left(\frac{2 K(K+1)}{n-K-1}\right)
$$

where $\boldsymbol{\operatorname { l o g }}(\boldsymbol{£}(\boldsymbol{\theta} \mid$ data $))$ is the maximum likelihood estimate, $\boldsymbol{K}$ is the number of estimable parameters (structural parameters plus the residual variance parameter), and $\boldsymbol{n}$ is the sample size (Burnham and Anderson 2002). We used least-squares methods to estimate $\boldsymbol{\operatorname { l o g }}(\boldsymbol{£}(\boldsymbol{\theta} \mid \boldsymbol{d a t a})$ ), which was calculated as $\boldsymbol{\operatorname { l o g }}\left(\boldsymbol{\sigma}^{2}\right)$, where $\sigma^{2}=$ residual sum of squares divided by the sample size ( $\boldsymbol{\sigma}^{2}=\boldsymbol{R S S} / \boldsymbol{n}$ ). AIC $\mathrm{c}_{\mathrm{c}}$ assesses model fit in relation to model complexity (number of parameters). The model with the smallest $\mathrm{AIC}_{\mathrm{c}}$ value represents the "best approximating" model within the model set. Remaining models were ranked relative to the best model using AIC ${ }_{c}$ difference scores ( $\mathbf{\Delta} \mathbf{A I C} \mathbf{c}$ ), Akaike weights ( $\boldsymbol{w}_{\boldsymbol{i}}$ ), and evidence ratios. Models with $\boldsymbol{\Delta A I C} \mathbf{c}$ values less than 2 indicate that there is substantial support for these models as being the best-fitting models within the set (Burnham and Anderson 2002). Models with values greater than 2 have less support. Akaike weights are probabilities estimating the strength of the evidence supporting a particular model as being the best model within the model set. Models with small $\boldsymbol{w}_{i}$ values are less plausible as competing models (Burnham and Anderson 2002). If no single model could be specified as the best model, a "best subset" of competing models was identified using (1) AIC ${ }_{c}$ differences to indicate the level of empirical support each model had as being the best model, (2) evidence ratios based on Akaike weights to indicate the relative probability that any model is the best model, and (3) coefficients of determination $\left(R^{2}\right)$ assessing the explanatory power of each model.

The use of $\mathrm{AIC}_{\mathrm{c}}$ indicated that the Beverton-Holt model best approximated the information in the juveniles/redd data (Table 4; Figure 6). The estimated structural parameters for this model were:

$$
\text { Juveniles }=\frac{(152,439 \times \text { Redds })}{(191+\text { Redds })}
$$

where the bootstrap estimated standard errors for the two parameters were 17,210 and 56, respectively. The adjusted $R^{2}=0.84$. The second-best model was the smooth hockey stick model, which was $1.70 \mathrm{AIC}_{\mathrm{c}}$ units from the best model (Table 4; Figure 6). The estimated parameters for this model were:

$$
L N(\text { Juveniles })=11.7+L N\left(1-e^{-\left(\frac{715.9}{116,314}\right) \text { Redds }}\right)
$$

where the bootstrap estimated standard errors of the two parameters were 0.1 and 391, respectively, and the $R^{2}=0.83$. The $\mathrm{AIC}_{\mathrm{c}}$ difference scores, Akaike weights, and evidence ratios indicated that there was substantial support for both the Beverton-Holt and smooth hockey stick models (Table 4). There was less support for the remaining models (Ricker, Gamma ${ }^{4}$, and Cushing), which were $>2 \mathrm{AIC}_{c}$ units from the best models. This was further supported by the fact that, relative to the best models, the remaining models had evidence ratios greater than 10.

Although the Beverton-Holt, smooth hockey stick, and Ricker models have different biological assumptions, they all indicated a density-dependent relationship between spawning levels (redds) and juvenile Chinook production. This was not only evident in the best approximating models, but there was also a significant negative relationship between juveniles per redd and numbers of redds in the Chiwawa River basin (Figure 7). Although data at high seeding levels are lacking, the Beverton-Holt model estimates the population capacity ${ }^{5}$ of juvenile Chinook in the Chiwawa River basin at about 152,000 parr. This equates to about 1,197 Chinook parr per hectare. In contrast, the smooth hockey stick model, which fit the data as well as the Beverton-Holt model, estimates the population carrying capacity for juvenile Chinook at about 116,000 parr. This equates to about 913 Chinook parr per hectare. As a comparison, Thorson et al. (2013) estimated the carrying capacity for 15 populations of juvenile Chinook in the Snake River metapopulation as 5,000 juveniles per hectare. However, those authors noted that the estimate could be biased because of imperfect detectability and estimates of spawning numbers.

## Steelhead/Rainbow Abundance

Based on stream surface area, we estimated a total of 16,244 ( $\pm 14 \%$ of the estimated total) age-0 steelhead/rainbow ( $<4 \mathrm{in}$ ) in reaches of the Chiwawa River basin in August 2016 (Table 5). During the 1992-2016 survey period, numbers of age-0 steelhead/rainbow ranged from 1,410 to 45,727 in the Chiwawa River basin (Figure 8; Appendix B). In 1992-2016, numbers of age-0 steelhead/rainbow varied among reaches, but were typically highest in the lower reaches of the Chiwawa River. In all years they most often used riffle and multiple channel habitats in the Chiwawa River, although we also found them associated with woody debris in pool and glide habitat. In tributaries, they were generally most abundant in small pools. Those that we observed in riffles selected stations in quiet water behind small and large boulders or occupied stations in quiet water along the stream margin. In pool and multiple-channel habitats, we found age- 0 steelhead/rainbow using the same kinds of habitat as age-0 Chinook salmon.
We estimated that 4,031 ( $\pm 15 \%$ of the estimated total) age- $1+$ steelhead/rainbow (4-8 in) lived in reaches of the Chiwawa River basin in August 2016 (Table 6). During the survey period 1992-

[^37]2016, numbers of age-1+ steelhead/rainbow ranged from 754 to 22,130 (Figure 8; Appendix B). In most years, we found these fish in nearly all reaches, but they were typically most numerous in lower reaches of the Chiwawa River. We observed age- $1+$ steelhead/rainbow mostly in pool, riffle, and multiple-channel habitats. Those that we observed in pools were usually in deeper water than age-0 steelhead/rainbow and Chinook. Like age-0 steelhead/rainbow, age-1+ steelhead/rainbow selected stations in quiet water behind boulders in riffles, but we generally did not find the two age groups together. Age-1+ steelhead/rainbow appeared to use deeper and faster water than did age-0 steelhead/rainbow.

We estimated that steelhead/rainbow larger than 8 inches numbered $14( \pm 71 \%$ of the estimated total) in the Chiwawa River basin in August 2016 (Table 7). During the period 1992-2016, steelhead/rainbow numbers ranged from 8 to 1,869 (Appendix B). Steelhead/rainbow larger than 8 inches were most abundant in the lower Chiwawa River; however, in 1992 and 1993, they were most abundant near campgrounds in Reaches 8,9 , and 10 (these were mostly hatchery rainbow trout planted near the campgrounds). We found very few in tributaries. Most of the steelhead/rainbow larger than 8 inches used deep pools ( $>5$ feet), and occupied stations near the bottom at the upstream end of pools.

## Bull Trout Abundance

We estimated, based on surface area that at least 291 ( $\pm 20 \%$ of the estimated total) juvenile (2-8 in) bull trout lived in reaches of the Chiwawa River basin in August 2016 (Table 8). We found most of these fish in the upper-most reaches of the Chiwawa River and in Rock and Phelps creeks. During 1992-2016, numbers of juvenile bull trout ranged from 79 to 505 (Figure 9; Appendix B). These estimates and those for adult bull trout are incomplete because we did not sample the entire range of bull trout in all tributaries. That is, we did not extend our surveys into the headwaters of the Chiwawa River because there were no juvenile Chinook there. Areas beyond the distribution of juvenile Chinook salmon are known to support bull trout, steelhead/rainbow, and cutthroat trout (USFS 1993). In addition, our estimates of bull trout abundance were based on daytime snorkel surveys, which may underestimate the actual abundance of bull trout. ${ }^{6}$ Several studies (e.g., Goetz 1994; Thurow and Schill 1996; Hillman and Chapman 1996; Bonar et al. 1997) have found bull trout population estimates based on nighttime snorkeling to be in some cases more accurate than daytime snorkeling, especially for juvenile bull trout. Our estimates of adult bull trout numbers may be more accurate than those for juveniles.

In all years, we found most juvenile bull trout in the upstream reaches of the Chiwawa River. In 2016, they occurred primarily in Reaches 9-10 on the Chiwawa River. We found the majority of these fish in multiple channels, pools, and riffles, and few in glides. They consistently occupied stations close to the stream bottom over rubble and small boulder substrate or near woody debris. This is similar to the observation of Pratt (1984) in the upper Flathead River Basin in Montana. She found that juvenile bull trout lay close to instream cover and that they tended to conceal

[^38]themselves. Consequently, she found it difficult to estimate accurately their numbers. Although this implies that we underestimated numbers of juvenile bull trout in the Chiwawa River, the relative distribution of juvenile bull trout is valid if we assume that we saw the same fraction of juveniles in all reaches (i.e., detection probability was the same across survey sites).
We estimated a total of $1,254( \pm 12 \%$ of the estimated total) adult ( $>8$ in) bull trout in reaches of the Chiwawa River basin in August 2016 (Table 9). This was the second highest number of adult bull trout that we recorded during the more than 20-year survey period. During 1992-2016, numbers of adult bull trout ranged from 76 to 2,286 (Figure 9; Appendix B). As with juvenile bull trout, we found most of the adult bull trout upstream from Reach 6; although they were found in all reaches on the Chiwawa River. We found few adult bull trout in tributaries of the Chiwawa River. Adult bull trout primarily used pools and multiple channel habitat, although most of the smaller adults (<10 in) used riffles.

## Abundance of Other Salmonids

In August 2016, we estimated that at least 66 brook trout, an exotic species closely related to the bull trout, occurred in the Chiwawa River, Chikamin Creek, Big Meadow Creek, Minnow Creek, and in the Little Wenatchee River survey areas. In both the Chiwawa and Little Wenatchee rivers, brook trout usually used multiple channels and pools. Few appeared to be bull trout/brook trout hybrids. In Chikamin, Minnow, and Big Meadow creeks, brook trout were most abundant in pools. Brook trout lengths ranged from 2-12 inches.

At least 550 westslope cutthroat trout occurred in the Chiwawa River, Phelps Creek, Rock Creek, and Little Wenatchee River survey areas in August 2016. These fish most often occurred in pools and multiple channel habitats. They ranged in size from 2-22 inches. Juvenile coho salmon were observed in Nason Creek and the Chiwawa River.

We observed both juvenile and adult mountain whitefish in the Chiwawa River, Phelps Creek, Rock Creek, Nason Creek, and the Little Wenatchee River survey areas. In sum, at least 6,031 adult and 1,454 juvenile whitefish lived in these streams in August 2016. We found few whitefish in most tributaries to the Chiwawa River.

## Conclusion

This was the $24^{\text {th }}$ year of a study to monitor trends in juvenile spring Chinook production in the Chiwawa River basin. As shown in Figure 3, numbers of juvenile Chinook salmon in the Chiwawa River basin have fluctuated widely over the 24 -year period. Numbers of juveniles in 2001, 2002, and 2009-2016 were some of the highest recorded, while numbers in the mid-1990s were some of the lowest. Interestingly, the highest spawning escapements (highest redd numbers) resulted in the lowest egg-parr survival rates (Appendix A). This is supported by the fact that the best approximating models clearly demonstrated a density-dependent relationship between seeding levels and juvenile production. Indeed, there was a significant negative relationship between parr per redd and numbers of redds in the Chiwawa River basin. This is an important observation because some of the hypotheses in the revised monitoring and evaluation plan (Hillman et al. 2013) are only valid when the supplemented population is below its carrying capacity.

The best fitting stock-recruitment models indicate that the population capacity of the Chiwawa River basin is between 140,000 to 185,000 spring Chinook parr. This equates to an overall density of about $1,100-1,400$ parr per hectare. These densities can be achieved with about 490 redds. Assuming a female Chinook produces only one redd (Murdoch et al. 2009), a spawning escapement of about 490 females is needed to fill the capacity of the Chiwawa River basin.
The proportion of hatchery-origin spawners ( $\mathrm{pHOS} \mathrm{)} \mathrm{within} \mathrm{the} \mathrm{Chiwawa} \mathrm{River} \mathrm{basin} \mathrm{during} \mathrm{the}$ survey period has ranged from 0 to $100 \%$. Thus, some of the variation in juvenile productivity may be related to pHOS. Although there appeared to be a negative relationship between juvenile productivity (parr/redd) and pHOS, the correlation was not significant (Figure 10). In addition, there was no relationship between juvenile productivity and pHOS after the effects of spawning escapement were removed from the analysis (Figure 10). This suggests that spawning escapement has a larger effect on juvenile productivity than does the presence of hatchery spawners.

The presence of density dependence in the early life stages of spring Chinook is not surprising. Rarely does density dependence appear in numbers of adult spring Chinook or on their spawning grounds. The Chiwawa River basin appears to have plenty of spawning habitat, as indicated by the large numbers of spawners and redds widely distributed throughout the basin during high spawning escapements. However, those large spawning escapements did not translate into large numbers of juveniles or smolts. Thus, density-dependent regulation appears to occur sometime during the early life stages of the fish, likely at the fry stage. It is possible that physical habitat (space) during higher flows when fry are emerging may limit juvenile Chinook production in the basin. Low nutrient levels and its effects on food webs may also be a limiting factor in the basin. If spawning escapements remain relatively high, marine-derived nutrients should increase in the basin, resulting in more food for juvenile Chinook salmon.

[^41]Table 4. Summary of the five productivity models of juvenile (age-0) Chinook salmon in the Chiwawa River basin. Models are shown, including the number of parameters $(K)$, AIC $_{c}$ values, AIC $_{c}$ difference scores $\left(\Delta_{\mathrm{i}}\right)$, the likelihood of the model given the data $\left(£\left(g_{i} \mid x\right)\right.$ ), Akaike weights ( $w_{i}$ ), and adjusted $R^{2}$ values. The sample size ( $n$ ) for all models was 24 . Models describe the relationship between juvenile Chinook numbers (dependent variable) and redd numbers (independent variable).

| Model | $K^{a}$ | $\mathrm{AIC}_{\text {c }}$ | $\Delta_{i}$ | $f\left(g_{i} \mid x\right)$ | $\boldsymbol{w}_{i}$ | Adj $\mathrm{R}^{2}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Beverton-Holt | 3 | -130.391 | 0.000 | 1.000 | 0.661 | 0.841 |
| Smooth Hockey Stick | 3 | -128.692 | 1.698 | 0.428 | 0.283 | 0.829 |
| Gamma ${ }^{\text {b }}$ | 4 | -123.826 | 6.565 | 0.038 | 0.025 | 0.805 |
| Ricker | 3 | -123.279 | 7.112 | 0.029 | 0.019 | 0.786 |
| Cushing | 3 | -122.355 | 8.036 | 0.018 | 0.012 | 0.777 |

${ }^{\text {a }} \boldsymbol{K}$ is the number of structural parameters in the model plus 1 for $\sigma^{2}$.
${ }^{\mathrm{b}}$ The $\gamma$ parameter in the Gamma model was greater than 0 , which means that this model is nearly identical to the Ricker model.

Table 5. Estimated mean densities (fish $/$ hectare and fish $/ \mathrm{m}^{3}$ ), total numbers, $95 \%$ confidence bounds on total numbers, and error of the estimated total number of age-0 $(<4 \mathrm{in})$ steelhead/rainbow in reaches in the Chiwawa River basin, Washington, August 2016.

| Reach | Mean density |  | Surface area (ha) |  |  | Volume ( $\mathrm{m}^{3}$ ) |  |  |

## INTRODUCTION

## Background

## Monitoring and Evaluation

Productivity indicators in the freshwater environment provide data essential to inform evolving salmon and steelhead hatchery programs. In the Wenatchee River subbasin, the Juvenile Monitoring Component of the Monitoring and Evaluation Plan for PUD Hatchery Programs gather data directed at informing these productivity indicators (see Hillman et al. 2013). More specifically, this data directly addresses Objective 2 of the monitoring and evaluation framework:
"Determine if the proportion of hatchery fish on the spawning grounds affects the freshwater productivity of supplemented stocks."

## Objectives

The Washington Department of Fish and Wildlife monitors juvenile salmonids in the Wenatchee River basin with the primary objective of estimating: natural productivity, migration timing, and age with size at migration. This has occurred at the tributary level (Chiwawa River since 1991) and population level (Wenatchee River since 1997). Target species include spring Chinook Salmon Oncorhynchus tshawytscha and summer steelhead O. mykiss in the Chiwawa River, and is expanded to include sockeye Salmon O. nerka and summer Chinook Salmon O. tshawytscha in the mainstem Wenatchee River.

Monitoring has primarily been conducted with rotary smolt traps that capture emigrating salmonids from spring through fall. In an effort to reduce biases in emigrant estimates, and to improve understanding of survival and movement during non-trapping periods (December through February), WDFW began remote sampling spring Chinook Salmon in the Chiwawa Basin in 2012.

## Study Area

## Chiwawa River

The Chiwawa River is a fourth-order river draining a $474-\mathrm{km}^{2}$ basin and has a mean annual discharge of 14.4 cubic meters per second ( $\mathrm{m}^{3} / \mathrm{s}$ ); contributing about $15 \%$ of the mean annual discharge of the Wenatchee River. The Chiwawa basin is dominated by the snow melt cycle with peak discharge occurring May through July with occasional fall freshets (Figure 1). The Chiwawa River originates in the North Cascades and flows southeast for 60 km before joining the Wenatchee River. This confluence with the Wenatchee River is approximately 9 km downstream of Lake Wenatchee and 76 km upstream of the Columbia River (Figure 2). The Chiwawa River basin is relatively natural, with $96 \%$ managed as part of the Wenatchee National Forest and the upper $32 \%$ designated wilderness.

Precipitation in the basin varies between 76 cm near the confluence and 356 cm at the peaks, while elevations range from 573 to $2,768 \mathrm{~m}$. The river is dynamic with generally shallow pool
riffle segments as it meanders through a U-shaped valley formed by ancient glaciers in the region. Gradients remain well under $1 \%$ for the majority of the river.

Figure 1. Discharge of the Chiwawa River at Plain, USGS gauge \# 12456500. Black line represents 2016 discharge and grey line represents mean discharge from 1990-2015.

Figure 2. Wenatchee River basin (with rotary smolt trap locations).

## Wenatchee River

The Wenatchee River is a fourth-order river draining a $3,437-\mathrm{km}^{2}$ basin and has a mean annual discharge of $91.4 \mathrm{~m}^{3} / \mathrm{s}$. The hydrograph is dominated by the snow melt cycle with peak discharge occurring May through July with occasional fall freshets (Figure 3). The mainstem originates at the outlet of Lake Wenatchee and flows southeast 84.5 km before joining the Columbia River, 753 km upstream of the Pacific Ocean (Figure 2). While most of the lowlands ( $17 \%$ ) are private, the majority ( $83 \%$ ) of basin is public land.

Precipitation in the basin varies from 22 cm near the Columbia River confluence to 381 cm at the crest of the Cascade Mountains with elevations ranging from 237 to $2,768 \mathrm{~m}$. The Wenatchee River has a relatively low gradient except from rkm 40-64 where the river flows through a bedrock canyon (Tumwater Canyon) and has a gradient of approximately 9.8 meters per kilometer.

Figure 3. Discharge of the Wenatchee River at Monitor, USGS gauge \# 12462500. Black line represents 2016 discharge and grey line represents mean discharge from 1990-2015.

## METHODS

## Rotary Smolt Traps

## Trap Operations

The Chiwawa River trap consists of a single 2.4 m cone and has been operating since 1991 at its current location, 0.6 km upstream from the confluence with the Wenatchee River. Trap operations usually begin in late February and continue until ice suspends operations in late fall. The Lower Wenatchee trap consists of two 2.4 m cones and has been operating in its current location (rkm 12.5) since 2013. Trap operations usually begin in late January and continue until fall, when river conditions force its removal.

Operational procedures and techniques follow the standardized basin-wide monitoring plan developed by the Upper Columbia Regional Technical Team for the Upper Columbia Salmon Recovery Board (UCSRB; Hillman 2004), which was adapted from Murdoch and Petersen (2000). The traps remain in operation 24 hours a day unless environmental condition (high/low flow, extreme temperature, and high debris), hatchery releases, mechanical failure or human recreational activities halt operations. During periods of high recreational activities in the spring and summer the Lower Wenatchee trap is pulled during daylight hours to minimize human danger.

## Fish Sampling

At a minimum of once a day, all fish collected at the traps were identified to genus or species, enumerated, weighed, and fork length (FL) measured. All salmonids were classified as hatchery, wild, or unknown and visually classified as fry, parr, transitional, or smolt. All hatchery salmonids in the basin are marked (adipose fin-clip, coded-wire tags, or Passive Integrated Transponder (PIT) with the exception of coho. Based on length subsamples of known hatchery coho at Leavenworth Fish Hatchery, all coho collected at the Lower Wenatchee rotary smolt trap were considered wild if $<80 \mathrm{~mm}$ FL or unknown origin if $\geq 80 \mathrm{~mm}$ FL. All coho collected in the Chiwawa River were considered wild. Target species ( $\geq 65 \mathrm{~mm} \mathrm{FL}$ ) were tagged using 12.5 mm FDX PIT tags and all PIT tagging information was uploaded to a reginal PIT tag database (PTAGIS) maintained by the Pacific States Marine Fisheries Commission.

A combination of length, time of year, and trap location was used to determine race (spring or summer) of captured juvenile Chinook Salmon. All Chinook Salmon captured in the Chiwawa River trap were considered spring Chinook, regardless of size since summer Chinook Salmon spawning has not been documented upstream of the trap. All yearling (age-1) Chinook captured at the Lower Wenatchee River trap during the spring migration period were considered spring Chinook Salmon because spring Chinook Salmon are yearling migrants and summer Chinook Salmon are typically subyearling migrants. All subyearling fry and parr (age-0) Chinook captured at the Lower Wenatchee River trap during spring were considered summer Chinook Salmon.

## Mark-Recapture Trials

Groups of marked juveniles were released during a range of stream discharges in order to determine trapping efficiencies under the varied flow regime. Natural origin fish were marked with a PIT tag if $\geq 65 \mathrm{~mm}$ FL or stained with Bismarck Brown dye if $<65 \mathrm{~mm}$ FL and hatchery origin fish were marked using a caudal fin clip. All marked fish were released evenly upstream on both sides of the river between 1800 hours and 2000 hours. Marked fish from the Lower Wenatchee River trap were transported and released 14.5 km upstream of the trap site while fish from the Chiwawa River trap were released 2.6 km upstream. Each trial was conducted over a four-day ( 96 hour) period to allow time for passage or capture. Target mark group sizes were based on historical data, location and species, ranging from 100 to over 500 individual fish. See appendix D for mark-recapture trails.

## Emigrant Estimates

All emigration estimates were calculated using estimated daily trap efficiency derived from the regression formula using trap efficiency (dependent variable) and discharge (independent variable). Trap efficiency models used a modified Bailey estimator (recaptures +1 ) in the calculation of efficiency as a method of bias correction. If a significant relationship ( $R^{2}>0.5$ and $P<0.05$ ) could not be found a pooled trap efficiency estimate was used. Estimates of emigrating spring Chinook were calculated with and without fry ( $<50 \mathrm{~mm}$ FL) due to the uncertainty that these fish were actively migrating to the ocean (UCRTT, 2001). See appendices $A$ and $B$ for detailed equations and information on how the point estimate, variance, and standard error were calculated.

During minor breaks in operation (less than seven days), the number of individual fish collected was estimated. This estimate was calculated using the mean number of fish captured two days prior and two days after the break in operation. For major breaks in operations (greater than seven days), an estimate based on historical run timing was developed. This estimate of daily capture was incorporated into the overall emigration estimate.

## Egg-to-emigrant Survival

The estimated total egg deposition (d) was calculated by multiplying the mean fecundity (f) of the brood spawners by the total number of redds (r) found during surveys (Hillman et al. 2015). Egg-to-emigrant survival (s) was calculated by dividing total emigrants (e) by estimated egg deposition (d).

## Backpack Electrofishing

## Sampling Procedure

From 2012 to present, WDFW has had a goal of PIT tagging 3,000 juvenile spring Chinook Salmon each year. In order to representatively tag the population throughout all reaches, the number of fish tagged in each reach was based on the reach specific abundance encountered during snorkeling surveys in late summer. See Appendix C for further explanation.

## Detections and Calculations

Detections occur at PIT tag interrogation sites in and out of the basin as well as rotary smolt traps downstream of the sampling reaches. Calculations of non-trapping emigrant estimates are based on a flow-detection efficiency regression developed using mark-groups previously released to test smolt trap efficiencies. The total number of tagged fish ( $t$ ) divided by the estimated total parr abundance (p), as based off of standard snorkeling techniques (Hillman et al. 2013), resulted in an overall tag rate ( $\mathrm{t}_{\mathrm{i}}$ ). See Appendix C for further explanation.

## RESULTS

## Rotary Smolt Traps - Chiwawa

Trap Operation
The Chiwawa trap operated between 2 March and 21 November 2016. During that time the trap was inoperable for 72 days as a result of low or high discharge, debris, hatchery fish releases, and mechanical issues. Forty seven of those days came during the fall when there was not enough discharge to operate the trap. Throughout the year the trap was operated in a single upper position.

## Fish Sampling

A total of 27,172 individual fish were collected, with wild spring Chinook Salmon and steelhead comprising $71 \%$ and $6 \%$ of the total catch, respectively. Additionally, 2,525 hatchery spring Chinook, 1,518 hatchery steelhead, and 3 wild coho were collected. Throughout the sampling period 11,396 PIT tag were deployed into wild spring Chinook and steelhead (10,083 and 1,313 respectively). Spring Chinook mortality for the season totaled 4 yearling, 74 subyearling parr, and 15 fry ( $0.1 \%, 0.6 \%$, and $0.4 \%$, respectively). Mortality of steelhead throughout the season totaled 10 ( $0.6 \%$ ). The mean fork length (SD) of captured yearling and subyearling spring Chinook Salmon (fry excluded) was 91 (8.5) mm and 71 (12.78) mm, respectively (Table 1).

Table 1. Mean fork length (mm) and weight (g) of spring Chinook Salmon captured in the Chiwawa rotary smolt trap during 2016.

## Yearling Spring Chinook (Brood Year 2014)

Wild yearling spring Chinook Salmon were primarily captured between 2 March and 31 May (Figure. 4). A total of 2,807 yearling Chinook Salmon were captured and an estimated 3,414 would have been captured if the trap had operated without interruption. Six mark/recapture efficiency trials using PIT tags were conducted producing a mean trap efficiency of $9.4 \%$. In 2016, mark/recapture trials were conducted at all desired discharge levels and a statistically
significant flow-efficiency regression model was obtained ( $R^{2}=0.84, \mathrm{P}<0.028$ ). The estimated number ( $95 \%$ C.I.) of yearling spring Chinook Salmon that emigrated from the Chiwawa River in 2015 was $37,170( \pm 6,524)$. Smolt survival (SE) to McNary of those tagged fish was $43 \%$ (5\%) using the Cormack-Jolly-Seber estimator.

Figure 4. Daily catch of yearling spring Chinook Salmon at the Chiwawa rotary smolt trap. Blue line indicates river discharge and red horizontal line indicates non-trapping period.

## Subyearling Spring Chinook (Brood Year 2015)

Wild subyearling spring Chinook Salmon were captured throughout the sampling period, with peak catches of parr in August, October, and November and fry occurring in March and April (Figures 5 and 6, respectively). A total of 12,429 subyearling parr and 3,835 fry were captured with an estimated 13,319 subyearling parr and 4,063 fry had the trap operated without interruption. Twelve mark/recapture efficiency trials were conducted (eight PIT tagged and four Bismarck Brown groups) with a mean trap efficiency of $19.1 \%$. These 12 trials were used to develop a significant regression model for the trap ( $\mathrm{R}^{2}=0.64, \mathrm{P}<0.002$ ). In 2016, the estimated number of subyearling spring Chinook Salmon emigrating from the Chiwawa River during the sampling period was $80,543( \pm 27,967)$ if you do not include fry or $145,971( \pm 48,393)$ if fry are included.

Figure 5. Daily catch of wild spring Chinook subyearling parr at the Chiwawa rotary smolt trap. Blue line indicates river discharge and red horizontal line indicates non-trapping period.

Figure 6. Daily catch of wild spring Chinook fry at the Chiwawa rotary smolt trap. Blue line indicates river discharge and red horizontal line indicates non-trapping period.

## Summer Steelhead

During the trapping period, 195 steelhead transitional/smolts and 1,522 steelhead/rainbow parr and fry were captured. While collections occurred in moderate numbers throughout the year, peak collections occurred during September and October (Figure 7). The mean fork length (SD) of steelhead parr and transitional/smolts captured was 83.6 (23.1) and 146.7 (33.4) mm, respectively (Table 2).

Figure 7. Daily catch of all wild steelhead at the Chiwawa rotary smolt trap. Blue line indicates river discharge and red horizontal line indicates non-trapping period.

| Weight | 37.3 | 23.7 | 194 |  | 7.8 | 9.4 | 1,393 |

## Egg-to-emigrant Survival

For BY 2014, 485 redds were counted in the Chiwawa River Basin with an estimated 1,961,825 eggs being deposited. A total of 114,680 emigrants were estimated resulting in an egg-toemigrant survival of $5.8 \%$ (Table 3). This is up from a five year moving average of $3.8 \%$.

${ }^{\text {a }}$ calculated with Bailey model

## Non-target Taxa

Bull trout (Salvelinus confluentus) also comprised a large proportion of incidental species captured. During the trapping period 118 bull trout ( $15 \geq 300 \mathrm{~mm} \mathrm{FL}$ and $103<300 \mathrm{~mm} \mathrm{FL}$ ) were captured. Additionally, 43 westslope cutthroat trout (O. clarki lewisi), and three Eastern brook trout (S. fontinalis) were collected. In all, 109 bull trout and 41 westslope cutthroat trout were released with PIT tags. Monthly and annual totals of all fish captured are presented in Appendix E and Appendix F, respectively.

## Rotary Smolt Traps - Lower Wenatchee

## Trap Operation

The Lower Wenatchee trap operated from 29 January through 26 July 2016. During this time the trap was inoperable for a total of 23 days due to high/low flows, high temperatures, heavy debris, major hatchery releases, and mechanical issues. Extreme river temperatures and low flows resulted in trapping operations being suspended for the season on 26 July. Throughout the season, the trap cones were operated in a single lower position.

## Fish Sampling

A total of 43,685 individual fish were collected, with wild summer Chinook Salmon comprising $89 \%$ of the total catch. Additionally, 610 wild yearling spring Chinook Salmon, 7,701 hatchery yearling Chinook Salmon, 1,346 wild sockeye, 417 wild steelhead, and 259 hatchery steelhead were captured. Throughout the sampling period 567, 1,065, and 131 PIT tag were deployed into wild yearling spring Chinook, sockeye, and steelhead, respectively. Mortality for the season totaled 2 yearling spring Chinook, 184 subyearling summer Chinook, 63 sockeye, and 6 steelhead ( $0.3 \%, 0.7 \%, 4.7 \%$, and $1.4 \%$, respectively).

## Wild Yearling Spring Chinook (Brood Year 2014)

Wild yearling spring Chinook Salmon were primarily captured in February and March (Figure 8). Throughout the trapping period 610 spring Chinook were collected and an estimated 708 would have been collected had the trap operated without interruption. A combination of 2013, 2014, and 2015 trials were used to develop a significant relationship between discharge and trap efficiency ( $R^{2}=0.62, P=0.02$ ). This model was used to calculate an emigrant estimate of 36,752 $( \pm 5,330)$. The mean fork length (SD) of captured yearling Chinook was 94 (9.4) mm (Table 4).

Figure 8. Daily capture of wild yearling Chinook Salmon at the Lower Wenatchee rotary smolt trap. Blue line indicates river discharge and red horizontal line indicates non-trapping period.

Table 4. Mean fork length (mm) and weight (g) for wild yearling spring Chinook Salmon sampled at the Lower Wenatchee rotary trap during 2016.

|  | Mean | SD | N |
| :--- | :---: | :---: | :---: |
| Fork length | 94 | 9.4 | 600 |
| Weight | 9.0 | 2.9 | 598 |

Wild Subyearling Summer Chinook (Brood Year 2015)

Wild subyearling summer Chinook dominated the catch (63\%) with 27,407 fish being processed, most being collected in April and May (Figure 9). An estimated 35,815 would have been captured had the trap operated without interruption. Over the season, four mark/recapture efficiency trials were carried out using Bismarck Brown dye. When combined with trials from 2014 and 2015 a significant discharge efficiency relationship was developed ( $R^{2}=0.56, P<$ 0.001 ) and an emigrant estimate ( $95 \%$ C.I.) of $4,023,310( \pm 676,633)$ was calculated. The mean fork length (SD) for captured subyearling parr and fry summer Chinook was 64 (10.1) and 40 (3.7), respectively (Table 5). Over the sampling period 18 PIT tags were deployed in summer Chinook.

Figure 9. Daily capture of wild summer Chinook Salmon at the Lower Wenatchee rotary smolt trap. Blue line indicates river discharge and red horizontal line indicates non-trapping period.

Table 5. Mean fork length ( mm ) and weight ( g ) of subyearling summer Chinook Salmon sampled at the Lower Wenatchee rotary smolt trap.

|  | Transition / Smolt |  |  | Parr |  | Fry |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Mean | SD | N | Mean | SD | N | Mean | SD | N |
| Fork length | 82.8 | 7.3 | 216 | 64.1 | 10.1 | 2,799 | 40.9 | 3.7 | 3,143 |
| Weight | 6.4 | 1.8 | 216 | 3.1 | 1.6 | 2,778 | 0.6 | 0.3 | 3,005 |

Wild Sockeye
A total of 1,346 juvenile sockeye were collected in the 2016 season and an estimated 1,916 had the trap operated without interruption. Almost all of these fish (84\%) were collected in April (Figure 10). No mark/recapture efficiency trials were carried out due to mechanical issues during the peak of the run. Mark/recapture efficiency trials from the 2013, 2014, and 2015 seasons created a significant discharge efficiency model $\left(R^{2}=0.52, P<0.043\right)$. This model
produced a 2016 emigrant population estimate ( $95 \%$ C.I.) for juvenile sockeye at 208,250 $( \pm 29,447)$. Smolt survival (SE) to McNary of those tagged fish was $26 \%(5 \%)$ using the Cormack-Jolly-Seber estimator. In 2016, while most were Age 1+ (78\%), we saw a large jump in Age 2+ (22\%) when compared to 2014 and 2013 (Table 6). Mean fork length (SD) for captured sockeye was 81 (12.1) mm (Table 7).

Figure 10. Daily capture of wild sockeye Salmon at the Lower Wenatchee rotary smolt trap. Blue line indicates river discharge and red horizontal line indicates non-trapping period.

Table 6. Age structure and estimated number of wild sockeye smolts that emigrated from Lake Wenatchee in 2013-2015.

## Wild Summer Steelhead

Capture of wild steelhead at the Lower Wenatchee site for all life stages was low, totaling 417 fry, parr, and smolts combined and an estimated 505 collected had the trap operated without
interruption. Peak catches of steelhead occurred in July (Figure 11). One mark/recapture trial was conducted using hatchery steelhead transitional/smolts in 2016. When combined with two trials using hatchery steelhead transitional/smolts 2014 a pooled efficiency of 0.028 was used to estimate ( $95 \%$ C.I.) the emigrant population (no fry) at $10,135( \pm 102,145$ ) parr and smolt emigrant steelhead. If you include fry, the emigrant population was estimated at 18,400 ( $\pm$ $185,447)$. However, due to the low number of trials, small sample sizes, use of hatchery transitional/smolts surrogates and the relationship not being significant, caution should be used in the interpretation and use of the estimate. Mean length (SE) of transitional/smolts and parr was 159 (29.6) and 83 (24.0) mm, respectively (Table 8).

Figure 11. Daily capture of wild steelhead at the Lower Wenatchee rotary smolt trap. Blue line indicates river discharge and red horizontal line indicates non-trapping period.

Table 8. Mean fork length (mm) and weight (g) of wild steelhead sampled at the Lower Wenatchee rotary smolt trap.

|  | Transitional/Smolt |  |  | Parr |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Mean | SD | N | Mean | SD | N |
| Fork length | 159.4 | 29.6 | 66 | 83.1 | 24.0 | 102 |
| Weight | 45.7 | 27.4 | 66 | 7.7 | 6.6 | 99 |

## Survival

For BY 2014, 885 spring Chinook Salmon redds were surveyed in the Wenatchee Basin producing an estimated $3,894,000$ eggs. An estimate of 36,752 emigrants results in an estimated egg-to-emigrant survival of $0.94 \%$. This is down from the last three year average of 1.45\% (Table 9).

Table 9. Estimated egg deposition and egg-to-smolt survival rates for Wenatchee Basin spring

Chinook Salmon.

| Brood <br> Year | Number <br> of redds | Estimated egg <br> deposition | Total <br> emigrants | Egg-to-emigrant <br> survival (\%) |
| :---: | :---: | :---: | :---: | :---: |
|  | 350 | $1,758,050$ | 76,643 | 4.36 |
| 2001 | 1,876 | $8,674,624$ | 243,516 | 2.81 |
| 2002 | 1,139 | $5,300,906$ | 165,116 | 3.11 |
| 2003 | 323 | $1,887,612$ | 70,738 | 3.75 |
| 2004 | 555 | $2,663,445$ | 55,619 | 2.09 |
| 2005 | 829 | $3,587,083$ | 302,116 | 8.42 |
| 2006 | 588 | $2,542,512$ | 85,558 | 3.37 |
| 2007 | 466 | $2,069,506$ | 60,219 | 2.91 |
| 2008 | 1,411 | $6,479,312$ | 82,137 | 1.27 |
| 2009 | -- | -- | -- | -- |
| 2010 | -- | -- | -- | -- |
| 2011 | 872 | $3,823,720$ | 89,917 | 2.35 |
| 2012 | 1,704 | $7,195,992$ | 67,973 | 0.94 |
| 2013 | 1,159 | $5,512,204$ | 58,595 | 1.06 |
| 2014 | 885 | $3,894,000$ | 36,752 | 0.94 |

For BY 2015, 2,725 summer Chinook Salmon redds were surveyed in the Wenatchee Basin, $95.8 \%$ being upstream of the Lower Wenatchee smolt trap. After extrapolating by the proportion of redds above the trap a total emigrant population of $4,023,310$ was estimated resulting in an egg-to-emigrant survival of $36.55 \%$. This is down from the last three year average of $83.54 \%$ (Table 10).

Table 10. Estimated egg deposition and egg-to-emigrant survival rates for Wenatchee Basin summer Chinook Salmon.

## Non-target Taxa

No westslope cutthroat trout or bull trout where sampled at the Lower Wenatchee Trap. No PIT tags were applied to non-target taxa. Monthly and annual totals of all fish captured are presented in Appendix G and Appendix H, respectively.

## Backpack Electrofishing

## Fish Sampling

Between 19 October and 12 November 2015, WDFW personnel sampled the Chiwawa River for a total of 36,782 seconds. During this sampling, a total of 1,103 subyearling Chinook were collected of which 1,054 received a PIT tag. The greatest concentration of juvenile Chinook occurred between rkm 31 and 45 which had a mean sample rate of one Chinook collected for every 24 seconds of sampling. Over the sample period 20 Chinook died resulting in a mortality rate of $1.8 \%$. Additionally, 63 juvenile bull trout were collected and 43 received a PIT tag. Highest catch rates for bull trout were around rkm 47. No mortality was observed for bull trout.

## Detections and Calculations

Between the non-trapping season of 25 November 2015 through 1 March 2016, a total of three detections of remotely tagged Chinook were recorded at the lower Chiwawa antenna array. During the 2015 fall ( 19 October through 24 November) and 2016 spring trapping season ( 2 March and 30 June), the Chiwawa rotary smolt trap collected 29 and 26 remotely tagged Chinook, respectively. Due to relatively low sample size and poor detection rates at the Chiwawa antenna no emigrant estimate for the non-trapping period was calculated for the BY 2014.

## DISCUSSION

## Chiwawa River Rotary Smolt Trap

Over the last five years the Chiwawa River smolt trap has had an average installation date of 1 March. With a relatively normal winter the smolt trap was installed on 2 March. However the spring proved to be one of the warmest leading to a record high discharge for much of the spring and very low flows in the fall. In the spring the trap was pulled due to high flow/debris for 22 days and in the fall it was pulled for 47 days due to low flow.

Floods in the fall of 2015 - spring 2016 also caused the substrate to sift and altered the range of flows the Chiwawa River rotary smolt trap is considered operable. New discharge limits are estimated to be between 4.5 and $55.2 \mathrm{~m}^{3} / \mathrm{s}$. For the 2017 field season we will adjust our methodology to allow for sampling during low discharge levels by replacing our 2.4 m smolt trap with a 1.5 m smolt trap as needed.

Due to the assumed change in trap efficiencies associated with a single cone positions and altered substrate new trap efficiency models were developed for subyearling and yearling Chinook. However, a continued reliance upon historic mark/recapture trials for steelhead had to be used. This model will continue to be improved and updated as conditions allow. Historically, emigrant estimates were calculated using the Peterson estimator of abundance (Seber 1982), however more accurate estimates currently utilize a modified Bailey estimator (Murdoch et al. 2012).

The total production estimate for brood year 2014 was 114,680 and comprises estimates of subyearling emigrants in 2015 and yearling emigrants in 2016. Unfortunately, high flows, low antenna detections, and concerns related to spawning bull trout resulted in an abbreviated sampling window and prevented the completion of 2015 remote tagging efforts. This resulted in no estimate being calculated for the 2015 non-trapping season and a known underestimate of the total brood year production. Protocols and field sampling will be continually adapted to fit within environmental and permit constraints and estimates will be improved upon when possible.

Due to the large fall break in trapping historic run timing was used to extrapolate what the catch would have been had the trap been able to operate without interruption. It was estimated $6.5 \%$ of subyearling Chinook emigrated during this fall break in trapping so our subyearling Chinook emigrant estimate was adjusted accordingly.

The 2016 field season represented the first year the smolt trap operated with a single cone position. This allowed for a single model to be developed for each life stage and species regardless of when it emigrated, thus removing bias and improving our estimates for subyearling and yearling Chinook. In 2017 we will continue to develop and modify our mark/recapture models paying particular attention to improving our steelhead model.

## Lower Wenatchee River Rotary Smolt Trap

Historically, the smolt trap on the mainstem Wenatchee River has moved location numerous
times due to poor trap efficiencies of target species and environmental factors causing abbreviated trapping seasons. At the lower Wenatchee site, the smolt trap has been able to operate into September in 2013 and October in 2014. This marks a relatively large increase in operational length over the old site (located 2.5 km downstream) which had an average trap removal date of 14 August. However, since 2014 river discharge and water temperatures have hampered the trapping season for the Lower Wenatchee trap. At this site, the trap is considered operable between discharges of 36.8 and $283.2 \mathrm{~m}^{3} / \mathrm{s}$. In 2016, record high spring discharge resulted in the trap being pulled for 19 days, mostly in April and May. Complicating things further, river temperatures exceeded starting $20^{\circ} \mathrm{C}$ starting 27 July and trapping operations were again suspended. River temperatures remained elevated and low flow persisted through summer and on 19 August the decision was made to remove the smolt trap. Additionally, mechanical issues hindered catch totals and subsequent emigrant estimates. This was particularly evident when mechanical issues led to only one cone being operable for five days during the peak sockeye emigration. This caused a known underestimate of total catch and emigrant estimate. Overall however, river discharge and temperature continue to be the main issues that impact our trapping season. Adaptive management will be use to ensure maximum efficiency and number of days trapping.

Significant discharge efficiency models were obtained for three of the four target species at the Lower Wenatchee trap during the 2016 trapping season (wild spring and summer Chinook Salmon and sockeye Salmon). Collections of wild steelhead continue to be inadequate for conducting mark-recapture trials. In 2017, hatchery steelhead from the Chiwawa acclimation site will be used in mark/recapture trials in an effort to improve emigrant estimates of this target species. This approach requires the assumption that hatchery fish behave in a similar manner to wild fish, an assumption we will test over time as possible. While the new trap location has allowed for greater operational flexibility, it does require the development of new flow-efficiency models. While this can be accomplished relatively quickly with species that are relatively abundant (e.g., summer Chinook and sockeye), it may take several years for those in low abundance (e.g., steelhead). Fortunately, given similar operation parameters across time, we will be able to reexamine past abundance estimates when those models are fully developed.

## Backpack Electrofishing

Remote sampling in the Chiwawa Basin started in 2012. Some success occurred early with PIT tag targets being met, however, there have been substantial obstacles since 2013. Permit restrictions limit field operations until bull trout spawning has concluded; which typically occurs early October. At this time, weather becomes increasingly unfavorable and elevated discharge along with cold air and water temperatures hinder sampling efforts. Since 2014, early high water events hindered sampling efforts and limited not only the area that was sampled, but also the number of fish that were processed. Future investigations will look into alternative sampling techniques and the allocation of personnel to maximize sampling efforts in the basin.

## APPENDICES

## Appendix A. Peterson Population and Variance Equations.

Trap efficiency was calculated using the following formula:

$$
\text { Trap efficiency }=E_{i}=R / M i,
$$

Where $E_{i}$ is the trap efficiency during time period $i ; M_{i}$ is the number of marked fish released during time period $i$; and $R_{i}$ is the number of marked fish recaptured during time period $i$. The number of fish captured was expanded by the estimated daily trap efficiency ( $e$ ) to estimate the daily number of fish migrating past the trap using the following formula:

$$
\text { Estimated daily migration }=\hat{N}_{i}=C_{i} / \hat{e}_{i}
$$

where $N_{i}$ is the estimated number of fish passing the trap during time period $i ; C_{i}$ is the number of unmarked fish captured during time period $i$; and $e_{i}$ is the estimated trap efficiency for time period $i$ based on the regression equation.

The variance for the total daily number of fish migrating past the trap was calculated using the following formulas:

where $X_{i}$ is the discharge for time period $i$, and $n$ is the sample size. If a relationship between discharge and trap efficiency was not present (i.e., $P<0.05$; $r^{2} 0.5$ ), a pooled trap efficiency was used to estimate daily emigration:

$$
\text { Pooled trap efficiency }=e_{p}=\sum R / \sum M
$$

The daily emigration estimate was calculated using the formula:

$$
\text { Daily emigration estimate }=\hat{N}_{i}=C_{i} / e_{p}
$$

The variance for daily emigration estimates using the pooled trap efficiency was calculated using the formula:

Variance for daily emigration estimate $=\operatorname{var}\left[\hat{N}_{i}\right]=\hat{N}_{i}^{2} \frac{e_{p}\left(1-e_{p}\right) / \sum M}{e_{p}^{2}}$ The total emigration estimate and confidence interval was calculated using the following formulas:

$$
\begin{gathered}
\text { Total emigration estimate }=\sum \hat{N}_{i} \\
95 \% \text { confidence interval }=1.96 \times \sqrt{\sum \operatorname{var}}\left[\hat{N}_{i}\right]
\end{gathered}
$$

## Appendix B. Bailey Population and Variance Equations.

Trap efficiency was calculated using the following formula:

$$
\begin{gathered}
\text { Trap efficiency }=E_{i}=R+1 / \mathrm{Mi}, \\
\text { Estimated daily emigration }=\hat{N}_{i}=\frac{C_{i}+1}{\hat{e}_{i}}
\end{gathered}
$$

The variance of the total population abundance was calculated as follows:

$$
\operatorname{Var}\left(\sum_{i=1}^{n} \hat{N}_{i}\right)=\underbrace{\sum_{i} \operatorname{Var}\left(\frac{\left(C_{i}+1\right)}{\hat{e}_{i}}\right)}_{\text {Part } A}+\underbrace{\sum_{i} \sum_{j} \operatorname{Cov}\left(\frac{\left(C_{i}+1\right)}{\hat{e}_{i}}, \frac{\left(C_{j}+1\right)}{\hat{e}_{j}}\right)}_{\text {Part B }}
$$

Part A is the variance of the daily estimates where $C_{i}$ is the number of fish caught in period $i, \mathrm{e}_{\mathrm{i}}$ is the estimated trap efficiency for period $i$, and Cov is the between day covariance for days that the same linear model is used (part B). For a more details and derivation of Peterson and Bailey estimation methods see Murdoch et al. (2012).

## Appendix C. Emigration during non-trapping periods.

A flow-efficiency regression model was developed for the lower Chiwawa River PIT tag interrogation site ( CHL ) using the same mark/recapture trials used for estimating efficiency at the smolt trap. This CHL model was used to calculate emigration outside of the trapping period by incorporating the tag rate into the Bailey estimator.

$$
\begin{aligned}
& \text { Estimated daily emigration }=\left(\hat{N}_{i}=\frac{C_{i}+1}{\hat{e}_{i}}\right) / t_{i} \\
& \text { Where } \mathrm{t}_{\mathrm{i}} \text { is equal to the tag rate }=t_{i}=\frac{t}{p}
\end{aligned}
$$

Appendix D: Mark-recapture groups used to developing emigrant estimates. YCW = Yearling spring Chinook wild, YCH = Yearling spring Chinook hatchery, SKW = Sockeye wild, SUCH = summer Chinook wild, SBC = subyearling Chinook wild.

## Appendix D

Wenatchee Steelhead Spawning Escapement Estimates, 2016

# Estimates of Wenatchee Steelhead Spawners in 2016 

Kevin See

January 06, 2017

## Introduction

Redd counts are an established method to provide an index of adult spawners (Gallagher et al. 2007). In the Wenatchee and Methow subbasins, index reaches are surveyed weekly during the steelhead spawning season (Mar 07, 2016 - May 26, 2016) and non-index reaches are surveyed once during the peak spawning period. The goal of this work is to:

- Predict observer net error, based on a model developed with data from steelhead redd surveys in the Methow, similar to that described in Murdoch et al. (2014).
- Use estimates of observer net error rates and the mean survey interval to estimate the number of redds in each index reach, using a Gaussian area under the curve (GAUC) technique described in Millar et al. (2012).
- Estimate the total number of redds in the non-index reaches by adjusting the observed counts with the estimated net error.
- Convert these estimates of redds in the mainstem areas (surveyed for redds) into estimates of spawners.
- Use PIT-tag based estimates of escapement for all tributaries in the Wenatchee, and combine those estimates with the redd-based estimates of spawners in the mainstem areas to estimate the total number of spawners in the Wenatchee.

## Methods

## Mainstem areas

The model for observer net error (observed redd counts / true number of redds) is a model averaging of the 2 best models that were fit to 43 data points in the Methow. Both models contained covariates of observed redd density (redds / m) and mean thalweg CV as a proxy for channel complexity. One model also contained discharge while the other also contained total redd survey experience as an additional covariate. Predictions were made using model averaged coefficients (based on AICc model weights) and the 2016 steelhead data. From these survey specific estimates of net error, a mean and standard error of net error was calculated for each reach. The standard deviation was calculated by taking the square root of the sum of the squared standard errors for all predictions within a reach.

Estimates of total redds were made for each index reach using the GAUC model described in Millar et al. (2012). The GAUC model was developed with spawner counts in mind. As it is usually infeasible to mark every individual spawner, only total spawner counts can be
used, and an estimate of average stream life must be utilized to translate total spawner days to total unique spawners. However, in adapting this for redd surveys, two modification could be used. The first would fit GAUC models to data showing all visible redds at each survey, and use an estimate of redd life as the equivalent of spawner stream life. However, because conditions can lead to many redds not disappearing before the end of the survey season, the estimates of redd life can be biased low. The second method relies on the fact that individual redds can be marked, and therefore the GAUC model can be fit to new redds only. The equivalent of stream life thus became the mean and standard deviation of the survey interval. We utilized the second method for this analysis.

For non-index reaches, which were surveyed only once during peak spawning, the estimate of total redds was calculated by dividing the observed redds by the estimate of net error associated with that survey. This assumes that no redds were washed out before the nonindex survey, and that no new redds appeared after that survey. As the number of redds observed in the non-index reaches ranged from 0 to 3 , any violoation of this assumption should not affect the overall estimates very much. Based on the peak spawning time for the associated index reaches, the surveys in the non-index reaches were conducted either at peak spawning, or within 10 days after peak spawning (Figure 2\}).

To convert estimates of total redds into estimates of natural and hatchery spawners, total redds were multiplied by a fish per redd ( FpR ) estimate and then by the proportion of hatchery or wild fish. The fish per redd estimate was based on PIT tags from the branching patch-occupany model (see below) observed to move into the lower or upper Wenatchee (below or above Tumwater dam). FpR was calculated as the ratio of male to female fish, plus 1. This was 1.65 above Tumwater dam, and 1.61 below Tumwater. Reaches W1 - W7 are below Tumwater, while reaches W8 - W10 are above Tumwater. Similarly, the proportion of hatchery and natural origin fish was calculated from the same group of PIT tags for areas above and below Tumwater. The proportion of hatchery origin fish was 0.45 above Tumwater dam, and 0.35 below Tumwater (Table 2).

## Tributary areas

Esimates of escapement to various tributaries in the Wenatchee were made using a branching patch-occupancy model (Waterhouse, L. et al., in prep) based on PIT tag observations of fish tagged at Priest Rapids dam. All fish that escaped to the various tributaries were assumed to be spawners (i.e. pre-spawn mortality only occurs in the mainstem).

## Total spawners

When summing spawner estimates from index reaches to obtain estimates of total spawners in the Wenatchee, an attempt was made to incorporate the fact that the reaches within a stream are not independent. Estimates of correlation between the reaches within a stream were made based on weekly observed redds. Because correlations are often quite high between reaches, this is a better alternative than to naively assume the standard errors between reaches are independent of one another. These estimates of correlation were combined with estimates of standard error for each index reach to calculate a
covariance matrix for the Wenatchee index reaches (W6, W8, W9, W10), which was used when summing estimates of spawners to estimate the total standard error. Failure to incorporate the correlations between reaches would result in an underestimate of standard error at the population scale. Non-index reaches were only surveyed once, so it is impossible to estimate a correlation coefficient between non-index reaches and index reaches. Therefore, they were assumed to be independent from the index reachs when summing the estimates of spawners. Because the estimates of tributary spawners were made separately (see above), they were also treated as independent when summing spawner estimates. The uncertainty in each step was carried through the entire analysis via the delta method (Casella and Berger 2002).

## Results

## Redd estimates

It should be noted that the GAUC parameters from index reaches were not used to estimate total redds in the associated non-index reaches. Figure 4 does illustrate that the non-index reach surveys were conducted close to the period of peak spawning (as determined by the associated index reaches), thus helping to validate the assumptions that go into estimating total redds in non-index reaches.

Table 1: Estimates of mean net error and total redds for each reach.

| Reach | Type | Index.Reach | Net.Error | Net.Error.CV | Redds.Counted | Redds.Est | Redds.CV |

| Total |  | $400(0.31)$ | $621(0.25)$ |
|  |  |  |  |

## Discussion

We have estimated the number of steelhead redds based on redd surveys, while incorporating potential observation error. After translating these to estimates of spawners by origin, we can then compare the spawner estimates to escapement estimates made using PIT tags, and estimate a pre-spawn mortality rate (Table 4). Taking the total PIT-tag based escapement estimate to the Wenatchee (after subtracting the 327 hatchery and 66 wild fish removed at Tumwater, as well as the 27 hatchery fish removed at Dryden, and the 56 and 8 deaths to hatchery and wild fish due to harvest), and subtracting the total estimate of spawners, including the tributaries, then dividing by the total escapement
estimate provides an estimate of pre-spawn mortality across the entire Wenatchee population. We did this for natural and hatchery origin fish, and found that natural fish had a higher pre-spawn mortality rate this year.

Table 4: Wenatchee pre-spawn mortality rates.

| Origin | Pre-spawn_Mort | CV |
| :--- | ---: | ---: |
| Natural | 0.26 | 0.0009 |
| Hatchery | 0.09 | 0.0077 |

## Caveats

The predictions of surveyor net error were made using a model that had been fit to data in the Methow. Most covariates in the Wenatchee were within the range of values in the Methow study, but mean discharge was higher in all reaches in the Wenatchee than in the modeled reaches in the Methow (Figure 3). The mean discharge in the Methow study was 1069.2, while it was 3837.5 in the Wenatchee reaches in 2016. That difference alone would change net error predictions by 0.5 , not an insignificant amount. However, the observed covariate values in the Wenatchee did not lead to unrealistic estimates of net error. The ranges of net error estimates for the Methow study and the Wenatchee in 2016 were very similar.

## Net Error Covariates

Net error covariate values from the study in the Methow and the predicted reaches in the Wenatchee.

## Executive Summary

In 1997, Wenatchee River summer steelhead, as part of the upper Columbia River evolutionarily significant unit (ESU), were listed as threatened under the Endangered Species Act (ESA). To address concerns about effects of hatchery supplementation, the hatchery program for hatchery produced (HOR) summer steelhead to be planted in the Wenatchee River changed from using mixed ancestry broodstock collected in the Columbia River to using Wenatchee River broodstock collected in the Wenatchee River. Three monitoring and evaluation (M\&E) indicators were developed to measure the genetic effects of hatchery production on wild fish populations. To address these indicators, temporal collections of tissue samples from Wenatchee River hatchery-produced (HOR) and natural origin (NOR) adults captured and sampled at Dryden and Tumwater dams and from NOR juveniles from three Wenatchee River tributaries and the Entiat River were surveyed for genetic variation with 132 genetic (SNPs) markers. Peshastin Creek (a Wenatchee River tributary) and the Entiat River served as no-hatchery-outplant controls, meaning they have stopped receiving HOR juvenile outplants. As per the M\&E plan, we interrogated these data for the presence or absence of spatial and temporal trends in allele frequencies, genetic distances, and effective population size.

Allele frequencies - Changes to the summer steelhead hatchery supplementation program had no detectable effect on genetic diversity of wild populations. On average, HOR adults had higher minor allele frequencies (MAF) than NOR adults, which may simply reflect the mixed ancestry of HOR adults. Both HOR and NOR adults had MAF similar to juveniles collected in spawning tributaries and in the Entiat River. There was no temporal trend in allele frequencies or observed heterozygosity in adult or juvenile collections and allele frequencies in control populations were no different than those still receiving hatchery outplants. This suggests that the hatchery program has had little effect on allele frequencies since broodstock sources changed in 1998.

Genetic distances - As intended, interbreeding of Wenatchee River HOR and NOR adults reduced the genetic differences between Wells Hatchery HOR adults and Wenatchee River NOR adults observed in the first few years after changing the broodstock collection protocol. Though there were detectable genetic differences between HOR and HOR adults, the magnitude of that
difference declined over time. HOR adults were genetically quite different from NOR adults and juveniles based on pair-wise $F_{\text {ST }}$ and principal components analysis (PCA), most likely because of the much smaller effective population size $\left(N_{\mathrm{b}}\right)$ in the hatchery population (see below). Pairwise $F_{\text {ST }}$ estimates and genetic distances between HOR and NOR adults collected the same year declined over time suggesting that the interbreeding of HOR and NOR adults in the hatchery (and presumably in the wild) is slowly homogenizing Wenatchee River summer steelhead. Analyses using brood year (the year fish were hatched, determined using scale-based age estimates) were inconclusive because of limitations of the data.

Effective population size $\left(N_{\mathrm{b}}\right)$ - Although the effective population size of the Wenatchee River hatchery summer steelhead program was consistently small, it does not appear to have caused a reduction in the effective population size of wild populations. On average, estimates of $N_{\mathrm{b}}$ were much lower and varied less for HOR adults than for NOR adults and juveniles. Estimates of $N_{\mathrm{b}}$ for HOR adults declined from the earliest brood years to a stable new low value after broodstock practices were changed in 1997. There was no indication that this had any effect on $N_{\mathrm{b}}$ in NOR adults and juveniles; $N_{\mathrm{b}}$ estimates for NOR adults and juveniles were, on average, higher and varied considerably over the time period covered by our dataset (1998-2010) and showed no temporal trend.

## Introduction

The National Marine Fisheries Service (NMFS) recognizes 15 Evolutionary Significant Units (ESU) for west coast steelhead (Oncorhynchus mykiss). The Upper Columbia ESU, which contains steelhead in the Wenatchee Basin, was listed as endangered under the Endangered Species Act (ESA) in 1997. Included in this listing were the Wells hatchery steelhead (program initiated in the late 1960s) that originated from a mixed group of native steelhead and are considered to be genetically similar to natural spawning populations above Wells Dam. Juvenile steelhead from Wells Fish Hatchery was the primary stock released into the Wenatchee River (Murdoch et al. 2003). The 1998 steelhead status review identified several areas of concern for this ESU including the risk of genetic homogenization due to hatchery practices and the high proportion ( $65 \%$ for the Wenatchee River) of hatchery fish present on the spawning grounds (Good et al. 2005). The Biological Review Team (BRT) further identified the relationship between the resident and anadromous forms of $O$. mykiss and possible changes in the population structure ('genetic heritage of the naturally spawning fish') in the basin as two areas requiring additional study. Furthermore, the West Coast Steelhead BRT (2003) recommended that stocks in the Wenatchee, Entiat, and Methow rivers, within the Upper Columbia ESU, be managed as separate populations.

A review of the presence of resident $O$. mykiss in the Upper Columbia ESU (Good et al. 2005) shows that rainbow trout are relatively abundant in upper Columbia River tributaries currently accessible to steelhead as well as in upriver tributaries unavailable to anadromous access by Chief Joseph and Grand Coulee dams (Kostow 2003). U.S. Fish and Wildlife Service (USFWS) biologists surveyed the abundance of trout and steelhead juveniles in the Wenatchee, Entiat, and Methow river drainages in the mid-1980s and found adult trout (defined as those with fork length $>20 \mathrm{~cm}$ ) in all basins (Mullan et al. 1992). The results also supported the hypothesis that resident $O$. mykiss are more abundant in tributary or mainstem areas upstream of the areas used by steelhead for rearing. No samples of rainbow trout from the Wenatchee were available for this study.

In addition to the mixed ancestry Wells Hatchery steelhead, Skamania Hatchery (Washougal River steelhead ancestry) steelhead were also released into the Wenatchee River basin for several years in the late 1980s (L. Brown, Washington Dept. of Fish and Wildlife [WDFW], personal communication). In 1996, broodstock for the Wenatchee River steelhead program were collected from Priest Rapids Dam and Dryden (rkm 24.9) and Tumwater (rkm 52.6) dams on the Wenatchee River. Because of the ESA listing, broodstock collection after 1996 was restricted to the Wenatchee River in an effort to develop a localized broodstock (Murdoch et al. 2003). Thus, starting in 1998, all juvenile steelhead released into the Wenatchee River and Wenatchee River tributaries were offspring of only Wenatchee River captured broodstock.

In response to the need for evaluation of the supplementation program, both a monitoring and evaluation plan (Murdoch and Peven 2005) and the associated analytical framework (Hays et al. 2006) were developed for the Habitat Conservation Plans Hatchery Committee through the joint effort of the fishery co-managers (Confederated Tribes of the Colville Reservation [CCT], NMFS, USFWS, WDFW, and Yakama Nation [YN]) and Chelan County, Douglas County, and Grant County Public Utility Districts (PUD). These reports outline 10 objectives to be applied to various species assessing the impacts of hatchery operations mitigating the operation of Rock Island and Rocky Reach Dams. This report pertains to Wenatchee River basin steelhead ( $O$. mykiss) and the steelhead supplementation program as addressed by objective 3 , specifically the first three evaluation indicators.

Objective 3: Determine if genetic diversity, population structure, and effective population size have changed in natural spawning populations as a result of the hatchery program. Additionally, determine if hatchery programs have caused changes in phenotypic characteristics of natural populations.

### 3.1 Allele Frequency

### 3.2 Genetic Distances Between Populations

### 3.3 Effective Spawning Population

To address these evaluation indicators the WDFW Molecular Genetics Lab (MGL) obtained pertinent tissue collections and samples, surveyed genetic variation with SNP markers using our standard laboratory protocols, and calculated the relevant genetic metrics and statistics. We used collections from both the Entiat River and Wenatchee River basins. Both have received hatchery plants from non-local stocks [i.e. Entiat was stocked with both Wenatchee and Wells program juveniles averaging 12 K and 18 K respectively during 1995-2001, and Wenatchee received on average 177 K juveniles from the Wells program during 1995-2001; (Good et al. 2005)], and both have all or some part of the basin designated as natural production "reference" drainage - no hatchery outplanting (i.e., the entire Entiat Basin, and Peshastin Creek in the Wenatchee River basin) (Good et al. 2005).

## Materials and methods

## Sample collections

To address objectives 3.1 through 3.3, we obtained samples from hatchery (HOR, adipose fin clipped) and natural origin (NOR, adipose fin intact) adult summer steelhead captured at Dryden or Tumwater diversion dams in the summer and fall of 1997 through 2009 (excepting 2004 and 2005; Table 1). All or some fraction of these fish was later used as hatchery broodstock the calendar year following the sampling year. In order to keep things simple we have reported years as the spawning year, i.e., the calendar year the fish were spawned, not the calendar year they were captured.

To address objective 3.2, it was necessary to have samples from natural origin fish from each of the spawning populations in the basin. It is difficult to obtain adult samples from known spawning populations due to the life history and behavior of steelhead, without tributary weirs or some other blocking method of collection. The NOR adult samples used as broodstock collected from Dryden and Tumwater Dams were a mixed collection representing all of the spawning populations located upstream. Therefore to determine population substructure within the basin we obtained collections of juvenile fish from smolt traps located within tributaries representing three major populations in the basin and from the Entiat River (Chiwawa River, Nason Creek, and Peshastin Creek; Table 2). We also obtained two collections of juvenile fish caught in a
smolt trap in the lower Wenatchee River. These, like the NOR adult collections, were a mixed collection presumably representing all populations located upstream. Fin tissue was taken from each fish and preserved in $95 \%$ ethanol.

## Sample processing

Fin tissue samples were processed for 1468 HOR and NOR adult steelhead broodstock (Table 1) and for 1542 juvenile $O$. mykiss from the Wenatchee and Entiat Rivers (Table 2). Samples were genotyped at 152 single nucleotide polymorphism loci (SNPs, Tables 3, 4). We originally proposed to use microsatellites, but WDFW MGL and other regional genetic laboratories (Columbia River Inter-Tribal Fish Commission [CRITFC], Idaho Fish and Game [IDFG], USFWS) are moving toward using SNPs and they provide the same kinds of information with faster processing. Twenty SNP loci were developed to discriminate among trout species; 14 distinguish $O$. mykiss from coastal cutthroat trout ( $O$. clarkii clarkii) and westslope cutthroat ( $O$. clarkii lewisi), and 6 distinguish steelhead and coastal cutthroat from westslope cutthroat (Table 4). The remaining 132 SNP loci were developed to be used for population structure, parentage assignment, or other population genetic studies of $O$. mykiss (Table 3). These markers comprised the current standard set of SNP markers used for genetic studies of $O$. mykiss at WDFW MGL.

We used Qiagen DNEasy ${ }^{\circledR}$ kits (Qiagen Inc., Valencia, CA), following the recommended protocol for animal tissues, to extract and isolate DNA from fin tissue. SNP genotypes were obtained through PCR and visualization on Fluidigm EP1 integrated fluidic circuits (chips). Protocols followed Fluidigm's recommendations for TaqMan SNP assays as follows: Samples were pre-amplified by Specific Target Amplification (STA) following Fluidigm's recommended protocol with one modification. The 152 assays were pooled to a concentration of 0.2 X and mixed with 2X Qiagen Multiplexing Kit (Qiagen, Inc., Valencia CA), instead of TaqMan PreAmp Master Mix (Applied Biosystems), to a volume of $3.75 \mu$ l, to which $1.25 \mu \mathrm{l}$ of unquantified sample DNA was added for a total reaction volume of $5 \mu$ l. Pre-amp PCR was conducted on a MJ Research or Applied Biosystems thermal cycler using the following profile: $95^{\circ} \mathrm{C}$ for 15 min followed by 14 cycles of $95^{\circ} \mathrm{C}$ for 15 sec and $60^{\circ} \mathrm{C}$ for 4 minutes. Post-PCR reactions were diluted with $20 \mu \mathrm{dH} 2 \mathrm{O}$ to a final volume of $25 \mu \mathrm{l}$.

Specific SNP locus PCRs were conducted on the Fluidigm chips. Assay loading mixture contained 1X Assay Loading Reagent (Fluidigm), 2.5X ROX Reference Dye (Invetrogen) and 10X custom TaqMan Assay (Applied Biosystems); sample loading mixture contains 1X TaqMan Universal PCR Master Mix (Applied Biosystems), 0.05X AmpliTaq Gold DNA polymerase (Applied Biosystems), 1X GT sampling loading reagent (Fluidigm) and $2.1 \mu \mathrm{~L}$ template DNA. Four $\mu \mathrm{L}$ assay loading mix and $5 \mu \mathrm{~L}$ sample loading mix were pipetted onto the chip and loaded by the IFC loader (Fluidigm). PCR was conducted on a Fluidigm thermal cycler using a two step profile. Initial mix thermal profile was $70^{\circ} \mathrm{C}$ for $30 \mathrm{~min}, 25^{\circ} \mathrm{C}$ for $5 \mathrm{~min}, 52.3^{\circ}$ for $10 \mathrm{sec}, 50.1^{\circ} \mathrm{C}$ for $1 \mathrm{~min} 50 \mathrm{sec}, 98^{\circ} \mathrm{C}$ for $5 \mathrm{sec}, 96^{\circ} \mathrm{C}$ for $9 \mathrm{~min} 55 \mathrm{sec}, 96^{\circ} \mathrm{C}$ for $15 \mathrm{sec}, 58.6^{\circ} \mathrm{C}$ for 8 sec , and $60.1^{\circ} \mathrm{C}$ for 43 sec . Amplification thermal profile was 40 cycles of $58.6^{\circ} \mathrm{C}$ for $10 \mathrm{sec}, 96^{\circ} \mathrm{C}$ for 5 $\sec , 58.6^{\circ} \mathrm{C}$ for 8 sec and $60.1^{\circ} \mathrm{C}$ for 43 sec with a final hold at $20^{\circ} \mathrm{C}$.

The SNP assays were visualized on the Fluidigm EP1 machine using the BioMark data collection software and analyzed using Fluidigm SNP genotyping analysis software. To ensure all SNP markers were being scored accurately and consistently, all data were scored by two researchers and scores of each researcher were compared. Disputed scores were called missing data (i.e., no genotype).

## Evaluation of loci

A two-tailed exact test of Hardy-Weinberg equilibrium (HWE) was performed for each locus in each collection or population using the Markov Chain method implemented in GENEPOP v4.1 (dememorization number 1000, 100 batches, 1000 iterations per batch; Raymond and Rousset 1995; Rousset 2008). Significance of probability values was adjusted for multiple tests using false discovery rate (Verhoeven et al. 2005). $F_{\text {IS }}$, a measure of the fractional reduction in heterozygosity due to inbreeding in individuals within a subpopulation and an additional indicator of scoring issues, was calculated according to Weir and Cockerham (1984) using GENEPOP v4.1. Allele frequencies were calculated using CONVERT v1.0 (Glaubitz 2004). Expected and observed heterozygosities were calculated using GDA v1.1 (Lewis and Zaykin 2001).

## Allele frequencies, genetic distances and population differentiation

To evaluate Q1 of Objective 3.1 and 3.2, we evaluated trends and patterns in allele frequencies, genetic distances and population differentiation. To test for temporal patterns in allele frequencies, we compared sample or spawn year to two diversity metrics, allele frequency and observed heterozygosity, from each adult and juvenile collection. Each SNP locus had only one or two alleles, so we used the minor allele frequency (MAF) of each SNP locus for each adult collection and averaged across loci. We also calculated the average observed heterozygosity (Ho) for each SNP locus within each adult and juvenile collection. We examined the presence or absence of a temporal trend in average allele frequency and observed heterozygosity with logistic regression analysis in R (R Development Core Team 2009).

To partition genetic variance into temporal, spatial (juvenile) and origin (adult) fractions, we performed hierarchical analysis of molecular variance (AMOVA) using ARLEQUIN v3.0 (Excoffier et al. 2005) with 1,000 permutations. We performed this analysis separately for juvenile and adult collections. Juveniles were grouped by sampling location (tributary) and adults were grouped by origin (HOR or NOR). To estimate the magnitude of genetic differences among temporal and spatial collections we calculated pairwise $F_{\text {ST }}$ estimates among collections using FSTAT (Goudet 1995) with 1000 permutations. Statistical significance was adjusted using false discovery rate (Verhoeven et al. 2005).

To evaluate the temporal changes in genetic relationships, we compared spawn year to within spawn year pairwise $F_{\text {sT }}$ estimates between NOR and NOR adults using beta regression (Simas and Rocha 2010). We used beta regression because the dependent variable was bound by zero and one but not binomial. Analysis was performed in R (package "betareg", Cribari-Neto and Zeileis 2010), with a $\log \log$ link.

We used principal component analyses (PCA) to explore the relationship between the covariation among the SNP loci within each collection and genetic differentiation between HOR and NOR collections, and to determine if the degree of differentiation has changed with time. Since each SNP is represented by only two alleles, only one allele per SNP is necessary to fully describe the covariation among all SNPs. We used matlab® scripts (2007a, The Mathworks, Natlick, MA)
to calculate the principal components from SNP allele frequencies using only the major allele (1MAF) for each SNP. We defined the major allele as the allele with the higher mean frequency across all collections, regardless of its status within any individual collection. We conducted three PCA analyses using: (1) all adult samples, aggregated based on origin (HOR versus NOR) and spawn year (i.e., the year the adult fish were used as broodstock) ( $\mathrm{N}=1437$, 22 collections), (2) same as \#1, but with the addition of all juvenile samples ( $\mathrm{N}=2938$, 37 collections), and (3) only those adults samples with available age information (Mike Hughes, WDFW, personal communication) aggregated based on origin, and spawn year or brood year (i.e., the year the fish were hatched) ( $\mathrm{N}=1313,20$ spawn-year or 25 brood-year collections).

Molecular differentiation between HOR and NOR adults within a year was calculated based on principal component scores using Euclidian distances. We calculated pair-wise Euclidian distances between HOR and NOR fish within a spawn year or brood year using the first three principal components, and standardized each distance by subtracting from it the mean Euclidian distance calculated across all pair-wise distances. We used Mahalanobis distances to calculate the variation among HOR and NOR collections (calculated separately), again using the first three principal components. Here, we calculated Mahalanobis distances as the Euclidian distances between each collection and the centroid of all collections (HOR and NOR combined), but the Euclidian distances are scaled based on the dispersion of collections around the centroid (i.e., the variance). Euclidian and Mahalanobis distances were calculated using MATLAB scripts.

## Effective spawning population

To evaluate Q 1 of Objective 3.3, we estimated $N_{e}$ using the single-sample linkage disequilibrium methods implemented in the program LDNE (Waples and Do 2008). This method requires that you input the $P_{\text {crit }}$ value, the minimum frequency at which alleles were included in the analysis, since results can be biased depending on this setting (Waples and Do 2010). SNP markers typically have only one or two alleles; if one of two alleles is excluded based on its frequency in the collection it essentially excludes the locus, reducing the overall dataset. Therefore, we used $P_{\text {crit }}$ values ranging from 0.1 to 0.001 to evaluate whether trends in $N_{\mathrm{e}}$ changed given which loci were used. Confidence intervals were calculated using a jackknife procedure.

We calculated an estimate of $N_{\mathrm{e}}$ for all adult and juvenile collections individually. However, the intention of an integrated hatchery program such as the Wenatchee River steelhead hatchery program is that HOR and NOR fish are integrated and progress as a single population through intentional interbreeding in the hatchery and presumed natural interbreeding in the wild. Thus, we also combined annual HOR and NOR collections to calculate an overall $N_{\mathrm{e}}$ estimate as has been done in other genetic monitoring and evaluation analyses (e.g., Small et al. 2007, [Chinook salmon, O. tshawytscha]).

Estimates of $N_{e}$ from linkage refer to the generations that produced the sample. To calculate the ratio of effective population size to census size $\left(N_{\mathrm{e}} / N\right)$, we obtained the number of fish spawned in the hatchery (1993 through 2006, i.e., those that produced the adipose fin clipped adults that returned to spawn in the Wenatchee River 1998 through 2010) and the estimated escapement of fish spawning naturally (HOR and NOR separately) for the same time period. Estimates of census population size in spawning tributaries was obtained by multiplying the fraction of redds counted within tributaries (Chad Herring, WDFW, unpublished data) by the total Wenatchee River census population estimate (Andrew Murdoch, WDFW, unpublished data). To calculate $N_{e} / N$, we performed two analyses. First, for adults, we assumed a five year generation time for natural origin adults and a four year generation time for hatchery origin adults and divided the $N_{\mathrm{e}}$ estimate by the census population estimate from four or five years earlier. For juveniles, we assumed an age at outmigration of two years and divided the $N_{\mathrm{e}}$ estimates by the estimate of census population size for the appropriate tributary. Second, we used available adult age data to parse individuals into cohorts originating in brood years (rather than spawn years) and then used LDNE to estimate $N_{\mathrm{e}}$ from cohort collections. We performed both analyses to make full use of all available data; age data were not available for many adults, and because of variable survival and sampling not all cohorts had sufficient numbers of HOR and NOR adults. According to Luikart et al. (2010), estimates produced using linkage disequilibrium should be interpreted as something between effective population size $\left(N_{e}\right)$ and the effective number of breeders $\left(N_{b}\right)$. Using cohorts, the estimate produced by LDNE is clearly an estimate of $N_{\mathrm{b}}$ rather than $N_{\mathrm{e}}$. In order to keep things simple, we have referred to all estimates as $N_{\mathrm{b}}$.

## Results and Discussion

## Collections and samples received

From 1468 samples from HOR and NOR adult steelhead broodstock, 1437 produced sufficient genetic data for further analysis (Table 1). From 1542 samples from NOR juvenile steelhead from Wenatchee River tributaries and the Entiat River, 1501 produced sufficient genetic data for further analysis and were genetically identified as $O$. mykiss (Table 2). Samples genetically identified as $O$. clarki ( 2 samples from the Chiwawa River, 1 from the Entiat River) or $O$. clarki/O. mykiss hybrids (4-lower Wenatchee River, 4 - Nason Creek, 4 - Chiwawa River, and 1 - Entiat River) were omitted from further analysis.

## Evaluation of loci

Three loci showed deviations from HWE in 10 or more of 37 Wenatchee steelhead collections before correcting for multiple tests (AOmy016, AOmy051, AOmy252, Table A1) indicating possible scoring issues. These loci were omitted from further analysis. Nine of the remaining loci were monomorphic or nearly monomorphic in all collections (average MAF < 0.1, AOmy023, AOmy028, AOmy123, AOmy129, AOmy132, AOmy209, AOmy229, AOmy270, AOmy271, Table A1) contributing little or nothing to analytical power. These loci were also omitted from further analysis. No genetic data was available for collection 10FD due to poor PCR amplification at locus AOmy213 for the entire collection. AOmy213 had a relatively low MAF in most collections so rather than re-processing this collection at this locus or running different sets of loci for different tests, we omitted this locus from further analysis. Only six tests of deviation from HWE were significant after correcting for 4348 tests using false discovery rate. Two of these tests were in loci already omitted. The remaining four tests were spread among the remaining loci, indicating no more loci needed to be omitted from further analysis.

## Objective 3.1, 3.2 - Allele frequencies and Genetic distances

## Allele frequencies

Average MAF of SNP loci ranged from 0.00 to 0.60 in HOR adult collections and from 0.00 to 0.61 in NOR adult collections (Table A1). Observed heterozygosity ranged from 0.00 to 0.75 in HOR adult collections and from 0.01 to 0.67 in NOR adult collections. Juvenile collections produced similar ranges of MAF and Ho (Table A1). Average MAF and Ho of HOR adult collections appeared to be greater than those of natural origin collections. However, logistic regression analysis indicated there was no significant temporal trend in either diversity statistic (Figure 1). Similarly, there was no consistent temporal trend in MAF or Ho of juvenile collections (Figure 2). Both the Chiwawa River and Nason Creek, the two tributaries that currently still receive hatchery juvenile outplants, both appeared to have declining allele frequencies, but neither was statistically significant ( $P>0.90$ ). However, the power to detect significant trends was limited by the small sample sizes ( $\mathrm{n}=3$ sample years).

## Analysis of Molecular Variance

Analysis of molecular variance (AMOVA) of adult collections (i.e., temporal and origin structure) indicated most of the genetic variance was among individuals or among individuals within populations ( $99.04 \%$ ). Most of the remaining variance was temporal variation within hatchery and natural origin groups ( $0.61 \%$ ) with the remaining variation from origin ( $0.35 \%$ ). AMOVA of juvenile collections (i.e., spatial structure) indicated most of the genetic variance was among individuals ( $98.44 \%$ ) or among individuals within populations ( $0.94 \%$ ). Most of the remaining variance existed among temporal collections within tributary collections ( $0.37 \%$ ) with the smallest fraction as among tributary variance ( $0.24 \%$ ). Thus, overall, there was more variability among years than among tributaries or origins, but no trend in the temporal variability.

## Pair-wise $\mathrm{F}_{\text {ST }}$ estimates

HOR adults were genetically different that NOR adults as estimated by $F_{\text {ST }}$ (full pair-wise table in Table A2, all pair-wise $F_{\text {ST }}$ estimates with $P$-values $\leq 0.05$ before correcting for multiple tests
were significantly different from zero after correcting for multiple tests using false discovery rate). On average, HOR adult collections were as different from one another (mean $F_{\mathrm{ST}}=0.011$ ) as they were from NOR adult collections among years (mean $F_{\mathrm{ST}}=0.009$ ) or from NOR adult collections within years (mean $F_{\mathrm{ST}}=0.010$ ). Among year comparisons of NOR adult collections were, on average, nearly an order of magnitude lower (mean $=0.002$ ). These patterns held whether spawn year or brood year (data not shown) was used to group individuals. Over time, within spawn year pair-wise $F_{\text {ST }}$ estimates between HOR and NOR adults declined over time ( $\beta$ $=-0.014, P=0.0185$; Figure 3), suggesting that the integration of hatchery and wild fish is slowly genetically homogenizing the groups. That relationship disappeared when adults were grouped by brood year (i.e., comparing fish produced the same year) and all brood years were used ( $\beta=-0.009, P=0.615$, data not shown). However, when the dataset was restricted to just those brood years when all typical (age at maturation frequency among all years $>0.10$ ) age classes were present in the dataset $(\mathrm{HOR}=$ age 3,$4 ; \mathrm{NOR}=$ age $4,5,6$; brood years 1996-1998, 2004-2005) a non-significant ( $P=0.278$ ) negative relationship ( $\beta=-0.12$ ) of $F_{\mathrm{ST}}$ and brood year was apparent. When the data were further restricted to just the years after the hatchery program changed to only collecting broodstock in the Wenatchee River (brood years 1998, 2004-2005), the slope was also negative ( $\beta=-0.09$ ), but the relationship was not statistically significant ( $P=$ 0.962 ).

Within tributary among sample year pair-wise comparisons of juvenile collections were, on average, only very slightly smaller than comparisons among tributaries ( 0.005 vs .0 .006 , respectively, Table 5, all pair-wise $F_{\text {ST }}$ estimates with $P$-values $\leq 0.05$ before correcting for multiple tests were significantly different from zero after correcting for multiple tests using false discovery rate). Nason Creek and Peshastin Creek on average showed higher among sample year $F_{\text {ST }}$ estimates ( 0.010 and 0.007 , respectively) than the Chiwawa or Entiat Rivers ( 0.004 and 0.002 , respectively). The pair-wise comparison of the two collections of lower Wenatchee River smolts, presumably a mix of Chiwawa, Nason, Peshastin smolts and smolts from other spawning tributaries, was an order of magnitude smaller $\left(F_{\mathrm{ST}}=0.0002\right)$, and not significantly different than zero (Table 5). There was no temporal trend in pair-wise comparisons of juvenile collections. However with, at most, four annual collections, detecting any temporal trend was unlikely. We also had no collections from years prior to 1998 (the first year of new hatchery program
broodstock collecting protocols) with which to compare contemporary data, nor could we find any reports or papers containing pre-hatchery-program-change genetic comparisons among Wenatchee River tributary populations, making it impossible to determine whether or not changing the hatchery program has had any effect at all on population structure. However, these data will be useful for future studies.

## Principal Components

Each principal component analysis (Figures 4,5) indicated that the genetic structure among HOR collections differed from that among NOR collections, and that this difference has decreased with time. When adult fish were aggregated based on origin and spawn-year, there was a clear differentiation between HOR and NOR adult collections along PC 1, and a separation among HOR collections, differentiating the early spawn-years (1998 - 2003) from the later spawn-years (2004 - 2010) along PC 2 and PC 3, respectively (Figure 4). The pair-wise genetic distances between HOR and NOR collections from the same spawn year (i.e., the HOR and NOR fish used as broodstock within the same year) decreased from the largest distance in 1998 to small distances in 2009 and 2010, although the smallest distance occurred in 2004 (Figure 4, top right). That is, within hatchery broodstock, the genetic difference between HOR and NOR fish decreased, on average, from 1998 to 2010, and the decrease appeared to be a mutual convergence of NOR fish shifting right along PC 1 and HOR fish shifting downward along PC 2 and PC 3. This increasing similarity in adult fish mirrored that seen in within year pair-wise $F_{\text {ST }}$ estimates between HOR and NOR adults which also declined over time (Figure 3).

Overall, there was considerably more genetic variation among the HOR collections than there was among the NOR collections with average Mahalanobis distances (distance between each collection and the overall centroid $[0,0,0]$ ) among the HOR and NOR collections being 4.2 and 1.5 , respectively. Since each NOR collection was generally composed of 3-4 brood-years, while HOR collections rarely were composed of more than two brood-years, we attributed the lower year-to-year genetic variability of the NOR broodstock to the greater homogenizing effect of including four or more brood-years compared with only two brood years for the HOR broodstock.

Including the 15 juvenile collections, along with the 22 adult collections, did not materially alter the principal component structure (Figure 6), although the total genetic variation accounted for by the three principal components decreased from $44 \%$ using only the adults to $33 \%$ when juveniles were included. For the most-part, the juvenile fish appeared intermediate between HOR and NOR fish, but there was greater overlap in principal component scores (and therefore greater genetic similarity) of the juvenile and NOR collections, than of the juvenile and HOR collections. The average Euclidian distance between the juvenile and HOR collections was 0.49 , compared to 0.23 between the juvenile and NOR collections, which was no different than 0.23 and 0.22 for the within juvenile and NOR collections, respectively.

By using the available adult age data, we were able to compare the genetic differentiation among the same set of fish when they are aggregated by origin (hatchery versus natural) and brood-year (year fish were hatched) with aggregates based on origin and spawn-year (year adult fish were spawned). A brood-year analysis compares within a year the genetic diversity generated from hatchery broodstock with that naturally produced in the spawning grounds. A spawn-year analysis compares the HOR and NOR genetic diversity that was mixed among cohorts of the parental generations. The same basic pattern of genetic structure that we have seen in spawnyear analyses (Figure 4, Figure 6, and the right side of Figure 5) also occurred in the brood-year analysis (left side of Figure 5). That is, from Figure 5 we saw (1) that HOR and NOR fish were differentiated from each other; (2) there was considerably more genetic variation (temporal variation) among the hatchery-origin collections than there was among the natural-origin collections (for brood-year, Mahalanobis distances $=5.18$ and 0.75 , respectively; for spawn-year, Mahalanobis distances $=4.25$ and 1.25 , respectively), and (3) that the genetic distances between HOR and NOR collections were lower in the more recent brood- and spawn-years, than in the earlier brood- and spawn-years (Figure $7 ; R^{2}=0.41$ or $41 \%, P<0.05$ ). This indicated that the HOR and NOR fish used as broodstock in 2010 were more similar to each other than they were at the inception of the new hatchery program.

The relationship between genetic distance and brood-year was not the same as the relationship between genetic distance and spawn-year. For brood-year, although the slope was negative (i.e.,
trending downward or decreased differentiation with time) and the two most-recent brood years (2005-2006) showed relatively small HOR and NOR adult differentiation, the negative slope was not significantly different from zero and the regression accounted for only $7 \%$ of the variation. This was likely the result of insufficient sampling of certain age classes from many brood years (especially from NOR adults) due to two un-processed sample years (2005 and 2006).

## Objective 3.3 - Effective spawning population

There was no difference in the temporal trends in estimates of $N_{b}$ with $P_{\text {crit }}$ set from 0.1 to 0.001 (Figure 8, data not shown for all collections), so we have reported only results with $P_{\text {crit }}=0.001$, i.e., the full genetic dataset. Using either spawn-year or brood year, estimates of NOR adult $N_{\mathrm{b}}$ were higher and varied more than those of HOR adults (Figures 9, 10), concordant with the PCA analysis. Estimates for HOR adults ranged from 17 to 174 (by spawn year, mean $=65$ ) or from 6 to 130 (by brood year, mean = 39). Estimates for NOR adults ranged from 36 to 982 (by spawn year, mean $=405)$ or from 59 to 2966 (by brood year, mean $=645$ ). Many $N_{\mathrm{b}}$ estimates for NOR adults had confidence intervals extending to infinity on the upper bound. This reflected the difficulty in obtaining precise estimates of $N_{\mathrm{b}}$ for large populations (Waples and Do 2010).

Estimates of $N_{\mathrm{b}}$ for HOR steelhead dropped by approximately half from 1994, when broodstock were still collected at Wells Hatchery, to 1998, when the program used Wenatchee River trapped adults only, suggesting an effect of changing broodstock collection practices, which began in 1997 (Figures 8, 9). Since 1997, the hatchery population $N_{\mathrm{b}}$ remained at a relatively stable lower level (Figures 8, 9, and 10). There was no obvious change in $N_{\mathrm{b}}$ for NOR steelhead since 1993; the $N_{\mathrm{b}}$ estimate for 1993 was the largest, however the confidence interval overlapped estimates from many other years. The temporal trend in $N_{\mathrm{b}}$ estimates from combined collections mirrored those of the HOR collections alone, though estimates using combined collections were slightly larger (Figure 11).

As with $N_{\mathrm{b}}$ estimates, estimates of the ratio of $N_{\mathrm{b}} / N$ for NOR adults varied more than those of HOR adults (Figures 12, 13). However, using spawn year, i.e., mixtures of cohorts, the average $N_{\mathrm{b}} / N$ ratio for HOR adults was equal to that of NOR adults (mean $N_{\mathrm{b}} / N=0.26$ ), whereas when using brood year, the average $N_{\mathrm{b}} / N$ ratio for NOR adults was double that of HOR adults (NOR
average $=0.40$, HOR average $=0.20$ ). This is likely a consequence of the homogenizing effect of mixed cohorts. Estimates of $N_{\mathrm{b}}$ for HOR adults using spawn year were close to those estimated using brood year because of the lower diversity in age at maturation, whereas for NOR, grouping by brood year produces different estimates than when grouping by spawn year because of higher diversity in age at maturation. Regardless of which estimate was used, there was no temporal trend in $N_{\mathrm{b}} / N$ for either NOR or HOR adults.

## Summary

On average, HOR adults had higher minor allele frequencies (MAF) than NOR adults, and both had similar MAF as juveniles collected in spawning tributaries and in the Entiat River. There was no temporal trend in allele frequencies or observed heterozygosity in adult or juvenile collections and allele frequencies in control populations were no different than those still receiving hatchery outplants suggesting that the hatchery program has had little effect on allele frequencies since 1998.

HOR adults were genetically quite different from NOR adults and juveniles based on pair-wise $F_{\text {ST }}$ and principal components analysis (PCA), most likely because of the much smaller effective population size $\left(N_{\mathrm{b}}\right)$ in the hatchery population. Pair-wise $F_{\mathrm{ST}}$ estimates and genetic distances between HOR and NOR adults collected the same year declined over time suggesting that the interbreeding of HOR and NOR adults in the hatchery (and presumably in the wild) is slowly homogenizing Wenatchee River summer steelhead. Analyses using brood year (the year fish were hatched, determined using scale-based age estimates) were inconclusive because of limitations of the data.

On average, estimates of $N_{\mathrm{b}}$ were much lower and varied less for HOR adults than for NOR adults and juveniles. Estimates of $N_{\mathrm{b}}$ for HOR adults declined from the earliest brood years to a stable new low value after broodstock practices were changed in 1997. There was no indication that this had any effect on $N_{\mathrm{b}}$ in NOR adults and juveniles; $N_{\mathrm{b}}$ estimates for NOR adults and juveniles were, on average, higher and varied considerably over the time period covered by our dataset (1998-2010) and showed no temporal trend. Small $N_{\mathrm{b}}$ sizes increase the risk of loss of
genetic diversity due to inbreeding and random effects (genetic drift). The $N_{\mathrm{b}}$ of the hatchery component of the population may be increased by spawning more families, using specific mating designs, and minimizing variance in reproductive success. However, given the apparent lack of effects overall, changes to the hatchery protocol may not be necessary.

Overall, hatchery practices appear to have had little effect on natural origin Wenatchee summer steelhead neutral genetic diversity or $N_{\mathrm{b}}$. We cannot accurately assess their effects on population structure at this time. However, it is interesting to note that when juvenile collections are analyzed separately from adult collections, Peshastin Creek, which has received fewer hatchery outplants in the past and is currently a refuge from hatchery outplants, is genetically different than other tributaries and the Entiat River (data not shown). On the other hand, the Entiat River, which is also a refuge from hatchery outplants and is not a tributary of the Wenatchee River, is genetically very similar to Nason Creek and the Chiwawa River, both Wenatchee River tributaries. This suggests, though it does not conclude, that within basin population structure may have existed before summer steelhead hatchery production began in the upper Columbia River and that the population structure was eliminated by hatchery influence long before 1998.

## Acknowledgements

We thank Chad Herring, Clint Deason, John Walters and the numerous technicians that sampled these thousands of fish. We thank Sonia Peterson and Sarah Bell for help in the laboratory and thank Maureen Small for help with some analyses. The project was implemented with funding from the Chelan Co. PUD and Washington State general funds.

## Figures

Figure 1. Observed average minor allele frequencies (MAF) and observed heterozygosities (Ho) of 119 SNP loci from 11 annual collections of hatchery-produced (HOR) and natural origin (NOR) adult steelhead from the Wenatchee River. Trend lines are from a logistic regression. Note the X axis does not cross the Y axis at the origin. Neither the slopes nor the intercepts were statistically significant.

Figure 2. Observed average minor allele frequencies (MAF) and observed heterozygosities (Ho) of 119 SNP loci from 15 collections of natural origin juvenile steelhead from Wenatchee River tributaries, the lower Wenatchee River and the Entiat River. There were no consistent temporal trends in MAF or Ho in these collections.

Figure 3. The relationship of time with pairwise $F_{\text {ST }}$ estimates between hatchery-produced (adipose fin clipped) and natural origin (unclipped) adults of the same sample year. The line is the prediction based on beta regression.

Figure 4. Principal component (PC) 1 versus 2 (top left), PC 1 versus 3 (bottom left), and PC 2 versus 3 (bottom right) based on an analysis using all adults aggregated into origin and spawn-year collections. Natural-origin spawn-years are shown in italicized typeface. The percentage within the label of each axis convey the percent of total genetic variance that is accounted for by that axis. Taken together, the three principal components account for $44 \%$ of the total SNP variation. Top right shows pairwise Euclidian distances versus spawn-year, with zero distance equal to average distance across all pairwise distances. Blue line is least-squares fit with $\mathrm{R}^{2}=0.45$.

Figure 5. Principal components (PC) 1 versus 2 (top) and 3 (bottom) for adults aggregated into brood-year (BY; left) and spawn-year (SY; right). Spawn-year analysis is the same as in Figure x1, except fewer individuals per collection were included (see methods). Note that for the SY analysis here PC 2 and 3 are similar to PC 3 and 2, respectively, in Figure x1. Only BY1995 (earliest year with paired hatchery-natural data), BY2000 (extreme PC 1 score), and BY2006 (latest year with paired hatchery-natural data) are labeled. Hatchery- and natural-origin individuals from BY1995, BY2000, and BY2006, returned to spawn (spawn-year) in 1999 (hatchery)/1999-2001 (natural), 2003-2004 (hatchery)/2004 and 2007 (natural), and 2009-2010 (hatchery)/2010 (natural), respectively. These years are labeled in the upper right figure. Only 4 year-old BY 2006 natural-origin fish are represented in the SY 2010 collection.

Figure 6. Principal component (PC) 1 versus 2 (top) and PC 1 versus 3 (bottom) based on an analysis using all adult and juvenile fish aggregated into age (juvenile versus adult), origin (hatchery versus adult) and spawn-year collections.

Figure 7. Pairwise Euclidian distances versus brood-year (top) and spawn-year (bottom), with zero distance equal to average distance across all pairwise distances. Blue lines are least-squares fits, which is not significant $($ slope $=0$ ) for brood-year, but significant (slope $>0$ ) for spawn-year.

Figure 8. Effective population size estimates $\left(N_{\mathrm{b}}\right)$ from Wenatchee River adult hatcheryproduced steelhead annual collections calculated using single sample methods implemented in the program LDNE (Waples and Do 2008). Each line connects annual estimates of $N_{\mathrm{b}}$ estimated with a different value of $P_{\text {crit }}$, the smallest allelic proportion allowed during analysis. With SNP data, omitting an allele omits the locus. Estimates of $N_{\mathrm{b}}$ changed very little when $P_{\text {crit }}$ varied from 0.1 to 0.001 . Setting $P_{\text {crit }}=0.001$ forced the use of all available loci.

Figure 9. Estimates of Wenatchee River steelhead effective number of breeders ( $N_{\mathrm{b}}$ ) estimated using the single sample methods incorporated in the program LDNE (Waples and Do 2008). Estimates of $N_{\mathrm{b}}$ refer to parental (and even grantparental) generations. $N_{\mathrm{b}}$ data were plotted against their estimated parental brood year. We assumed a 5 year generation time for natural origin adults (NOR), a 4 year generation time for hatchery-produced adults (HOR) and an age of smolt outmigration of age 2 for smolt collections from Wenatchee River tributaries (Chiwawa River, Nason Creek, Peshastin Creek), the lower Wenatchee River, and the Entiat River. Bars represent the $95 \%$ confidence interval estimated by jackknife procedure. Bars that exceed the upper limit of the Y axis are labeled with the upper bound (Inf. = infinity).

Figure 10. Estimates of $N_{\mathrm{b}}$ for collections of hatchery-produced (HOR) and natural origin (NOR) Wenatchee River summer steelhead grouped by brood year rather than spawn year. Brood year was estimated using scale-based age data. Error bars that extend past the top of the chart are all bounded by infinity.

Figure 11. Estimates of $N_{\mathrm{b}}$ for combined annual adult hatchery-produced (HOR) and natural origin (NOR) steelhead and for HOR adults alone. The temporal patterns are similar, though estimates from combined collections are larger than those from HOR collections alone.

Figure 12. $N_{\mathrm{b}} / N$ ratios for hatchery-produced (HOR) and natural origin (NOR) adult Wenatchee River summer steelhead grouped by spawn year. The average $N_{\mathrm{b}} / N$ ratios are not different, though in later years NOR adults appear to have lower $N_{\mathrm{b}} / N$ ratios.

Figure 13. $N_{\mathrm{b}} / N$ ratios for hatchery-produced (HOR) and natural origin (NOR) adult Wenatchee River summer steelhead collections with individuals grouped in brood years rather than spawn years. Individual brood year was estimated using scale-based age data.

$P$-values in bold were significant at $\alpha=0.05$ after correcting for multiple tests using false discovery rate.

## Appendix F

NPDES Hatchery Effluent Monitoring 2016

## NPDES MONITORING FOR WDFW FACILITIES

All WDFW hatcheries monitor their discharge in accordance with the National Pollutant Discharge Elimination System (NPDES) permit. This permit is administered in Washington by the Washington Department of Ecology under agreement with the United States Environmental Protection Agency. The previous permit was extended until March 31, 2016. The current permit was renewed effective April 1, 2016 and will expire March 31, 2021.

Facilities are exempted from sampling during any month that pounds of fish on hand fall below $20,000 \mathrm{lbs}$ and pounds of feed used fall below $5,000 \mathrm{lbs}$, with the exception of offline settling basin discharges which are to be monitored once per month when ponds are in use and discharging to receiving waters. Inactive permitted facilities retain a permit but are not required to monitor discharges because the pounds of fish and pounds of feed remain below monitoring guideline set by the permit.

Sampling at permitted facilities includes the following parameters:
$<$ FLOW Measured in millions of gallons per day (MGD) discharge.
$<$ SS EFF Average net settleable solids in the hatchery effluent, measured in $\mathrm{ml} / \mathrm{L}$.
$<$ TSS COMP Average net total suspended solids, composite sample ( $6 \mathrm{x} /$ day ) of the hatchery effluent, measured in mg/L.
<TSS MAX Maximum daily net total suspended solids, composite sample ( $6 \mathrm{x} /$ day) of the hatchery effluent, measured in $\mathrm{mg} / \mathrm{L}$.
$<$ SS PA Maximum settleable solids discharge from the pollution abatement pond, measured in $\mathrm{ml} / \mathrm{L}$.
$<$ SS \% Removal of settleable solids within the pollution abatement pond from inlet to outlet, measured as a percent. No longer required under permit effective June 1, 2000.
<TSS PA Maximum total suspended solids effluent grab from the pollution abatement pond discharge, measured in $\mathrm{mg} / \mathrm{L}$.
$<$ TSS \% Removal of suspended solids within the pollution abatement pond from inlet to outlet, measured as a percent. No longer required under permit effective June 1, 2000.
<SS DD Settleable solids discharged during drawdown for fish release. One sample per pond drawdown, measured in $\mathrm{ml} / \mathrm{L}$.
$<$ TRC Total residual chlorine discharge after rearing vessel disinfection and after neutralization with sodium thiosulfate. One sample per disinfection, measured in ug/L.

In addition, at Similkameen Hatchery only, the following sampling was conducted at the request of Washington Department of Ecology, but is not required under NPDES permit:
<SS IW Settleable solids influent grab taken as wastes are pumped into the pollution abatement pond, measured in mg/L. No longer monitored as of January 2008.
$<$ TSS IW Total suspended solids influent grab as wastes are pumped into the pollution abatement pond, measured in $\mathrm{mg} / \mathrm{L}$. No longer monitored as of January 2008.

Steelhead Stock Assessment at Priest Rapids Dam, 2014-2015

## Priest Rapids Dam 2014-2015 Adult Upper Columbia River Steelhead Run-Cycle Stock Assessment Report

## Introduction

Upper Columbia River (UCR) steelhead stock assessment sampling at Priest Rapids Dam (PRD) is authorized through the Endangered Species Act (ESA) Section 10 Permit 1395 (NMFS 2003). Permit authorizations include interception and biological sampling of up to 10 percent of the UCR steelhead passing PRD to determine upriver population size, estimate hatchery to wild ratios, determine age-class contribution and evaluate the need for managing hatchery steelhead consistent with ESA recovery objectives, which include fully seeding spawning habitat with naturally produced UCR steelhead supplemented with artificially propagated enhancement steelhead (NMFS 2003).

## Stock Assessment

The 2014 steelhead sampling at Priest Rapids Dam began on 7 July and concluded 8 November. Sampling consisted of operating the Priest Rapids Off Ladder Fish Trap (OLAFT), located on the left-bank fishway at Priest Rapids Dam, 8 hours per day, up to three days per week, for a total of 53 sampling days. Steelhead were trapped, handled, and released in accordance with Section 2.1 and 2.2.1 of the National Marine Fisheries Service (NMFS) Biological Opinion for ESA Permit 1395 (NMFS 2003). The cumulative sample rate attained during 2014 totaled $17.3 \%$.

The Washington Department of Fish and Wildlife (WDFW) sampled 3,428 steelhead of the 2014/2015 run-cycle passing PRD, totaling 19,766 steelhead, for an overall sampling rate of $17.3 \%$. Of the 3,428 steelhead sampled, 2,262 ( $70.0 \%$ ) were hatchery origin and 1,166 (30.0\%) were wild origin. The estimated 2014-2015 run-cycle total wild steelhead return was 5,930 representing $207.2 \%$ of the 1986-2013 average and about $106.2 \%$ of the most recent 5-year average (Table 1).

Based on external marks and external and internal tags, 2,217 hatchery-origin steelhead were sampled at Priest Rapids Dam during the 2014 return cycle and included 30.4\% Wenatchee hatchery-origin steelhead and 47.1\% "above Wells Dam" hatchery-origin steelhead ${ }^{1}$ (Table 2), while $11.0 \%$ of the hatchery-origin steelhead sampled could not be assigned to a specific hatchery program. Ringold FH origin steelhead represented about $11.5 \%$ of the hatchery sample (Table 2).

[^50]Table 1. Priest Rapids Dam adult steelhead returns and stock composition, 1974-2013.

| Run-cycle ${ }^{1 /}$ | Hatchery | Wild | Wild percent | Total run |

| 2009-2013 average | 18,317 | 5,583 | 24.2 | 23,899 |

${ }^{1 /}$ A return cycle is the combined total of steelhead passing PRD from 1 June -30 November during year (x), plus steelhead passing PRD between 15 April and 31 May on year ( $\mathrm{x}+1$ ).

Table 2. Origin classification of steelhead sampled at Priest Rapids Dam, 7 July - 8 November 2014.

Reconciliation of saltwater age of wild and hatchery steelhead sampled at Priest Rapids Dam during 2014 was accomplished through scale analysis. Salt-age analysis of the 2014 UCR steelhead run-cycle provides an estimated hatchery-origin return dominated by 1salt and 2 -salt age composition of $34.1 \%$ and $65.8 \%$, respectively (Table 3). Naturalorigin steelhead salt ages were $31.1 \%$ and $68.8 \%$ for salt ages-1 and 2 , respectively. Three-salt age fish represented less than $0.1 \%$ of the combined hatchery/wild sample (Table 3).

Table 3. Salt-water age composition of 2014 - 2015 return cycle Upper Columbia River steelhead sampled at Priest Rapids Dam, corrected by scale age/origin determination.

| Salt-age | Origin |  |  |  | Combined |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Hatchery |  | Wild |  |  |  |
|  | $N$ | \% | $N$ | \% | $N$ | \% |
| 1-salt | 791 | 35.7 | 370 | 31.1 | 1161 | 34.1 |
| 2-salt | 1,422 | 64.3 | 817 | 68.8 | 2239 | 65.8 |
| 3-salt | 0 | 0.0 | 1 | 0.1 | 1 | >0.1 |
| 4-salt | 0 | 0.0 | 0 | 0.0 | 0 | 0.0 |
| Total | 2,213 |  | 1,188 |  | 3,401 |  |

Freshwater residency of naturally produced Upper Columbia River steelhead present in the 2014-2015 run-cycle were dominated by age-2 freshwater fish (78.9\%), and was only slightly lower than the 1986-2013 average of $74.2 \%$ (Table 4).

Table 4. 2014 return year freshwater age of wild Upper Columbia River steelhead sampled at Priest Rapids Dam during steelhead stock assessment activities, compared to July - November 1986-2013 average.

| Freshwater age | 2014-2015 run cycle |  | 1986-2013 proportion |  |
| :---: | :---: | :---: | :---: | :---: |
|  | $N$ | \% | $N$ | \% |

## Subject: 2016 Wenatchee Sockeye Mark/Recapture-Based Sockeye Escapement Estimates to Tributaries

## Introduction

In 2016, the Chelan County Public Utility District (District) estimated sockeye escapement to tributaries based on mark-recapture methodology. The purpose of this document is to report the spawning escapement estimates for the Little Wenatchee and White River subbasins. This information is used to track and/or estimate viable salmonid population parameters (VSP): abundance, productivity, spatial structure, and diversity (McElhaney et al. 2000).

## Methods

## Mark-Recapture Method:

Detection efficiencies of the in-stream arrays were calculated for the Little Wenatchee River and White River in 2016. The in-stream arrays include a series of upstream and downstream coils (Figure 1). Combined, these coils represented the upstream and downstream detection arrays, respectively. Overall detection efficiency $P_{\text {all }}$ of the arrays was calculated based on observed detection probabilities of individual arrays:

$$
P_{\text {all }}=1-\left(1-P_{\text {array } 1}\right)\left(1-P_{\text {array } 2}\right)
$$

where the probability of missing a fish on both the upstream $P_{\text {array1 }}$ and downstream $P_{\text {array2 }}$ arrays were combined for an overall efficiency $P_{\text {all }}$ (Connolly et al. 2008).

Adult sockeye salmon were tagged at adult fishways within the Columbia River and at Tumwater Dam. Additionally, adult returns that were PIT tagged as juveniles were used in the analyses. Total passage of adult sockeye salmon through Tumwater Dam was obtained from Columbia River Data Access in Real Time (DART 2016). Resulting tag files were queried in PTAGIS (2016), providing detection histories for each study fish.

Figure 1. Schematic of a PIT array configuration.

Resulting data from passage at Tumwater Dam, mark and recapture using PIT tags, and detection efficiency estimates can provide estimation of escapement to spawning tributaries. Assumptions include: (1) the study population is "closed," i.e., no individuals die or emigrate between the initial mark and subsequent recaptures; (2) tags are not lost and detections are correctly identified; (3) all individuals have the same probability of being detected, and (4) the number of recapture events are proportional to the total population. Lastly, it was assumed that PIT-tagging efforts at Tumwater have negligible influence on fish behavior and tagged individuals behave similarly to untagged individuals. The resulting escapement rate, adjusted for detection efficiency, was then applied to the total population as such:

$$
\text { Escapement }=\left(\frac{\left(\frac{O b s_{L W N}}{E f f_{L W N}}+\frac{O b s_{W T L}}{E f f_{W T L}}\right)}{P I T s_{T U M}}\right) \times \text { Counts }_{T U M}
$$

where the PIT tag detections ( $O b s$ ) at the Little Wenatchee ( $L W N$ ) and White River (WTL) were adjusted for detection efficiency (Eff), compared to the number released (PITs) at Tumwater Dam (TUM), and the resulting proportion was applied to the population observed (Counts) passing Tumwater Dam.

## Results

## Sockeye Salmon Mark-Recapture Method

Fishway enumeration at Tumwater Dam indicated that 73,697 adult sockeye salmon passed the facility during the 2016 migration, which was a sufficient return to open a recreational fishery in Lake Wenatchee for 2016. PIT tags were implanted in 790 fish at Tumwater and 630 fish were PIT-tagged before passing Tumwater; 130 fish were subsequently detected at the Little Wenatchee PIT tag array and 743 fish were subsequently detected at the White River PIT tag array (Table 1). Based on the recapture of PIT-tagged adult sockeye and assigned detection efficiency, total estimated escapement from Tumwater Dam to the Little Wenatchee River was 6,747 adult sockeye and 38,321 adult sockeye to the White River (Table 2).

## Executive Summary

Nine spawning populations of sockeye (Oncorhynchus nerka) salmon have been identified in Washington, including stocks in the Lake Wenatchee basin (SaSI 5800) (Washington Department of Fisheries et al. 1993). Lake Wenatchee sockeye are classified as an Evolutionary Significant Unit (ESU), and consists of sockeye salmon that spawn primarily in tributaries above Lake Wenatchee (the White River, Napeequa River, and Little Wenatchee Rivers). Since 1990, the Wenatchee Sockeye Program has released juveniles into Lake Wenatchee to supplement natural production of sockeye salmon in the basin. The program's broodstock are predominantly natural-origin sockeye adults returning to the Wenatchee River captured at Tumwater Dam (Rkm 52.0), where a netpen system is used to house both maturing adults and juveniles prior to release into Lake Wenatchee to over-winter.

Previous genetic studies have generally found a lack of concordance between population genetic relationships and their geographic distributions. These studies indicate that the nearest geographic neighbors of sockeye salmon populations are not necessarily the most genetically similar. Specifically for the Columbia River Basin, sockeye from Lake Wenatchee, Okanogan River, and Redfish Lake may be more closely related to a population from outside the Columbia River (depending on marker used) then to each other.

In this study we investigated the temporal and spatial genetic structure of Lake Wenatchee sockeye collections, without regard to sockeye populations outside of the Lake Wenatchee area. Our primary objective here was to determine if the Wenatchee Sockeye Program affected the natural Lake Wenatchee sockeye population. More specifically, we were tasked to determine if the genetic composition of Lake Wenatchee sockeye population had been altered by a supplementation program that was based on the artificial propagation of a small subset of that population. Using microsatellite DNA allele frequencies, we investigated population differentiation between temporally replicated collections of natural-origin Lake Wenatchee sockeye and program broodstock. We analyzed thirteen collections of Lake Wenatchee sockeye (Table 1), eight temporally replicated collections of natural-origin Lake Wenatchee sockeye ( $\mathrm{N}=786$ ) and five temporally replicated collections of Wenatchee Sockeye Program broodstock ( $\mathrm{N}=248$ ). Paired natural - broodstock collections were available from years 2000, 2001, 2004, 2006, and 2007.

## Conclusions

We observed that allele frequency distributions were consistent over time, irrespective of collection origin, resulting in small and statistically insignificant measures of genetic differentiation among collections. We interpreted these results to indicate no year-to-year differences in allele frequencies among natural-origin or broodstock collections. Furthermore, there were no observed difference between pre- and post-supplementation collections. Therefore, we accepted our null hypothesis that the allele frequencies of the broodstock collections equaled the allele frequencies of the natural collections, which
equaled the allele frequency of the donor population. Given the small differences in genetic composition among collections, the genetic model for estimating $\mathrm{N}_{\mathrm{e}}$ produced estimates with extremely large variances, preventing the observation of any trend in $\mathrm{N}_{\mathrm{e}}$.

## Introduction

A report titled "Conceptual Approach to Monitoring and Evaluating the Chelan County Public Utility District Hatchery Programs" was prepared July 2005 by Andrew Murdoch and Chuck Peven for the Chelan PUD Habitat Conservation Plan's Hatchery Committee. This report outlined 10 objectives to be applied to various species assessing the impact (positive or negative) of hatchery operations mitigating the operation of Rock Island Dam. This current study pertains only to Lake Wenatchee sockeye and objective 3:

> Determine if genetic diversity, population structure, and effective population size have changed in natural spawning populations as a result of the hatchery program. Additionally, determine if hatchery programs have caused changes in phenotypic characteristics of natural populations.

In order to evaluate cause and effect of hatchery supplementation, WDFW Molecular Genetics Lab surveyed genetic variation of Lake Wenatchee sockeye. The conceptual approach for this project follows that of a parallel study regarding the Wenatchee River spring Chinook supplementation program (Blankenship et al. 2007). We determined the genetic diversity present in the Lake Wenatchee sockeye population by analyzing temporally replicated collections spanning 1989-2007, which included collections from before and following the inception of the Wenatchee Sockeye Program. Documenting the genetic composition of the Lake Wenatchee sockeye population is necessary to assess the effect of the hatchery program on the Lake Wenatchee population. In addition, this work provides a genetic baseline for future projects requiring genetic data. See study objectives below for specific details about how this project addresses Murdoch and Peven (2005) objective 3.

## Lake Wenatchee Sockeye Salmon

Nine spawning populations of sockeye (Oncorhynchus nerka) salmon have been identified in Washington (Washington Department of Fisheries et al. 1993): 1) Baker

River, 2) Ozette Lake, 3) Lake Pleasant, 4) Quinault Lake, and 5) Okanogan River (classified as native stock); 6) Cedar River (classified as non-native stock); 7) Lake Wenatchee, classified as mixed stock); 8) Lake Washington/Lake Sammamish tributaries; and 9) Lake Washington beach spawners (classified as unknown origin). Chapman et al. (1995) listed four additional spawning aggregations of sockeye salmon that appear consistently in Columbia River tributaries: the Methow, Entiat, and Similkameen Rivers; and Icicle Creek in the Wenatchee River drainage.

Located in north central Washington, the Wenatchee River basin drains a portion of the eastern slope of the Cascade Mountains, including high mountainous regions of the Cascade crest. The headwater area of the Wenatchee River is Lake Wenatchee, a typical low productivity oligotrophic or ultra-oligotrophic sockeye salmon nursery lake (Allen and Meekin 1980, Mullan 1986, Chapman et al. 1995). Sockeye salmon bound for Lake Wenatchee enter the Columbia River in April and May and arrive at Lake Wenatchee in late July to early August (Chapman et al. 1995; Washington Department of Fisheries et al. 1993). The run timing of Lake Wenatchee sockeye salmon, classified as an Evolutionary Significant Unit (ESU), appears to have become earlier by 6-30 days during the past 70 years (Chapman et al. 1995; Quinn and Adams 1996). Additionally, scale pattern analysis suggests Wenatchee sockeye migrate past Bonneville Dam earlier than the sockeye bound for the Okanogan River (Fryer and Schwartzberg 1994). The Wenatchee population spawns from mid-September through October in the Little Wenatchee, White, and Napeequa Rivers above Lake Wenatchee (Washington Department of Fisheries et al. 1993), peaking in late September (Chapman et al. 1995). Limited beach spawning is believed to occur in Lake Wenatchee (L. Lavoy pers. com.; Mullan 1986), although Gangmark and Fulton (1952) reported two lakeshore seepage areas in Lake Wenatchee that were used by spawning sockeye salmon. Sockeye salmon fry enter Lake Wenatchee between March and May (Dawson et al. 1973), and typically rear in the lake for one year before leaving as smolts (Gustafson et al. 1997; Peven 1987).

Both the physical properties of the habitat and ecological/biological factors of the sockeye populations differ between the Lake Wenatchee ESU and the geographically
proximate Okanogan ESU. For example: 1) Different limnology is encountered by sockeye salmon in Lakes Wenatchee and Osoyoos; 2) Lake Wenatchee sockeye predominantly return at ages four and five (a near absence of 3-year-olds), where a large percentage of 3-year-olds return to the Okanogan population; and 3) the apparent one month separation in juvenile outmigration-timing between Okanogan- and Wenatcheeorigin fish (Gustafson et al. 1997 and references therein).

## Sockeye Artificial Propagation In Lake Wenatchee

The construction of Grand Coulee Dam completely blocked fish passage to the upper Columbia River, and $85 \%$ of sockeye salmon passing Rock Island Dam between 1935 and 1936 were estimated to be from natural stocks bound for areas up-river to Grand Coulee Dam (Mullan 1986; Washington Department of Fisheries et al. 1938). To compensate for loss of habitat resulting from Grand Coulee Dam, the federal government initiated the Grand Coulee Fish-Maintenance Project (GCFMP) in 1939 to maintain fish runs in the Columbia River above Rock Island Dam. Between 1939 and 1943, all sockeye salmon entering the mid-Columbia River were trapped at Rock Island Dam, and over 32,000 mixed Lake Wenatchee, Okanogan River, and Arrow Lake adult sockeye salmon were released into Lake Wenatchee (Gustafson et al. 1997 Appendix Table D-2). In addition to adult relocation, between 1941 and 1969 over 52.8 million fry descended from original spawners collected at Rock Island and Bonneville Dams, were released into Lake Wenatchee (Gustafson et al. 1997 Appendix Table D-2).

No releases of artificially-reared sockeye salmon occurred in the Wenatchee watershed during the years 1970 to 1989 (Gustafson et al. 1997 Appendix Table D-2). Since 1990, the Wenatchee Sockeye Program has released juveniles into Lake Wenatchee to supplement natural production of sockeye salmon in the basin. Sockeye adults returning to the Wenatchee River are captured at Tumwater Dam (Rkm 52.0) and transferred to Lake Wenatchee net pens until mature. The Wenatchee Sockeye Program goals are 260 adults with an equal sex ratio, $<10 \%$ hatchery-origin returns (identified by coded wire tags), and the adults removed for broodstock account for $<10 \%$ of the run size. Fish are spawned at Lake Wenatchee and their gametes are taken to Rock Island Fish Hatchery

Complex (i.e., Eastbank) for fertilization and incubation. Fry are returned to the Lake Wenatchee net -pens after they are large enough to be coded wire tagged, and are housed in the pens until fall (one year after spawning), when they are liberated into the lake to over-winter. For brood years 1991 - 2004 an average of 218,683 (std. dev. $=71,090$ ) pen-reared Lake Wenatchee-origin juvenile sockeye salmon have been released yearly into Lake Wenatchee.

## Previous Genetic Studies

Protein (allozyme) variation - Surveying genetic variation at 12 allozyme loci, Utter et al. (1984) reported moderate population structure among 16 sockeye collections from southeast Alaska through the Columbia River Basin, including Okanogan and Wenatchee stocks, with an apparent genetic association between upper Fraser River and Columbia River sockeye salmon. Winans et al. (1996) surveyed variation at 55 allozyme loci for 25 sockeye salmon and two kokanee collections from 21 sites in Washington, Idaho, and British Columbia, and reported the lowest level of allozyme variability of any species of Pacific salmon and a highest level of inter-population differentiation. Furthermore, these authors reported that there was no clear relationship between geographic and genetic differentiation among the populations within there study. Other studies corroborate the results of Winans et al. (1996), finding a lack of discernible geographic patterning for sockeye salmon populations in British Columbia, Alaska, and Kamchatka (Varnavskaya et al. 1994, Wood et al. 1994, Wood 1995). These studies indicate that the nearest geographic neighbors of sockeye salmon populations are not necessarily the most genetically similar, which contrasts with the other Pacific salmon species that exhibit concordance between geographic and genetic differentiation (Utter et al. 1989, Winans et al. 1994, Shaklee et al. 1991). As part of the comprehensive status review of west coast sockeye salmon (Gustafson et al. 1997), NMFS biologists collected new allozyme genetic information for 17 sockeye salmon populations and one kokanee population in Washington and combined these data for analysis with the existing Pacific Northwest sockeye salmon and kokanee data from Winans et al. (1996). Results of the updated study were consistent with Winans et al. (1996), with no clear concordance between geographic and genetic distances. Sockeye salmon from Lake Wenatchee, Redfish Lake,

Ozette Lake, and Lake Pleasant are very distinct from other collections in the study, and Columbia River populations were not necessarily most closely related to each other. Gustafson et al. (1997) also examined between-year variability within a collection location and found low levels of statistical significance among the five Lake Wenatchee collections included in the study (For 10 pair-wise comparisons using sum-G test, five were statistically significant). Lake Wenatchee brood year 1987 accounted for three of the significant comparisons, which were driven by unusually high frequencies of two allozyme alleles (ALAT*95 and ALAT*108) (Winans et al. 1996). Nevertheless, Gustafson et al. (1997) conclude that, in general, temporal variation at a locale was considerably less than between-locale variation.

Nucleic acid variation - Beacham et al. (1995) reported levels of variation in nuclear DNA of $O$. nerka using minisatellite probes. They analyzed 10 collections, including a sample from Lake Wenatchee. Cluster analysis showed the Lake Wenatchee sample was different from all the other collections, including those from the Columbia River. Using a similar molecular technique, Thorgaard et al. (1995) examined the use of multi-locus DNA fingerprinting (i.e., banding patterns) to discriminate among 14 sockeye salmon and kokanee populations. Dendrograms based on analysis of banding patterns produced different genetic affinity groups depending on the probes used. While none of the five DNA probes showed a close relationship between Lake Wenatchee and Okanogan River sockeye salmon, if information from all probes were combined, O. nerka from Redfish Lake, Wenatchee, and Okanogan were separate from kokanee of Oregon and Idaho and a sockeye salmon sample from the mid-Fraser River.

## Study Objective

We documented temporal variation in genetic diversity (i.e., heterozygosity and allelic diversity), and investigated population differentiation between temporally replicated collections of natural-origin Lake Wenatchee sockeye and program broodstock, using microsatellite DNA allele frequencies. Temporally replicated collections from the same location can also be used to estimate effective population size $\left(\mathrm{N}_{\mathrm{e}}\right)$. If populations are "ideal", the census size of a population is equal to the "genetic size" of the population.

Yet, numerous factors lower the "genetic size" below census, such as, non-equal sex ratios, changes in population size, and variance in the numbers of offspring produced from parent pairs. $\mathrm{N}_{\mathrm{e}}$ is thought to be between 0.10 and 0.33 of the estimated census size (Bartley et al. 1992; RS Waples pers. comm.), although numerous observations differ from this general rule. $\mathrm{N}_{\mathrm{e}}$ can be calculated directly from demographic data, or inferred from observed differences in genetic variance over time. Essentially, when calculated from genetic data, $\mathrm{N}_{\mathrm{e}}$ is the estimated size of an "ideal" population that accounts for the genetic diversity changes observed, irrespective of abundance.

We will address the hypotheses associated with Objective 3 in Murdock and Peven (2005) using the following four specific tasks:

Task 1 - Document the observed genetic diversity.
Task 2 - Test for population differentiation among Lake Wenatchee collections and the associated supplementation program.

Task 2 was designed to address two hypotheses listed as part of Objective 3 in Murdoch and Peven (2005):

- Ho: Allele frequency Hatchery $=$ Allele frequency ${ }_{\text {Naturally produced }}=$ Allele frequency Donor pop .
- Ho: Genetic distance between subpopulations Year $x=$ Genetic distance between subpopulations Year y Murdoch and Peven (2005) proposed these two hypotheses to help evaluate supplementation programs through a "Conceptual Process" (Figure 5 in Murdoch and Peven 2005). There are two components to the first hypothesis, which must be considered separately for Lake Wenatchee sockeye. The first component involves comparisons between natural-origin populations from Lake Wenatchee to determine if there have been changes in allele frequencies through time starting with the donor population. Documenting a change does not necessarily indicate that the supplementation program has directly affected the natural-origin fish, as additional tests would be necessary to support that hypothesis. The intent of the second component is to determine if the hatchery produced populations have the same genetic composition as the naturally produced populations.

Task 3 - Calculate $\mathrm{N}_{\mathrm{e}}$ using the temporal method for multiple samples from the same location to document trend.

Task 4 - Compare $\mathrm{N}_{\mathrm{e}}$ estimates with trend in census size for Lake Wenatchee sockeye.

## Methods and Materials

## Sampling

Thirteen collections of Lake Wenatchee sockeye were analyzed, eight temporally replicated collections of natural Lake Wenatchee sockeye ( $\mathrm{N}=786$ ) and five temporally replicated collections of Wenatchee Sockeye Program broodstock (N=248) (Table 1). Paired natural - broodstock collections were available from years 2000, 2001, 2004, 2006, and 2007 (Table 1). All collections were made at Tumwater Dam on the Wenatchee River. Note that collections classified as broodstock were predominantly natural-origin sockeye. A majority of the genetic samples were from dried scales. The tissue collections from 2006 and 2007 were fin clips stored immediately in ethanol after collection. DNA was extracted from stored tissue using Nucleospin 96 Tissue following the manufacturer's standard protocol (Macherey-Nagel, Easton, PA, U.S.A.).

## Laboratory Analysis

Polymerase chain reaction (PCR) amplification was performed using 17 fluorescently end-labeled microsatellite marker loci, One 2 (Scribner et al 1996) One 100, 101, 102, 105, 108, 110, 114, and 115 (Olsen et al. 2000), Omm 1130, 1135, 1139, 1142, 1070, and 1085 (Rexroad et al. 2001), Ots 3M (Banks et al. 1999) and Ots 103 (Small et al. 1998). PCR reaction volumes were $10 \mu \mathrm{~L}$, with the reaction variables being $2 \mu \mathrm{~L} 5 \mathrm{x}$ PCR buffer (Promega), $0.6 \mu \mathrm{~L} \mathrm{MgCl}_{2}(1.5 \mathrm{mM})$ (Promega), $0.2 \mu \mathrm{~L} 10 \mathrm{mM} \mathrm{dNTP}$ mix (Promega), and $0.1 \mu \mathrm{~L}$ Go Taq DNA polymerase (Promega). Loci were amplified as part of multiplexed sets, so primer molarities and annealing temperatures varied. Multiplex one had an annealing temperature of $55^{\circ} \mathrm{C}$, and used 0.09 Molar (M) One 108, 0.06 M One 110, and 0.11 M One 100. Multiplex two had an annealing temperature of $53^{\circ} \mathrm{C}$, and used 0.08 M One 102, 0.1 M One 114, and 0.05 M One 115. Multiplex three had an annealing temperature of $55^{\circ} \mathrm{C}$, and used 0.08 M One 105 and 0.07 M Ots 103. Multiplex four had
an annealing temperature of $53^{\circ} \mathrm{C}$, and used 0.09 M Omm 1135 and 0.08 M Omm 1139 . Multiplex five had an annealing temperature of $60^{\circ} \mathrm{C}$, and used $0.2 \mathrm{M} \mathrm{Omm} \mathrm{1085}$, Omm 1070, and 0.05 M Ots 3 M . Multiplex six had an annealing temperature of $48^{\circ} \mathrm{C}$, and used 0.06 M One 2, 0.08 M Omm 1142 , and $0.08 \mathrm{M} \mathrm{Omm} \mathrm{1130}$.One 101 was run in isolation with a primer molarity of 0.06 . Thermal cycling was conducted on either PTC200 (MJ Research) or GeneAmp 9700 thermal cyclers as follows: $94^{\circ} \mathrm{C}(2 \mathrm{~min}) ; 30$ cycles of $94^{\circ} \mathrm{C}$ for 15 sec ., 30 sec . annealing, and $72^{\circ} \mathrm{C}$ for 1 min .; a final $72^{\circ} \mathrm{C}$ extension and then a $10^{\circ} \mathrm{C}$ hold. PCR products were visualized by denaturing polyacrylamide gel electrophoresis on an ABI 3730 automated capillary analyzer (Applied Biosystems). Fragment analysis was completed using GeneMapper 3.7 (Applied Biosystems).

## Genetic data analysis

Assessing within collection genetic diversity - Heterozygosity measurements were reported using Nei's (1987) unbiased gene diversity formula (i.e., expected heterozygosity) and Hedrick's (1983) formula for observed heterozygosity. Both tests were implemented using the microsatellite toolkit (Park 2001). For each locus and collection FSTAT version 2.9.3.2 (Goudet 1995) was used to assess Hardy-Weinberg equilibrium, where deviations from the neutral expectation of random associations among alleles were calculated using a randomization procedure. Alleles were randomized among individuals within collections (4160 randomizations for this dataset) and the FIS (Weir and Cockerham 1984) calculated for the randomized datasets were compared to the observed $\mathrm{F}_{\text {IS }}$ to obtain an unbiased estimation of the probability that the null hypothesis was true. The 5\% nominal level of statistical significance was adjusted for multiple tests (Rice 1989). Genotypic linkage disequilibrium was calculated following Weir (1979) using GENETIX version 4.05 (Belkhir et al. 1996). Statistical significance of linkage disequilibrium results was assessed using a permutation procedure implemented in GENETIX for each locus by locus combination within each collection.

Assessing among collection genetic differentiation - The temporal stability of allele frequencies was assessed by the randomization chi-square test implemented in FSTAT version 2.9.3.2 (Goudet 1995). Multi-locus genotypes were randomized between
collections. The G-statistic for observed data was compared to G-statistic distributions from randomized datasets (i.e., null distribution of no differentiation between collections). Population differentiation was also investigated using pairwise estimates of
 variance (Weir and Cockerham, 1984), were calculated using GENETIX version 4.05 (Belkhir et al.1996). $\mathrm{F}_{\text {ST }}$ was used to quantify population structure, the deviation from statistical expectations (i.e., excess homozygosity) due to non-random mating between populations. To determine if the observed $\mathrm{F}_{\text {ST }}$ estimate was consistent with statistically expectations of no population structure, a permutation test was implemented in GENETIX (1000 permutations).

Effective population size ( $\mathbf{N}_{\mathbf{e}}$ ) - Estimates of the effective population size were obtained using a multi-collection temporal method (Waples 1990a). The temporal method assumes that cohorts are used, but we did not decompose the collection year samples into their respective cohorts using age data. Therefore, $\mathrm{N}_{\mathrm{e}}$ estimates that pertain to individual year classes of breeders are not valid; however the harmonic mean over all samples will estimate an $\mathrm{N}_{\mathrm{e}}$ that pertains to the time period from which the collections are derived. Comparing samples from years $i$ and $j$, Waples’ (1990a) temporal method estimates the effective number of breeders ( $\hat{\mathrm{N}}_{\mathrm{b}(\mathrm{i}, \mathrm{j})}$ ) according to:

$$
\hat{\mathrm{N}}_{\mathrm{b}(\mathrm{i}, \mathrm{j})}=\frac{\mathrm{b}}{2\left(\hat{\mathrm{~F}}-1 / \widetilde{\mathrm{S}}_{\mathrm{i}, \mathrm{j}}\right)}
$$

The standardized variance in allele frequency ( $\hat{\mathrm{F}}$ ) is calculated according to Pollack (1983). The parameter b is calculated analytically from age structure information and the number of years between samples (Tajima 1992). The age-at-maturity information required to calculate $b$ was obtained from ecological data (Hillman et al. 2007). The harmonic mean of sample sizes from years $i$ and $j$ is $\tilde{\mathrm{S}}_{\mathrm{i}, \mathrm{j}}$. The harmonic mean over all pairwise estimates of $\hat{\mathrm{N}}_{\mathrm{b}(\mathrm{i}, \mathrm{j})}$ is $\tilde{\mathrm{N}}_{\mathrm{b}}$. SALMONNb (Waples et al. 2007) was used to calculate $\tilde{\mathrm{N}}_{\mathrm{b}}$.

## Results and Discussion

In this section we combine our presentation and interpretations of the genetic analyses. Additionally, this section is organized based on the task list presented in the study plan.

Task 1 - Document the observed genetic diversity.

Substantial genetic diversity was observed over all Lake Wenatchee sockeye collections analyzed (Table 1), with heterozygosity estimates over all loci having a mean of 0.79 . Genetic diversity was consistent with expected Hardy-Weinberg random mating genotypic proportions for all collections. The FIS observed for each collection was not statistically significant given the distribution of $F_{\text {IS }}$ generated using a randomization procedure. Additionally, there were no statistically significant associations observed between alleles across loci (i.e., linkage equilibrium) (data not shown). We concluded from these results that the genetic data from each collection was consistent with statistical expectations for random association of alleles within and between loci. In other words, each collection represents samples from a single gene pool (i.e., populations), and the genetic diversity observed has no detectable technical artifacts or evidence of natural selection.

Task 2 - Test for differentiation among Lake Wenatchee collections and the associated supplementation program.

We explicitly tested the hypothesis of no significant differentiation within natural-origin or broodstock collections from Lake Wenatchee using a randomization chi-square test. The null hypothesis for these tests was that the allele frequencies from two different populations were drawn from the same underlying distribution. We show the results for the pairwise comparisons among eight temporally replicated natural-origin collections from Lake Wenatchee (28 pairwise tests), and report all tests were non-significant (Table 2A). Similarly, for five temporally replicated broodstock collections, 10 of 10 pairwise tests were non-significant (Table 2B). We also tested if natural-origin and broodstock
collections were differentiated from each other over time, and report that 40 of 40 tests were non-significant (Table 2C). The nominal level of statistical significance ( $\alpha=0.05$ ) was adjusted for multiple comparisons using strict Bonferroni correction (Rice 1989). Yet, there are perhaps slight differences between paired natural-broodstock collections. Note that the p-values for comparisons regarding 2006 and 2007 paired collections are lower than for comparisons regarding 2000, 2001, and 2004. The small sample sizes for broodstock collections in 2006 and 2007 may not have been random samples from the Lake Wenatchee sockeye population.

Given the consistencies observed for allele frequency distributions over time, metrics of population structure were expected to be small. This was the case, as the estimated $\mathrm{F}_{\text {ST }}$ over all thirteen collections was 0.0003 . This observed value fell within the distribution of $\mathrm{F}_{S T}$ values expected if there were no population structure present (permutation test pvalue 0.12 ). Analysis of the paired natural-broodstock collections corroborated this result. Pairwise estimates of $\mathrm{F}_{\text {ST }}$ were 0.000 for years 2000, 2001, 2004, and 2007, and 0.002 for 2006. All five estimates were non-significant. Essentially, all 13 sockeye collections could be considered samples from the same population. Given these results, it is valid to combine all collections for statistical analysis. Therefore, we did not calculate genetic distances among any collections, as it is inappropriate to estimate distances that are effectively zero.

## Conclusions

We interpret these data to indicate that there appears to be no significant year-to-year differences in allele frequencies among natural-origin or broodstock collections, nor are there observed differences between collections pre- and post-supplementation. As a result, we accept the null hypothesis that the allele frequencies of the broodstock collections equal the allele frequencies of the natural collections, which equals the allele frequency of the donor population. Furthermore, the observed genetic variance that can be attributed to among collection differences was negligible.

Task 3 - Calculate $\mathrm{N}_{\mathrm{e}}$ using the temporal method for multiple samples from the same location to document trend.

The fundamental parameter for inferring $\mathrm{N}_{\mathrm{e}}$ using genetic data is the standardized variance in allele frequency ( $\hat{\mathrm{F}}$ ) (Pollack 1983). Methods estimate $\mathrm{N}_{\mathrm{e}}$ from observed changes in $\hat{F}$ over temporally replicated collections from the same location. Yet, as previously shown, there were no statistically significant differences detected in allele frequencies. The underlying model for estimating $\mathrm{N}_{\mathrm{e}}$ produced estimates with extremely large variances, given small temporal differences in $\hat{F}$, which rendered any trend in $N_{e}$ unobservable. Table 3 shows $\mathrm{N}_{\mathrm{e}}$ estimates calculated using temporally replicated natural collections.

Task 4 - Compare $\mathrm{N}_{\mathrm{e}}$ estimates with trend in census size for Lake Wenatchee sockeye.

See Task 3

## Acknowledgements

We would like to thank Jeff Fryer (CRITFC) for providing critical collections of naturalorigin sockeye from Lake Wenatchee. We would like to thank Norm Switzler for collection curation and Ken Warheit and Denise Hawkins for helpful comments regarding this project. This project was funded by Chelan County PUD and the Washington State General Fund.

Table 3 Estimation of $\mathrm{N}_{\mathrm{e}}$ for temporally replicated natural-original sockeye collections. Above the diagonal are pairwise estimates of $\mathrm{N}_{\mathrm{e}}$, where negative values mean sampling variance can account for genetic variance observed (i.e., genetic drift unnecessary).

Below the diagonal are variances for pairwise estimates of $\mathrm{N}_{\mathrm{e}}$. Absent variance values (denoted by - ) were too large for SalmonNb to display.

## Wenatchee Spring Chinook Redd Estimates, 2016

# Spring Chinook Redd Estimates - 2016 

Upper Wenatchee

Kevin See

December 22, 2016

## Goals

Redd counts are an established method to provide an index of adult spawners (Gallagher et al. 2007). In the Wenatchee subbasin, spawning reaches are surveyed weekly during the spring Chinook spawning season (Jul 25, 2016-Oct 03, 2016). The goals of this work are to:

- Estimate the true number of redds in each spawning reach with uncertainty.
- Summarize the number of redds at the tributary and population scale.

## Methods

## Data

Data were collected on the number of new redds during each survey (usually conducted about every week during the spawning season). Covariates such as surveyor experience, mean thalweg CV, and redd density (observed redds / km) were also collected on the reach scale to make predictions of surveyor error.

## Surveyor Error

From the results of a previous study on spring Chinook, similar to the one outlined in Murdoch et al. (2014) for steelhead, we had a model that predicted surveyor net error (ratio of identified redds to true redds) based on covariates such as the surveyor's total experience with spawning ground surveys, the mean thalweg CV, and the observed redd density (redds/km). This model suggests that increasing experience and observed redd density lead to higher net error, while increasing the stream complexity (mean thalweg CV) leads to lower net error.

Because the net error model is a linear model, and therefore not constrained to be between 0 and 1 (less than 1 implies an underestimate of the number of redds, while net error greater than 1 implies an overestimate due to false identifications), we examined the values of the predictive covariates and compared them to the values used to fit the net error model. Several values were outside the range of the model dataset (See Figure 1). However,
using those more extreme values did not result in absurd predictions of observer error, so we did not alter or constrain them.

Values of the covariates for the net surveyor error model, colored by stream. Dashed lines depict the range of values from the data set used to develop the net error model.

## Total Redds

Estimates of total redds were made for each reach using the Gaussian area under the curve (GAUC) model described in Millar et al. (2012). The GAUC model was developed with spawner counts in mind. As it is usually infeasible to mark every individual spawner, only total spawner counts can be used, and an estimate of average stream life must be utilized to translate total spawner days to total unique spawners. However, in adapting this for redd surveys, individual redds can be marked, and therefore we fit the GAUC model to new redds only. The equivalent of stream life thus becomes the interval between surveys. However, this year surveys were unable to be conducted during several weeks coinciding with peak spawning in the Chiwawa. Therefore, to fit the GAUC model, we used survey number instead of Julian day, and set the survey interval to one. We fit these models to reach-scale data, which did pose several challenges for a few reaches. We did not make

GAUC estimates for reaches that had fewer than 2 observed redds, or less than 3 weeks with at least one new redd observed.

When summing GAUC estimates at the reach-scale to obtain estimates at the stream scale, an attempt was made to incorporate the fact that the reaches within a stream are not independent. Estimates of correlation between the reaches within a stream were made based on weekly observed redds. This method may not be perfect, since spawners may use certain reaches preferentially at different times in the season, but it may be the best we can do. Because correlations are often quite high between reaches, this is a better alternative than to naively assume the standard errors between reaches are independent of one another. These estimates of correlation were combined with GAUC estimates of standard error for each reach to calculate a covariance matrix for the reaches within each stream, which was used when summing estimates of total redds to estimate the standard error at the stream-scale. Failure to incorporate the correlations between reaches would result in an underestimate of standard error at the stream scales. Different streams (and therefore reaches in different streams) were assumed to be independent.

## Results

## Surveyor Error

Predictions of net error are shown in Figure 2. Most predictions were less than one, implying some redds may have been missed. A few surveys had predictions of net error greater than one, implying some redds identified by surveyors were false redds.

Boxplots showing predicted net error by stream. Dashed line shows no error.

## Total Redds

Redds were estimated at the reach scale using the GAUC method whenever possible, and simply dividing the total number of observed redds by the predicted net error when not. For a few small tributary reaches, no estimates of observer error were made and instead the small number of observed redds was assumed to be observed without error. The estimates at the reach scale are displayed in Table 1. The curves that were fit in the GAUC process are shown in Figure 3. The results are summarized at the stream and population scale in Table 2.

## Executive Summary

The main objective of this study was to determine the potential impacts of the Chiwawa River Supplementation Program on natural spring Chinook in the upper Wenatchee system. We did this by investigating population differentiation between temporally replicated Chiwawa River natural and hatchery samples from the Wenatchee River watershed using microsatellite DNA allele frequencies and the statistical assignment of individual fish to specific populations. Additionally, to assess the genetic effect of the hatchery program, we investigated the relationship between census and effective population sizes using collections obtained before and after the supplementation program. In this summary, we briefly describe the salient results contained within this report; however, each "Task" within the Results/Discussion section below contains extended coverage for each topic along with an expanded interpretation of each result.

Overall, we observed substantial genetic diversity within collections, with heterozygosities equal to roughly $80 \%$, over thirteen microsatellite markers. Microsatellite allele frequencies among temporally replicated collections from the same population (i.e., location) were variable, resulting in significant genetic differentiation among these collections. However, these difference are likely the result of salmon life history in this area, as four-year-old Chinook comprise a majority of returns each year. That is, the genetic tests are detecting the differences of contributing parents from each cohort, rather than a hatchery effect.

## Analysis of Chiwawa River Collections

To assess the multiple competing hypotheses regarding population differentiation within and among Chiwawa River collections, we found it necessary to organized the Chiwawa genetic data into three data sets: (1) fish origin (hatchery versus natural), (2) spawning location (hatchery broodstock versus in-river (natural) spawners), and (3) four "treatment" groups (1. hatchery-origin hatchery broodstock, 2. hatchery-origin natural spawner, 3. natural-origin natural spawner, and 4. natural-origin hatchery broodstock). We conducted separate analyses using each of the three data sets, with each analysis
touching on some aspect of the components necessary to move through the Conceptual Process outlined by Murdoch and Peven (2005).

Origin Dataset - We report that allele frequencies within and between natural- and hatchery-origin collections are significantly different, but there does not appear to be a robust signal indicating that the recent natural-origin collections have diverged greatly from the pre- or early post-supplementation collections. Genetic drift will occur in all populations, but does not appear to be a major factor affecting allele frequencies within the Chiwawa collections.

Spawning Location Dataset - There are significant allele frequency differences within and between hatchery broodstock and natural spawner collections. However, in recent years the allele frequency differences between the hatchery broodstock and natural spawner collections have declined. Furthermore, based on linkage disequilibrium, there is a genetic signal that is consistent with increasing homogenization of allele frequencies within hatchery broodstock collections, but a similar homogenization within the natural spawner collection is not apparent. These data suggest that there exists consistent year-to-year variation in allele frequencies among hatchery and natural spawning collections, but there is a trend toward homogenization of the allele frequencies of the natural- and hatchery-origin fish that compose the hatchery broodstock.

Four Treatment dataset - Although there are signals of allelic differentiation among Chiwawa River collections, there are no robust signs that these collections are substantially different from each other. We used two different analyses to measure the degree of genetic variation that exists among individuals and collections within the Chiwawa River. First, we conducted a principal component analysis using all Chiwawa samples with complete genotypes (i.e., no missing alleles from any locus). Although the first two principal component axes account for only $10.5 \%$ of the total molecular variance, a substantially greater portion of that variance is among individual fish, regardless of their identity, rather than among hatchery and natural collections. The
variances in principal component scores among individuals are 11 and 13 times greater than the variance in scores among collections.

Secondly, using an Analysis of Molecular Variance (AMOVA), we were able to determine how best to group populations, with "best" being defined as that grouping that accounts for the greatest proportion of among group (i.e., population) variance. Furthermore, by partitioning molecular variance into different hierarchical components, we are able to determine what level accounts for the majority of the molecular variance. The AMOVA results clearly show that nearly all molecular variation, no matter how the data are organized, resides within a collection. The percentage of total molecular variance occurring within collections ranged from $99.68 \%$ to $99.74 \%$. These results indicate that the significant differences among collections of Chiwawa fish account for less than one percent of the total molecular variance, and these differences cannot be attributed to fish origin or spawning location.

## Effective Population Size ( $N_{e}$ )

The contemporary estimate of $\mathrm{N}_{\mathrm{e}}$ calculated using genetic data combined for Chiwawa natural-origin spawners (NOS) and hatchery-origin spawners (HOS) Chinook is $\mathrm{N}_{\mathrm{e}}=386.8$, which is slightly larger than the pre-hatchery $\mathrm{N}_{\mathrm{e}}$ we estimated using demographic data from 1989 - 1992. Additionally, the $\mathrm{N}_{\mathrm{e}} / \mathrm{N}$ ratio calculated using 386.8 for $\mathrm{N}_{\mathrm{e}}$ and the arithmetic mean yearly census of NOS and HOS Chinook from 1989 2005 for N is 0.40 . These results suggest the $\mathrm{N}_{\mathrm{e}}$ has not declined during the period of Chiwawa Hatchery Supplementation Program operation.

## Analysis Of Upper Wenatchee Tributary Collections

We compared genetic data for spring Chinook collected from the major spawning aggregates of the Wenatchee River. We observed significant differences in allele frequencies among temporally replicated collections within populations, and among populations within the upper Wenatchee. However, these differences account for a very small portion of the overall molecular variance, and these populations overall are very similar to each other. Of all the populations within the Wenatchee River, the White River
appears to be the most distinct. Yet, this distinction is more a matter of detail than of large significance, as the median $\mathrm{F}_{\text {ST }}$ between White River collections and all other collections (except the Little Wenatchee collection; see Results/Discussion) is less than $1.5 \%$ among population variance. We consider the implications of these results in the Conclusion section that follows the Results/Discussion section. Additionally, there is no evidence that the Chiwawa River Supplementation Program has changed the allele frequencies in the Nason Creek and White River populations, despite the presence of hatchery-origin fish in both these systems.

## Introduction

Murdoch and Peven (2005) outlined 10 objectives to assess the impact (positive or negative) of hatchery operations mitigating the operation of Rock Island Dam. Two objectives relate to monitoring the genetic integrity of populations:

Objective 3: Determine if genetic diversity, population structure, and effective population size have changed in natural spawning populations as a result of the hatchery program. Additionally, determine if hatchery programs have caused changes in phenotypic characteristics of natural populations.

Objective 5: Determine if the stray rate of hatchery fish is below the acceptable levels to maintain genetic variation between stocks.

This study addresses Objective 3 (above), and documents analyses and results WDFW completed for populations of spring Chinook (Oncorhynchus tshawytscha) in the Wenatchee River watershed. This study was not intended to specifically address Objective 5 (above); however, genetic data provide results relevant to Objective 5. The critical component of Objective 3 is to determine if hatchery supplementation has effected change. Furthermore, change in this context means altering census size and/or genetic marker allele frequencies; we did not attempt to measure changes in fitness. Perhaps a more meaningful rewording of Objective 3 is, "Did the hatchery supplementation program succeed at increasing the census size of a target population while leaving genetic integrity intact?" In order to evaluate cause and effect of hatchery supplementation, we surveyed and compared genetic variation in samples collected before and after potential effects from the Chiwawa Hatchery Supplementation Program. Samples were acquired from the primary spawning aggregates in the upper Wenatchee River watershed: Nason Creek, Little Wenatchee River, White River, and Chiwawa River. Hatchery samples were acquired from programs that could potentially affect genetic composition of Wenatchee stocks, the integrated Chiwawa River stock (local stock), Leavenworth National Fish Hatchery spring Chinook (Carson Stock - non local), and Entiat NFH (Carson Stock - non local). Additionally, the genetic markers used were the Genetic Analysis of Pacific Salmonids (GAPS) (Seeb et al. in review) standardized
microsatellites, so all data from the Wenatchee study will be available for inclusion in the GAPS Chinook coastwide microsatellite baseline.

## History of Artificial Propagation

Artificial propagation in the upper Columbia River began in 1899 when hatcheries were constructed on the Wenatchee and Methow rivers (Mullan 1987). These initial operations were small, with the Tumwater Hatchery on the Wenatchee River releasing several hundred thousand fry, and the Methow River hatchery producing few Chinook salmon before it was closed in 1913 (Craig and Suomela 1941, Nelson and Bodle 1990). The Leavenworth State Hatchery operated in the Wenatchee River Basin between 1913 and 1931 using eggs from non-native stocks (Willamette River spring-run and lower Columbia Chinook hatchery fall-run). These early attempts at hatchery production were largely unsuccessful for spring-run Chinook (WDF 1934). Between 1931 and 1939, no Chinook salmon hatcheries were in operation above Rock Island Dam (Rkm 730).

In 1938, the last salmon was allowed to pass upstream through the uncompleted Grand Coulee Dam (Rkm 959). To mitigate the loss of habitat, adult Chinook salmon were trapped, under the auspices of the Grand Coulee Fish Maintenance Project (GCFMP), at Rock Island Dam beginning in May 1939, and relocated into three of the remaining accessible tributaries to the upper Columbia River: the Wenatchee, Entiat, and Methow Rivers. GCFMP transfers continued through the autumn of 1943. Spring- and summer/fall-run fish were differentiated at Rock Island Dam based on a 9 July cutoff date for Chinook arrivals at Rock Island Dam (Fish and Hanavan 1948). Spring-run adults collected at Rock Island Dam (pre 9 July fish) were either transported to Nason Creek on the Wenatchee River to spawn naturally (1939-43), or to the newly constructed Leavenworth NFH (1940) for holding and subsequent spawning (1940-43). Eggs were incubated on site or transferred to the Entiat NFH (1941) and Winthrop NFH (1941). In 1944 spring-run adults were allowed to freely pass Rock Island Dam. The GCFMP did not differentiate among late-run stocks (post 9 July fish) passing Rock Island Dam. Laterun offspring reared at the Leavenworth NFH, Entiat NFH, and Winthrop NFHs were an
amalgamation of summer and fall upper Columbia River populations (Fish and Hanavan 1948). Late-run fish were transplanted into the upper and lower Wenatchee, Methow, and Entiat Rivers.

After 1943, the Winthrop NFH continued to use local spring-run Chinook for hatchery production, while the other NFHs largely focused on summer-run Chinook salmon. Renewed emphasis on spring run production in the mid-1970s saw the inclusion of local and non-local eggs (Carson NFH stock, Klickitat River stock, and Cowlitz River stock) to the NFHs. In the early 1980s, imports of non-native eggs were reduced significantly, and thereafter the Leavenworth, Entiat, and Winthrop NFHs have relied on adults returning to their facilities for their egg needs (Chapman et al. 1995). Regarding late-run Chinook, due to the variety of methods employed to collect broodstock at dams, hatcheries, or the result of juvenile introductions into various areas, Chinook populations and runs (i.e., summer and fall) have been mixed considerably in the upper Columbia system over the past five decades (reviewed in Chapman et al. 1994).

Washington Department of Fish and Wildlife (WDFW) operates two facilities producing spring-run Chinook, the Methow Fish Hatchery (MFH) owned by Douglas County PUD that began operation in 1992 and Eastbank Fish Hatchery (EFH) owned by Chelan County PUD that began operation in 1989. Both programs were designed to implement supplementation (supportive breeding) programs for naturally spawning populations on the Methow and Wenatchee Rivers, respectively (Chapman et al. 1995). As part of the Rock Island Mitigation Agreement between Chelan County Public Utility District and the fishery management parties (RISPA 1989), a supplementation (supportive breeding) program was initiated in 1989 on the Chiwawa River to mitigate smolt mortality resulting from the operation of Rock Island Hydroelectric Project. EFH uses broodstock collected at a weir on the Chiwawa River, although in recent years hatchery fish have been collected at Tumwater Dam. Similarly, the MFHC uses returning adults collected at weirs on the Methow River and its tributaries, the Twisp and Chewuch Rivers (Chapman et al. 1995; Bugert 1998). Although low run size and trap efficiency has resulted in most broodstock being collected from the hatchery outfall or in some years Wells Dam,
progeny produced from these programs are reared at and released from satellite sites on the tributaries where the adults were collected. Numerous other facilities have reared spring-run Chinook salmon on an intermittent basis.

## Previous Genetic Studies - Population differentiation

Waples et al. (1991a) examined 21 polymorphic allozyme loci in samples from 44 populations of Chinook salmon in the Columbia River Basin. These authors reported three major clusters of Columbia River Basin Chinook salmon: 1) Snake River springand summer-run Chinook salmon, and mid and upper Columbia River spring-run Chinook salmon, 2) Willamette River spring-run Chinook salmon, 3) mid and upper Columbia River fall- and summer-run Chinook salmon, Snake River fall-run Chinook salmon, and lower Columbia River fall- and spring-run Chinook salmon. Utter et al. (1995) examined allele frequency variability at 36 allozyme loci in samples of 16 upper Columbia River Chinook populations. Utter et al. (1995) indicated that spring-run populations were distinct from summer- and fall-run populations, where the average genetic distance between spring-run and late-run Chinook were about eight times the average of genetic distances between samples within each group. Additionally, allele frequency differences among spring-run populations were considerably greater than that among summer- and fall-run populations in the upper Columbia River. Utter et al. (1995) also reported hatchery populations of spring-run Chinook salmon were genetically distinct from natural spring-run populations, but hatchery populations of fall-run Chinook salmon were not genetically distinct from natural fall-run populations.

As part of an evaluation of the relative reproductive success for the Chiwawa River supplementation program, Murdoch et al. (2006), used eleven microsatellite loci to assess population differentiation among spring Chinook salmon population samples in the upper Wenatchee River. Murdoch et al. (2006) reported a $>99 \%$ accuracy of correctly identifying spring-run and fall-run Chinook from the Wenatchee River. They also reported slight, but significantly different genetic variation among wild spring populations and between wild and hatchery stocks. Yet, since the spring-run populations
are genetically similar, identifying individuals genetically from the upper tributaries of the Wenatchee River was difficult. This result is exemplified in their individual assignment results, where $<8 \%$ of spring-run individuals, hatchery or wild, were correctly assigned using their criterion of an LOD (log of odds) score greater than 2 . Murdoch et al. (2006) also reported contemporary natural spring Chinook show heterozygote deficit and low linkage disequilibrium (LD), while contemporary hatchery spring Chinook show heterozygote excess and high LD.

Williamson et al. (submitted) have continued the work of Murdoch et al. (2006) by analyzing Chiwawa River demographic data from 1989 - 2005 to estimate the proportions of recruits that were produced by Chinook with hatchery or wild origin. In an "ideal" population, the genetic size (i.e., effective size or $\mathrm{N}_{\mathrm{e}}$ ) and the census size are equal; however various demographic factors such as unequal sex ratios and variance in reproductive success among individuals reduces the genetic size below the census size. It is generally thought that the genetic size is approximately $10-33 \%$ the census size (Bartley et al. 1992; RS Waples pers. comm.), although values have been reported outside this range (Araki et al. 2007; Arden and Kapuscinski 2003; Heath et al. 2002). Despite being difficult to estimate, the effective population size in many respects is a more important parameter to know than census size, because $\mathrm{N}_{\mathrm{e}}$ determines how genetic diversity is distributed within populations and how the forces of evolution (i.e., forces that change genetic diversity over time) will affect the genetic variation present.

Williamson et al. (submitted) used demographic data to 1 ) investigate the effect of unequal sex ratio on genetic diversity, 2) investigate the effect of variation in reproductive success on genetic diversity, 3) investigate the effect of fluctuations in population size on genetic diversity, and 4) estimate the effective population size, using the inbreeding method (Ryman and Laikre 1991). Most importantly, they use demographic data from 1989 - 2000 to assess the impact of the Chiwawa Hatchery Supplementation Program on the effective population size of natural-origin Chiwawa River spring Chinook. They estimate that the $\mathrm{N}_{\mathrm{e}}$ of naturally spawning Chiwawa Chinook (i.e., both hatchery- and wild-origin fish on the spawning grounds) from 1989 -

1992 was $\mathrm{N}_{\mathrm{e}}=2683$ and in $1997-2000$ was $\mathrm{N}_{\mathrm{e}}=989$. They compare spawning ground $\mathrm{N}_{\mathrm{e}}$ to estimates calculated from combined broodstock and naturally spawning Chinook demographic data. The combined inbreeding $\mathrm{N}_{\mathrm{e}}$ estimate from $1989-1992$ was $\mathrm{N}_{\mathrm{e}}=$ 147 and in $1997-2000$ was $\mathrm{N}_{\mathrm{e}}=490$. Williamson et al. (submitted) argue that since the combined $\mathrm{N}_{\mathrm{e}}$ estimate is lower than the naturally spawning estimate, the supplementation program has had a negative impact on the Chiwawa River $\mathrm{N}_{\mathrm{e}}$.

Williamson et al. (submitted) also present genetic data for Chinook recovered on spawning grounds in upper Wenatchee River tributaries in 2004 and 2005. These genetic data are derived from the Murdoch et al. (2006) study. They compare samples collected from Chiwawa River (i.e., hatchery and wild), White River, Nason Creek, and Leavenworth Hatchery. Additionally, they include a 1994 Chiwawa River wild smolt sample for comparison with the 2004 brood year. Williamson et al. (submitted) report statistically significant genetic differentiation among Chiwawa River, White River and Nason Creek. Additionally, they report that the 1994 and 2004 Chiwawa River wild samples are not statistically different, but the 2004 Chiwawa wild and hatchery collections are statistically different.

## Study Objectives

This study investigated within and among population genetic diversity to assess the effect of the Chiwawa Hatchery's supplemental program on the natural Chiwawa River spring Chinook population. Differences among temporal population samples, the census size, heterozygosity, and allelic diversity were documented. We investigated population differentiation between the Chiwawa River natural and hatchery samples, and among all temporally replicated samples from the Wenatchee River watershed using microsatellite DNA allele frequencies and the statistical assignment of individual fish to specific populations. To assess the genetic effect of the hatchery program, correlation between census and effective population sizes were investigated using temporally replicated samples obtained before and after the supplementation program operation. To address the hypotheses associated with Objective 3 in Murdock and Peven (2005) we developed
eleven specific "Tasks" (Blankenship and Murdoch 2006), to which we analyzed specific genetic data. We present the results from these analyses specific to each individual Task.

## Methods and Materials

## Tissue collection and DNA extraction

We analyzed thirty-two population collections of adult spring Chinook salmon (Oncorhynchus tshawytscha) obtained from the Wenatchee River between 1989 and 2006 (Table 1). Nine collections of natural Chinook adults from the Chiwawa River ( $\mathrm{n}=501$ ), and nine collections of Chiwawa Hatchery Chinook ( $\mathrm{n}=595$ ) were collected at a weir located in the lower Chiwawa River. The 1993 and 1994 Chiwawa Hatchery samples are smolt samples from the 1991 and 1992 hatchery brood years, respectively. Additional samples were collected from upper Wenatchee River tributaries, White River, Little Wenatchee River, and Nason Creek. Six collections of natural White River Chinook ( $\mathrm{n}=179$ ), one collection from the Little Wenatchee ( $\mathrm{n}=19$ ), and six collections from Nason Creek ( $\mathrm{n}=268$ ) were obtained. Single collections were obtained for Chinook spawning in the mainstem Wenatchee River and Leavenworth National Fish Hatchery. An additional out-of-basin collection from Entiat River was also included in the analysis. Samples collected in 1992 or earlier are scale samples. All other samples were either fin clips or operculum punches, stored immediately in ethanol after collection. DNA was extracted from stored tissue using Nucleospin 96 Tissue following the manufacturer's standard protocol (Macherey-Nagel, Easton, PA, U.S.A.).

## Laboratory analysis

We performed polymerase chain reaction (PCR) amplification on each fish sample using the 13 fluorescently end-labeled microsatellite marker loci standardized as part of the GAPS project (Seeb et al. in review). GAPS genetic loci are: $\mathrm{Ogo2}$, $\mathrm{Ogo4}$ (Olsen et al. 1998); Oki100 (unpublished); Omm 1080 (Rexroad et al. 2001); Ots201b (unpublished); Ots208b, Ots211, Ots212, and Ots213 (Grieg et al. 2003); Ots3M, Ots 9 (Banks et al.
1999); OtsG474 (Williamson et al. 2002); Ssa408 (Cairney et al. 2000). PCR reaction volumes were $10 \mu \mathrm{~L}$, and contained $1 \mu \mathrm{~L} 10 \mathrm{x}$ PCR buffer (Promega), $1.0 \mu \mathrm{~L} \mathrm{MgCl2}$ (1.5 mM final) (Promega), $0.2 \mu \mathrm{~L} 10 \mathrm{mM}$ dNTP mix (Promega), and 0.1 units/mL Taq DNA polymerase (Promega). Loci were amplified as part of multiplexed sets, so primer molarities and annealing temperatures varied. Multiplex one had an annealing temperature of $50^{\circ} \mathrm{C}$, and used 0.37 Molar (M) Oki100, 0.35 M Ots 201 b , and 0.20 M Ots208b, and 0.20 M Ssa 408 . Multiplex two had an annealing temperature of $63^{\circ} \mathrm{C}$, and used $0.10 \mathrm{M} \mathrm{Ogo2}$, and 0.25 M of a non-GAPS locus (Ssa 197). Multiplex three had an annealing temperature of $56^{\circ} \mathrm{C}$, and used $0.18 \mathrm{M} \mathrm{Ogo4}, 0.18 \mathrm{M} \mathrm{Ots} 213$, and 0.16 M OtsG474. Multiplex four had an annealing temperature of $53^{\circ} \mathrm{C}$, and used 0.26 M Omm1080, and 0.12 M Ots 3 M . Multiplex five had an annealing temperature of $60^{\circ} \mathrm{C}$, and used 0.30 M Ots $212,0.20 \mathrm{M}$ Ots 211 , and 0.10 M Ots 9 . Thermal cycling was conducted on either a PTC200 thermal cycler (MJ Research) or GeneAmp 9700 (Applied Biosystems) as follows: $95^{\circ} \mathrm{C}(2 \mathrm{~min}) ; 30$ cycles of $95^{\circ} \mathrm{C}$ for $30 \mathrm{sec} ., 30 \mathrm{sec}$. annealing, and $72^{\circ} \mathrm{C}$ for 30 sec .; a final $72^{\circ} \mathrm{C}$ extension and then a $10^{\circ} \mathrm{C}$ hold. PCR products were visualized by electrophoresis on an ABI 3730 automated capillary analyzer (Applied Biosystems). Fragment analysis was completed using GeneMapper 3.7 (Applied Biosystems). Standardization of genetic data to GAPS allele standards was conducted following Seeb et al. (in review).

## Genetic data analysis

Assessing within population genetic diversity - Heterozygosity measurements are reported using Nei's (1987) unbiased gene diversity formula (i.e., expected heterozygosity) and Hedrick's (1983) formula for observed heterozygosity. Both tests are implemented using the microsatellite toolkit (Park 2001). We used GENEPOP version 3.4 (Raymond and Rousset 1995) to assess Hardy-Weinberg equilibrium (HWE), where deviations from the neutral expectation of random associations among alleles are calculated using a Markov chain method (5000 iterations in this study) to obtain unbiased estimates of Fisher's exact test. Global estimates of Fis according to Weir and Cockerham (1984) were calculated using GENEPOP version 3.4. Genotypic linkage disequilibrium was calculated following Weir (1979) using GENEPOP version 3.4.

Linkage results for population collections are reported as the proportion of pairwise (locus by locus) tests that are significant (alpha $=0.01$ ). Linkage disequilibrium is considered statistically significant if more than $5 \%$ of the pairwise tests based on permutation are significant for a collection.

Within- and among-population genetic differentiation - The temporal stability of allele frequencies within populations, and pairwise differences in allele frequencies among populations were assessed using several different procedures. First, we tested for differences in allele frequencies among populations defined in Table 1 using a randomization chi-square test implemented in GENEPOP version 3.4 (Raymond and Rousset 1995). This procedure tests for differences between pairs of populations where alleles are randomized between the populations (i.e., genic test). The null hypothesis for this test is that the allele frequency distributions between two populations are the same. A low p-value should be interpreted as the allele frequency distributions being compared are unlikely to be samples drawn from the same underlying distribution.

Second, to graphically describe allele frequency differences among populations we conducted a nonmetric multidimensional scaling analysis using allele-sharing distance matrices from two different data sets. Pairwise allele-sharing distances are calculated as 1 - (mean over all loci of the sums of the minima of the relative frequencies of each allele common to a pair of populations). To calculate the allele-sharing distances for each pair of populations we used PowerMarker v3.25 (Liu and Muse 2005). Nonmetric multidimensional scaling is a technique designed to construct an n-dimensional "map" of populations, given a set of pairwise distances between populations (Manly 1986). The output from this analysis is a set of coordinates along $n$-axes, with the coordinates specific to the number of n-dimensions selected. To simplify our analysis we selected a 2-dimensional analysis to represent the relative positions of each population in a typical bivariate plot. The goodness of fit between the original allele-sharing distances and the pairwise distances between all populations along the 2-dimensional plot is measured by a "stress" statistic. Kruskal (in Rohlf 2002) developed a five-tier guide for evaluating stress levels, ranging from a perfect fit (stress=0) to a poor fit (stress=0.40). We
conducted the nonmetric multidimensional scaling analysis for one data set containing Chiwawa natural- and hatchery-origin collections, and another data set containing Chiwawa broodstock and in-river spawner collections. We used the mdscale module in MATLAB R2006b (The Mathworks 2006) to generate the nonmetric multidimensional scaling coordinates.

We examined the geographic and temporal structure of populations in the upper Wenatchee (Chiwawa River, Nason Creek, and White River, only) using a series of analyses of molecular variance (AMOVAs). Here, we defined an AMOVA as an analysis of variance of allele frequencies, as originally designed by Cockerham (1969), but implemented in Arlequin v2.1 (Schneider et al. 2000). These analyses permit populations to be aggregated into groups, and molecular variance is then partitioned into within collections, among collections, but within groups, and among group components. With this approach, we were able to determine how best to group populations, with "best" being defined as that grouping that accounts for the greatest proportion of among group variance. Furthermore, by partitioning molecular variance into three different hierarchical components, we are able to determine what level accounts for the majority of the molecular variance.

Finally, we explored the partitioning of molecular variance between among-individuals and among-populations using a principal component analysis and multi-locus estimates of pairwise FST, estimated by a "weighted" analysis of variance (Weir and Cockerham, 1984). Principal component analysis is a data-reduction technique whereby the correlation structure among variables can be used to combine variables into a series of multivariate components, with each original variable receiving a weighted value for each component based on its correlation with that component. Here, we used a program written by Warheit in MATLAB R2006b (The Mathworks 2006) that treats each allele for each locus as a single variable ( 13 loci $=26$ alleles or variables), and these 26 "variables" were arranged into 26 components, with each component accounting for a decreasing amount of molecular variance. Estimates of $\mathrm{F}_{\text {ST }}$ were calculated using GENETIX version 4.05 (Belkhir et al.1996). To determine if the FST estimates were
statistically different from random (i.e., no structure), 1000 permutations were implemented in GENETIX version 4.05 (Belkhir et al.1996).

Effective population size ( $\mathbf{N}_{\mathbf{e}}$ ) - Estimates of the effective population size were obtained using two methods, a multi-collection temporal method (Waples 1990), and a singlecollection method (Waples 2006) using linkage disequilibrium data. The temporal method assumes that cohorts are used, but we did not decompose the collection year samples into their respective cohorts using age data. Therefore, $\mathrm{N}_{\mathrm{e}}$ estimates that pertain to individual year classes of breeders are not valid; however the harmonic mean over all samples will estimate the contemporary $\mathrm{N}_{\mathrm{e}}$. Comparing samples from years $i$ and $j$, Waples' (1990) temporal method estimates the effective number of breeders ( $\left.\hat{\mathrm{N}}_{\mathrm{b}(\mathrm{i}, \mathrm{j},}\right)$ according to:

$$
\hat{\mathrm{N}}_{\mathrm{b}(\mathrm{i}, \mathrm{j})}=\frac{\mathrm{b}}{2\left(\hat{\mathrm{~F}}-1 / \hat{\mathrm{S}}_{\mathrm{i}, \mathrm{j}}\right)}
$$

The standardized variance in allele frequency ( $\hat{F}$ ) is calculated according to Pollack (1983). The parameter $b$ is calculated analytically from age structure information and the number of years between samples (Tajima 1992). The age-at-maturity information required to calculate b was obtained from Murdoch et al. (2006) for this analysis. They observed for Chiwawa Hatchery Chinook that $8.6 \%$ matured at age 2, 4\% at age 3, 87\% at age 4 , and $0.4 \%$ at age 5. For Chiwawa natural Chinook, Murdoch et al. (2006) observed that $1.8 \%$ matured at age 3, $81.6 \%$ at age 4 , and $16.7 \%$ at age 5 . The harmonic mean of sample sizes from years $i$ and $j$ is $\tilde{\mathrm{S}}_{\mathrm{i}, \mathrm{j}}$. Over all pairwise comparisons the harmonic mean of all $\hat{\mathrm{N}}_{\mathrm{b}(\mathrm{i}, \mathrm{j})}$ is $\tilde{\mathrm{N}}_{\mathrm{b}}$, the contemporary estimate of the effective population size $\left(\mathrm{N}_{\mathrm{e}}\right)$. SALMONNb (Waples et al. 2007) was used to calculate $\widetilde{\mathrm{N}}_{\mathrm{b}}$. As suggested by authors, alleles with a frequency below 0.05 were excluded from the analysis to reduce potential bias.

The method of Waples (2006) uses linkage disequilibrium (i.e., mean squared correlation of allele frequencies at different gene loci) as a means of estimating effective population size $\left(N_{e}\right)$ from a single sample. While this method is biased in some cases where $N_{e} / N$
ratio is less the 0.1 and the sample size is less than the true $\mathrm{N}_{\mathrm{e}}$, it has been shown to produce comparable results to the temporal method. Burrows' delta method is used to estimate LD, and a bias corrected estimate of $\mathrm{N}_{\mathrm{e}}$ is calculated after eliminating alleles with frequency less than 0.05 . This test was implemented using $\operatorname{LDN}_{\mathrm{e}}$ (Do and Waples unpublished). In age-structured species, $\mathrm{N}_{\mathrm{e}}$ estimates based on LD are best interpreted as the effective number of breeders $\left(\mathrm{N}_{\mathrm{b}}\right)$ that produced the sample (Waples 2006). $\mathrm{N}_{\mathrm{b}}$ should be multiplied by the mean generation length (i.e., 4 in this case) to obtain an overall estimate of $\mathrm{N}_{\mathrm{e}}$ based on an $\mathrm{N}_{\mathrm{b}}$ estimate. We analyzed collections categorized by spawning location (i.e., hatchery broodstock or in-river) and did not analyze collections categorized by origin (i.e., hatchery or natural). Waples' (2006) method estimates $\mathrm{N}_{\mathrm{e}}$ from observed LD, therefore the corresponding $\mathrm{N}_{\mathrm{e}}$ estimates for the hatchery collections would be low and the estimates for the natural collections would be high. Yet, since the supplementation program is integrated, and hatchery fish can spawn naturally, we feel it inappropriate to analyze the hatchery and natural samples as if they were separate, which would essentially partition all the LD into the hatchery samples.

Each collection has an $\mathrm{N}_{\mathrm{b}}$ estimate and an associated confidence interval. If the confidence interval includes infinity, it means that sampling error accounts for all the LD observed (i.e., empirical LD is less than expected LD). The usual interpretation is that there is no evidence for any disequilibrium caused by genetic drift in a finite number of parents. Since the LD method estimates the number of breeders that contributed to the sample being analyzed, in order to calculate an $\mathrm{N}_{\mathrm{e}} / \mathrm{N}$ ratio, the appropriate census size must be used. The census size used to derive a ratio was the estimate four years prior to the collection analyzed using LD, which assumed a strict four-year-old lifecycle, although the observed proportion of four-year-olds was approximately $85 \%$ each year. The census numbers (Table 2) used to calculate the ratios for Chiwawa broodstock and in-river spawners were combined NOS (natural-origin spawners) and HOS (hatcheryorigin spawners) census estimates.

Individual assignment - A population baseline file was constructed containing all 1704 individual Chinook from 34 population collections (Table 1; Chiwawa origin data set
plus all samples from other populations). All individuals in the baseline had geneotypes that included nine or more loci. Individual Chinook were assigned to their most likely population of origin based on the partial Bayesian criteria of Rannala and Mountain (1997), using a "jack-knife" procedure, where each individual to be assigned was removed from the baseline prior to the calculation of population likelihoods. This procedure was implemented in a program written by Warheit in MATLAB R2006b (The Mathworks 2006). Two assignment criteria were used, 1) the population with the largest posterior probability for an individual was the "most-likely" population of origin (i.e., all individuals assigned to a collection), and 2) an assignment was consider valid only if the posterior probability was greater than or equal to 0.9 . Please note that while the analysis used 34 population collections to assign Rannala and Mountain likelihoods for each individual, these likelihoods were aggregated based on "population" (i.e., Chiwawa, Nason, White, and so on) and posterior probabilities were calculated for population location, rather than individual collections.

## Results and Discussion

In this section we combine our presentation and interpretations of the genetic analyses. Additionally, this section will be organized based on the task list presented in the study plan. Overall conclusions are provided following this section.

## Task 1: Determine trend in census size for Chiwawa River spring Chinook.

Census data from 1989 - 2005 are provided in Table 2 for the Chiwawa Hatchery broodstock and spring Chinook present in the Chiwawa River. The demographic data for naturally spawning Chinook are based on redd sampling and carcass surveys, while broodstock data are based on Chiwawa hatchery records. As the supplementation program is integrated by design, we also present the proportion of natural-origin broodstock ( pNOB ) incorporated into the hatchery, in addition to the number of naturalorigin (NOS) and hatchery-origin (HOS) spawners present in Chiwawa River. The
census size fluctuated yearly, and a general reduction in census size was observed in the mid to late 1990's. This trend was apparent in both the broodstock and in the river. The arithmetic mean census size from 1989 - 2005 for the Chiwawa Hatchery (i.e., broodstock) was $\mathrm{N}=87.5$ per year. The arithmetic mean census size from 1989 - 2005 for the Chiwawa River (i.e., NOS and HOS combined) was $\mathrm{N}=961.9$ per year. For collection years when adult Chiwawa hatchery-origin fish would have been absent in the Chiwawa River (1989-1992), the arithmetic mean of natural Chiwawa Chinook census size is $\mathrm{N}=962.7$. We will use this number as the baseline census size to assess if census size has changed. We used two different values for the contemporary census size in the Chiwawa River, NOS only and NOS + HOS. Additionally, we used collection years 2002-2005 for the contemporary NOS and HOS estimates, as these are the most recent data and the number of years included for estimation is the same as the pre-hatchery estimate above (i.e., four years). For NOS only, the arithmetic mean census size from 2002-2005 was $\mathrm{N}=536.0$. For total census size (i.e., NOS and HOS combined), the arithmetic mean census size from 2002 - 2005 was $\mathrm{N}=1324.0$. For the demographic data presented here, the contemporary census size is larger than the census estimate derived from the years prior to hatchery operation.

## Task 2: Document the observed genetic diversity.

## Genetic Diversity Categorized By Origin

For Chiwawa River collections categorized by origin (Table 1A), substantial genetic diversity was observed, with heterozygosity estimates over all loci, having a mean of 0.80. Genetic diversity was consistent with expected Hardy-Weinberg random mating genotypic proportions for ten of the eighteen collections. Eight of the nine Chiwawa natural collections were consistent with HWE, and two of nine Chiwawa Hatchery collections were consistent with HWE. FIS is observed to be slight for all Chiwawa population collections, suggesting individuals within collections do not show excessive homozygosity.

The deviations from HWE observed were generally associated with hatchery collections. The two smolt collections (i.e., 1993 and 1994) showed significant deviations from HWE, which may be a function of non-random hatchery practices involving the contributing natural-origin parental broodstocks (i.e., 1991 and 1992 cohort). Deviations from HWE in the remaining hatchery collections may be the result of few individuals being represented in the broodstock (see below).

Additionally, linkage disequilibrium (LD) was also common for Chiwawa hatcheryorigin collections and minimal for Chiwawa natural-origin collections. The random association of alleles between loci (i.e., linkage equilibrium) is expected under ideal conditions. LD is observed when particular genotypes are encountered more than expected by chance. Laboratory artifacts (e.g. null alleles) or physical linkage of loci on the same chromosome can cause LD, but the LD we observed was not associated with certain locus combinations, which you would expect if either artifacts or physical linkage were the cause of LD. LD was observed for seven of the nine hatchery-origin collections. As with the deviations from HWE, the high LD in the 1993 and 1994 hatchery-origin collections may be a result of non-random hatchery practices. The substantial LD observed in the hatchery-origin adult collections (collection years 2000, 2001, 2004, and 2006) might be the result of small parental broodstock sizes contributing to those returning adults. During the mid 1990's, the Chiwawa broodstock size was low, with zero individuals collected in 1995 and 1999; so fewer individuals would be contributing to the hatchery adult returns than the natural. This idea is corroborated by the lower LD observed for the 2005 hatchery-origin collection, which had a contributing parental broodstock size in 2001 (i.e., the major contributing parental generation) approximately eight times as large as the previous few collection years (Table 2). LD reappears in the 2006 Chiwawa hatchery-origin collection, which had a contributing parental broodstock size (i.e., for the most-part, the 2002 hatchery brood year) five times lower (Table 2) than that of the 2005 collection.

While seven of nine hatchery-origin collections showed significant LD, only one natural origin collection showed LD, and for this collection, only $10 \%$ of the loci-pairs were in
disequilibrium (Table 1). The fact that LD predominated in the hatchery samples, suggests that variance in reproductive success (i.e., overrepresentation of particular parents) is higher in the hatchery-origin than in natural-origin collections.

## Genetic Diversity Categorized By Spawning Location

For upper Wenatchee River collections categorized by spawning location (Table 1B), substantial genetic diversity was observed, with heterozygosity estimates over all loci, having a mean of 0.79 and ranging from a low of 0.69 (1993 White River) to 0.85 (1993 Little Wenatchee). Genetic diversity was consistent with HWE for nineteen of twentynine population collections. For the collections that departed from HWE, seven were from the Chiwawa River, one was from Leavenworth Hatchery, one was the Wenatchee mainstem collection of hatchery-origin - naturally spawning fish, and one was from the White River. FIS is observed to be slight for all population collections except the 1993 White River collection ( $10 \%$ heterozygote deficit) (Table 1B). Collections deviating with HWE generally correlated with collections having high LD. Twelve population collections showed a proportion of pairwise linkage disequilibrium tests (across all loci) greater than 5\% (Table 1B), eight of which were Chiwawa collections.

Starting in 1996, spawning location collections are composed of both natural- and hatchery-origin samples. The LD seen in the later spawning location collections may be caused by an admixing effect (i.e., mixing two populations), where random mating has not had the chance to freely associate alleles into genotypes. Interestingly, there appears to be a trend of reducing LD through time within the broodstock collections (Table 1B), which suggests that a "homogenizing" effect is taking place within the Chiwawa River. This observation is discussed more fully in Task 3 below.

## Task 3: Test for population differentiation among collections within the Chiwawa River and associated supplementation program.

## Introduction

Task 3 was designed to address two hypotheses listed as part of Objective 3 in Murdoch and Peven (2005):

- Ho: Allele frequency Hatchery $=$ Allele frequency Naturally produced $=$ Allele frequency Donor pop.
- Ho: Genetic distance between subpopulations Year $\mathrm{x}=$ Genetic distance between subpopulations Year y

Murdoch and Peven (2005) proposed these two hypotheses to help evaluate the Chiwawa supplementation program through the "Conceptual Process" (Figure 5 in Murdoch and Peven 2005; repeated here as Figure 1). There are two components to the first hypothesis, which must be considered separately. The first component involves comparisons between natural-origin populations in the Chiwawa to determine if there have been changes in allele frequencies or genetic distances, through time starting with the donor population. Documenting a change does not necessarily indicate that the supplementation program has directly affected the natural origin fish, as additional tests would be necessary to support that hypothesis. The intent of the second component is to determine if the hatchery produced populations have the same genetic composition as the naturally produced populations.

Although on the surface these two components and their associated comparisons may appear simple, from a hypothesis-testing perspective the analyses are complicated by the fact that natural-origin fish may have had hatchery-origin parents, and hatchery-origin fish may have had natural-origin parents. As such, we organized the Chiwawa genetic data into three data sets: (1) fish origin (hatchery versus natural), (2) spawning location (hatchery broodstock versus in-river (natural) spawners), and (3) four "treatment" groups (1. hatchery-origin hatchery broodstock, 2. hatchery-origin natural spawner, 3. naturalorigin natural spawner, and 4. natural-origin hatchery broodstock). We conducted separate analyses using each of the three data sets, with each analysis touching on some aspect of the components necessary to move through the Conceptual Process (Figure 1).

## Hatchery- Versus Natural-Origin

We address the following questions with the origin data set:

1. Are there changes in allele frequencies and allele sharing distances in the naturalorigin collections from pre-supplementation to today?
2. Are there changes in allele frequencies and allele sharing distances in the hatchery-origin collections from early supplementation to today?
3. Are there significant differences in allele frequencies and large allele sharing distances between hatchery- and natural-origin adults from a collection year, and has this pattern changed through time?

Genic Differentiation Tests - We explicitly tested the hypothesis of no significant differentiation within natural- or hatchery-origin collections from the Chiwawa River using a randomization chi-square test. We show the results for the pairwise comparisons among natural-origin collections from the Chiwawa River populations in the first block of the second page of Table 3. Ten of the 36 ( $28 \%$ ) pairwise comparisons have highly significant allele frequency differences, while only 12 of the 36 comparisons ( $33 \%$ ) showed no significant differences. Eight of these 12 comparisons involved the 1996 collection, which included only eight samples and therefore provided little power to differentiate allele frequencies. If we exclude the 1996 collection, only $14 \%$ of the pairwise comparisons showed no significant differences, and here all but one of these comparisons involved the 1989 collection. The 1989 collection appeared to be the least differentiated collection in the natural-origin data set in that all pairwise comparisons were either not significant, or only mildly significant at the nominal critical value. No comparisons involving the 1989 collection were significant using a Bonferroni-corrected critical value, and 1989 is the only natural-origin collection in our data set that can be classified as "pre-supplementation."

We can interpret these results to indicate that although there appears to be significant year-to-year differences in allele frequencies among post-supplementation collections, the allele frequencies between each post-supplementation collection and the 1989 presupplementation collection are not greatly different. However, the level of differentiation
does increase from the early post-supplementation years to the more recent years (2001, 2004-2006), although the statistical level of this significance never exceeds the Bonferroni-corrected critical value. Finally, sample sizes were also small for the 1989 collection ( $\mathrm{n}=36$ ) and we cannot eliminate a reduction in power as a contributing factor for the lack of significance for these tests.

As with the hatchery-origin collections, most pairwise comparisons of allele frequencies between hatchery-origin samples were significant (Table 3, first page, upper block). Out of the 36 pairwise comparisons, all but three are significant at some level, and most comparisons are highly significant. Similar to the natural-origin analysis, the nonsignificant results were limited to comparisons involving the 1996, which included only eight samples.

As a result of this analysis we reject the hypothesis that there was no significant differentiation among natural- or hatchery-origin collections from the Chiwawa River. Furthermore, the allele frequencies of the hatchery-origin collections are significantly different from those of natural-origin collections (Table 3, first page, second block). For those fish collected in the same year, allele frequencies are significantly different between hatchery- and natural-origin collections, although in 2005 the level of significance was below the Bonferroni critical value (Table 3). The next step is to examine the pattern of allelic differentiation to discover first if there is a trend among the data, and second, if this trend suggests that the allele frequency differences among Chiwawa River natural-origin fish collections has been affected by the hatchery-origin fish.

Allele-sharing and Nonmetric Multidimensional Scaling - We constructed a pairwise allele-sharing distance matrix for all hatchery- and natural-origin collections from the Chiwawa River and subjected this matrix to a nonmetric multidimensional scaling analysis, restricting the analysis to two dimensions (Figure 2). The stress statistic for this analysis is 0.09 , a value Kruskal (in Rohlf 2002) listed as a good to excellent fit between the actual allele-sharing distances and the Euclidean (straight-line) distances in the plot.

In other words, Figure 2 is a good visual representation of the allele sharing distance matrix; collections with a high percentage of alleles shared will be closer to each other than collections with a lower percentage of alleles shared.

With the exception of the two outlier years (1996 and 1998) the Chiwawa natural-origin collections form a tight cluster indicating an overall common set of shared alleles among these collections. Even if we ignore the 1996 and 1998 hatchery-origin collections, there appears to be a greater variance in shared alleles among the Chiwawa hatchery-origin collections than the natural-origin collections (Figure 2). In fact, the median percentage of alleles shared among the Chiwawa natural-origin collections is $76 \%$ compared with $69 \%$ alleles shared among the Chiwawa hatchery-origin collections.

Also, there appears to be a convergence in allele sharing distances (i.e., a decrease in allele frequency differences) between the hatchery- and natural-origin fish from the late 1980s/early 1990s to 2006. The series of red arrows in Figure 2 represent the progression of change in hatchery-origin allele sharing distances from 1996 (first adult hatchery origin fish in our analysis) to 2006 and this progression is decidedly in the direction of the natural-origin cluster. However, the most recent natural-origin collections (2001, 2004-2006) appear to have pulled closer to the hatchery-origin collections, compared with the 1989 natural-origin collection (note the close proximity of the 2000 and 1989 natural-origin collections). Nevertheless, the cluster of natural-origin collections adjacent to the hatchery-origin collections in Figure 2 also includes the 1993 natural-origin collection. Qualitatively, it appears that the initial hatchery-origin and natural-origin collections were more different from each other in terms of the percentage of shared alleles than are the most recent hatchery- and natural-origin collections. This may have been a result of a non-random sample of natural-origin fish that was used as broodstock in the initial years of the supplementation program (see discussion in Task 2 concerning deviations from HWE and linkage disequilibrium).

That being said, we do need to emphasize that Figure 2 is dominated by five outlier collections (two each from the 1996 and 1998 collections, and the 1994 smolt collection).

The 1996 and 1998 collections are characterized by small samples sizes, and the 1994 smolt collection has nearly all pairs of loci in linkage disequilibrium (Table 1). If we eliminate these five outlier groups, both the hatchery- and natural-origin collections form a relatively tight cluster. Excluding the five outliers, the median percentage of shared alleles among all pairwise combinations of Chiwawa hatchery versus Chiwawa natural collections is $76 \%$. This compares with a median pairwise percentage of $79 \%$ among only Chiwawa natural-origin collections. That is, there are nearly as many alleles shared between the hatchery-origin and natural-origin collections as there are among the naturalorigin collections themselves. There is also a narrowing of differences between naturaland hatchery-origin fish from the same collection years from 1993 ( $76 \%$ shared alleles) through 2006 (83\% shared alleles).

If allelic differentiation among collections is a function of genetic drift, we would expect a positive correlation between the number of years between two collections and the allele sharing distance. That is, if genetic drift is the primary cause of allele frequency differences between two collections, the greater the number of years between the two collections the larger the allele-sharing distance. For both the natural- and hatcheryorigin collections we examined the relationship between the number of years between a pair of collections and the collections' allele-sharing distance (Figure 3). Although the relationship between time interval and allele distance appears to be a positive function in the natural collections, the slope of the regression line is 0.0017 , and is not significantly different from zero. Furthermore, the correlation coefficient $\left(r^{2}\right)$ equals 0.1068 , which means that the time interval between collections accounts for only $10 \%$ of the pairwise differences in allelic distance. The hatchery-origin collections do show a significantly positive slope ( $0.0037 ; \mathrm{p}=0.0254$ ) and a regression coefficient nearly three times greater than that for the natural-origin collections. However, the correlation coefficient is still relatively small ( $\mathrm{r}^{2}=0.3290$ ), indicating that the time interval between collections accounts for one-third of the pairwise differences in allelic distance. The results suggest that if genetic drift is a factor in allelic differentiation between collections, it is only a minor factor, and appears to have affected the hatchery-origin collections more than the natural-origin collections.

If four-year-old fish dominate each collection year, we would expect a closer relationship among collections that are spaced at intervals of four years. The average percentage of alleles shared between two natural-origin collections that are separated by four years or a multiple of four years is $81 \%$, compared with $78 \%$ for natural-origin collections separated by years that are not divisible by four. Likewise, for hatchery-origin collections the average percentage of alleles shared is $80 \%$ and $75 \%$ for collections separated by years divisible and not divisible by four, respectively. Although the percent differences described above are relatively small, they are consistent with the idea that allelic differences between collections are a function of year-to-year variability among different cohorts of four year-old fish.

Summary - The allele frequencies within and between natural- and hatchery-origin collections are significantly different, but there does not appear to be a robust signal indicating that the recent natural-origin collections have diverged greatly from the pre- or early post-supplementation collections. Genetic drift will occur in all populations, but does not appear to be a major factor with the Chiwawa collections. We propose that the differences among collections are a function of differences in allele frequencies among cohorts of the four year-old fish that dominate each collection.

## Hatchery Broodstock Versus Natural (In-River) Spawners

We address the following questions with the spawner data set:

1. Are there changes in allele frequencies and allele sharing distances in the natural spawning collections from pre-supplementation to today?
2. Are there changes in allele frequencies and allele sharing distances in the hatchery broodstock collections from early supplementation to today?
3. Are there significant differences in allele frequencies and large allele sharing distances between hatchery and natural spawning adults from a collection year, and has this pattern changed through time?

Genic Differentiation Tests - For the most part there are significant differences in allele frequencies among collections for both the hatchery broodstock and natural spawners (Table 4), and these differences are consistent with the origin data set (Table 3). There are four collection years with paired samples (2001, 2004-2006) where we can compare allele frequency differences between the hatchery broodstock and natural spawners, within the same year. The 2001 hatchery broodstock and natural spawner collections have significantly different allele frequencies, but the level of significance decreased from 2001 to 2004, and become non-significant in 2005 and 2006 (Table 4). This indicates that by 2005, the hatchery broodstock and natural spawners collections were effectively sampling from the same population of fish. Additionally, the percentage of alleles shared between the hatchery broodstock and the natural spawners increased from $76 \%$ in 2001 to $86 \%$ in 2006 (allele sharing distance matrix, not shown). From this analysis, we conclude that although there are year-to-year differences in allele frequencies within the natural and hatchery spawner collections, there appears to be a convergence of allele frequencies within collection-year, between the natural and hatchery spawner populations.

Linkage Disequilibrium - Linkage disequilibrium is the correlation of alleles between two loci, and can occur for several reasons. If two loci are physically linked on the same chromosome, than alleles from each of these loci should be correlated. However, linkage between two loci can occur as a result of population bottlenecks, small population sizes, and natural selection. If any of these conditions had occurred or were occurring within the Chiwawa River system, we would expect to find substantial linkage disequilibrium in many or perhaps all Chiwawa collections. However, many Chiwawa collections, especially the natural-origin collections, do not show linkage disequilibrium (Table 1), and it would appear that the linkage disequilibrium within certain Chiwawa collections is not a function of the processes listed above. Linkage disequilibrium can also result if the collection is composed of an admixture. That is, if two or more reproductively isolated populations are combined into a single collection, the collection will show linkage disequilibrium. Each broodstock and natural spawning collection is composed of naturaland hatchery-origin fish. If these hatchery- and natural-origin fish are drawn from the
same population, the spawning collections should not show substantial linkage disequilibrium. However, if the hatchery- and natural-origin fish are from different populations (i.e., full hatchery - natural integration has not been achieved), the spawning collections should show substantial linkage disequilibrium.

There are only three Chiwawa spawning collections that are not composed of both hatchery- and natural-origin samples: 1989 (natural-origin, natural spawner), 1993 (natural-origin, hatchery broodstock), and 2001 (natural-origin, natural spawner). Of the 10 spawning collections with both hatchery- and natural-origin fish, seven show significant linkage disequilibrium. Two of the three collections that did not show linkage disequilibrium are the 1996 and 1998 hatchery broodstock collections, which are composed of only seven natural- and six hatchery-origin fish, and two natural- and 19 hatchery-origin fish, respectively. Within the hatchery broodstock collections with linkage disequilibrium, the percent of loci pairs showing linkage decreased from $32 \%$ in 2000 to $13 \%$ in 2001 and 2004, to only $1 \%$ and $5 \%$ in 2005 and 2006, respectively (Table 1). If the homogenization of allele frequencies of natural- and hatchery-origin fish was increasing from 2000 to 2006, we would expect a decrease in linkage disequilibrium among the broodstock collections. This is what occurred within the hatchery broodstock collections, but did not occur within the natural spawner collections, where the percent of loci pairs showing linkage was $18 \%$ in 2004, $6 \%$ in 2005, and $10 \%$ in 2006 (Table 1). Furthermore, the 2001 natural spawner collection, with no hatchery-origin component showed linkage disequilibrium with $9 \%$ of loci pairs.

There is no correlation between percent of loci pairs showing linkage disequilibrium and percent of broodstock composed of hatchery-origin fish $\left(r^{2}=0.0045\right)$. Furthermore, the natural spawner and hatchery broodstock collections were each composed of roughly the same average percentage of hatchery-origin fish ( $57 \%$ and $53 \%$, respectively). If the decrease in linkage disequilibrium among the hatchery broodstock collections from 2000 to 2006 was a result of a homogenization of allele frequencies of natural- and hatcheryorigin fish in the broodstock, the same degree of homogenization did not occur within the
natural spawner collections. This would occur if natural- and hatchery-origin fish spawning within the river remain segregated, either by habitat or by fish behavior.

Summary - As with the origin data set, there are significant allele frequency differences within and between hatchery broodstock and natural spawner collections. However, in recent years the allele frequency differences between the hatchery broodstock and natural spawner collections has declined. Furthermore, based on linkage disequilibrium, there is a genetic signal that is consistent with increasing homogenization of allele frequencies within hatchery broodstock collections, but a similar homogenization within the natural spawner collection is not apparent. These data suggest that there exists consistent year-to-year variation in allele frequencies among hatchery and natural spawning collections, but there is a trend toward homogenization of the allele frequencies of the natural- and hatchery-origin fish that compose the hatchery broodstock.

## Four Treatment Groups

Analyses of genetic differences between hatchery (broodstock) and natural spawner collections is confounded by the fact that each these two groups are composed of fish of natural- and hatchery-origin. To understand the effects of hatchery supplementation on natural-origin fish that spawn naturally, we needed to divide the Chiwawa data set into four mutually exclusive groups: (1) hatchery-origin hatchery broodstock, (2) hatcheryorigin natural spawner, (3) natural-origin hatchery broodstock, and (4) natural-origin natural spawner, with each group consisting of multiple collection years, for a total of 25 different groups.

Allele-sharing and Nonmetric Multidimensional Scaling -As with previous analyses discussed above, we constructed a pairwise allele-sharing distance matrix for all collections from each of these treatment groups and subjected this matrix to a nonmetric multidimensional scaling analysis, restricting the analysis to two dimensions. Figure 4 shows that five outlier groups dominate the allele-sharing distances within this data set. These outlier groups are also present in Figure 2, as discussed above, and Figure 2 and 4 resemble each other because the same fish are included in each analysis. The difference
between Figures 2 and 4 is that in Figure 4 the fish are grouped into collection year and the four treatment groups, rather than collection year and two treatment groups (hatcheryversus natural-origin).

Figure 4 does not provide useful resolution of the groups within the polygon, because the outlier groups dominate the allele sharing distances. We removed the five outlier groups from Figure 4, recalculated the allele sharing distances and subjected this new matrix to a multidimensional scaling analysis (Figure 5). Figure 5 shows separation among the 2001, 2004-2006 collections, but this separation does not necessarily indicate that within-year collections are more similar to each other than any collection is to a collection from another year. For example, the 2006 natural-origin natural spawner and the 2005 naturalorigin hatchery broodstock collections share $81 \%$ alleles, while the 2006 natural-origin natural spawner and 2006 hatchery-origin hatchery broodstock collections share $75 \%$ alleles. There does not appear to be any discernable pattern of change in allele-sharing distance among the collections relevant to pre- or post-supplementation. Although the 1989 pre-supplementation natural-origin collection appears distinct (Figure 5), the 1993 natural-origin hatchery broodstock collection appears quite similar to the 2005 and 2006 natural-origin collections (Figure 5). The 1993 natural-origin hatchery broodstock collection, although not technically pre-supplementation, is composed of fish whose ancestry cannot be traced to any Chiwawa hatchery fish. Therefore, there is no clear pattern of allele sharing change from pre-supplementation to recent collections.

There does appear to be some change in the average percentage of alleles shared within the 2001 to 2006 collections, with an increase from $74 \%$ in 2001 and 2004 to $78 \%$ and $79 \%$ in 2005 and 2006, respectively. The results provided by this analysis are consistent with the results presented in the origin and spawner data sets. That is, there are allele frequency and allele sharing differences among the collections, but analyses do not strongly suggest that these differences are a function of the supplementation program. Furthermore, there is also a weak signal that the hatchery and natural collections within the most recent years are more similar to each other than in the previous years.

Overall Genetic Variance - Although there are signals of allelic differentiation among Chiwawa River collections, there are no robust signs that these collections are substantially different from each other. We used two different analyses to measure the degree of genetic variation that exists among individuals and collections within the Chiwawa River. First, we conducted a principal component analysis using all Chiwawa samples with complete genotypes (i.e., no missing alleles from any locus). Although the first two principal component axes account for only $10.5 \%$ of the total molecular variance, a substantially greater portion of that variance is among individual fish, regardless of their identity, rather than among hatchery and natural collections (Figure 6). The variances in principal component scores among individuals are 11 and 13 times greater than the variance in scores among collections, along the first and second axes, respectively.

Second, we conducted a series of analyses of molecular variance (AMOVA) to ascertain the percentage of molecular variance that could be attributed to differences among collections. We organized these analyses to test also for differences in the hierarchical structure of the data. That is, we tested for differences among collections using the following framework:

- No organizational structure - all 25 origin-spawner collections considered separately
- Origin-spawner collections organized into 10 collection year groups
- Origin-spawner collections organized into 2 breeding location groups (hatchery versus natural)
- Origin-spawner collections organized into 2 origin groups (hatchery versus natural)
- Origin-spawner collections organized into the 4 origin-spawner groups

It is clear from this analysis that nearly all molecular variation, no matter how the data are organized, resides within a collection (Table 5). The percentage of total molecular variance occurring within collections ranged from $99.68 \%$ to $99.74 \%$. The among group variance component was limited to less than $0.26 \%$ and in all organizational structures,
except "no structure," the among group percentage was not significantly greater than zero. Furthermore, none of the organizational structures provided better resolution than "no structure" in terms of accounting for molecular variance within the data set. These results indicate that if there are significant differences among collections of Chiwawa fish, these differences account for less than one percent of the total molecular variance, and these differences cannot be attributed to fish origin or spawning location.

## Summary and Conclusions

We reject the null hypothesis that the allele frequencies of the hatchery collections equal the allele frequencies of the natural collections, which equals the allele frequency of the donor population. Furthermore, because the allele-sharing distances are not consistent within and among collections years, we also reject the second stated hypothesis discussed above. However, there is an extremely small amount of genetic variance that can be attributed to among collection differences. The allelic differentiation that does exist among collections does not appear to be a function of fish origin, spawning location, genetic drift, or collection year. Figure 5 and related statistics does suggest that hatchery and natural collections in 2005 and 2006 are more similar to each other than previous years' collections, and this would be expected in a successful integrated hatchery supplementation program.

Since each of these collection years are generally composed of four-year-old fish, the differentiation among these collections for the most part is differentiation among specific cohorts. The slightly greater percentage of alleles shared among collections that are separated in time by multiples of four years, compared with collections that are not separated in time as such, suggests that cohort differences may be the most important factor accounting for differences in allele frequencies among collections.

## Task 4: Develop a model of genetic drift.

See Task 3

# Task 5: Analyze spring Chinook population samples from the Chiwawa River and Chiwawa Hatchery from multiple generations. 

See Task 3

## Task 6: Analyze among population differences for upper Wenatchee spring Chinook.

Supplementation of the Chiwawa River spring Chinook population may affect populations within the Wenatchee River watershed other than the Chiwawa River stock. If the stray rate for Chiwawa hatchery-origin fish is greater than that for natural-origin fish, an increase in gene flow from the Chiwawa population into other populations may result. If this gene flow is high enough, Chiwawa River fish may alter the genetic structure of these other populations. Records from field observations indicate that hatchery-origin fish are present in all major spawning aggregates (A.R Murdoch, unpublished data), and these fish are successfully reproducing (Blankenship et al 2006). The intent of this task is to investigate if there have been changes to the genetic structure of the spring Chinook stocks within upper Wenatchee tributaries during the past 15-20 years, and if changes have occurred, are they a function of the Chiwawa River Supplementation Program? Therefore, we ask the following two questions:

1. Are allele frequencies within populations in the upper Wenatchee stable through time? That is, is there significant allelic differentiation among collections within upper Wenatchee populations?
2. Are the recent collections from the upper Wenatchee populations more similar to the Chiwawa population than earlier collections from the same populations?

For this task we analyzed natural spawning collections from the White River (naturalorigin), Little Wenatchee River (natural-origin), Nason Creek (natural-origin), and

Wenatchee mainstem (hatchery-origin), and hatchery collections from Leavenworth NFH and Entiat River NFH (Table 1). We also included in the analysis the natural- and hatchery-origin collections from the Chiwawa River. There are no repeated collections from Leavenworth, Entiat, Little Wenatchee, and Wenatchee mainstem (Table 1), so for many of the analyses we have limited our discussion to the Chiwawa River, White River, and Nason Creek collections. Furthermore, genetic structure of the Little Wenatchee collection, which consisted of only 19 samples, was unexpectedly quite different from the other collections. For example, the $\mathrm{F}_{\text {ST }}$ statistic measures the percent of total molecular variation that can be attributed to differences between populations. The median FST for all pairwise combinations of collections from all populations, except Little Wenatchee (33 populations, 528 individual $\mathrm{F}_{\text {ST }}$ statistics) equals $0.010(1 \%)$, with a range of 0.000 to 0.037 (Table 6). The median Fst $_{\text {St }}$ for the Little Wenatchee paired with all other collections ( 33 individual $\mathrm{F}_{\text {ST }}$ statistics) equals 0.106 ( $10.6 \%$ ), with a range of 0.074 to 0.121 . The ten-fold increase in the $\mathrm{F}_{\text {ST }}$ statistic indicates that either the Little Wenatchee spring Chinook is unique among the upper Wenatchee River stocks, or this 1993 collection is somehow aberrant. Therefore, we exclude the Little Wenatchee collection from many other analyses.

Population Differentiation - Table 3 provides the levels of significance for all pairwise genic differentiation tests. Most between-collection comparisons are highly significant, with no pattern of increasing or decreasing differentiation with time, and no differences when comparisons are made with Chiwawa hatchery- versus Chiwawa natural-origin fish. For example, excluding the outlier 1996 and 1998 Chiwawa hatchery- and naturalorigin collections, Nason Creek showed highly significant allele frequency differences between the Chiwawa hatchery- and natural-origin collections at $100 \%$ and $86 \%$ of the comparisons, respectively. The same comparisons with the White River produced 100\% and $93 \%$ highly significant allele frequency comparisons, respectively. Allele frequencies between Nason Creek and White River were likewise differentiated from each other.

The collection allele frequencies within the upper Wenatchee system are significantly different, and these differences do not appear to change as a function of time (Table 3). Nason Creek shows greater within-population year-to-year variation in allele frequencies than does the White River, with $47 \%$ of the pairwise comparisons showing highly significant differences, compared with only $13 \%$ for the White River. However, the 2005 and 2006 collections from the White River appear to be somewhat more differentiated from not only each other, but from the earlier collections from the White River.

Despite the high degree of temporal and spatial structure suggested by the genic differentiation tests, as described above for within-Chiwawa analysis (Task 3), most of the genetic variation within this data set occurs within populations, rather than between populations (Table 6). The FST values for most population comparisons are between 0.01 and 0.02 , indicating $1 \%$ to $2 \%$ among-population variance, with the remaining $98 \%$ to 99\% variance occurring within populations. The White River shows the highest median $\mathrm{F}_{\text {ST }}$ among the natural-origin collections, equal to 0.014 , compared with 0.009 for both the Nason Creek and Chiwawa natural-origin collections. The median $\mathrm{F}_{\text {ST }}$ for the Chiwawa hatchery-origin collections (0.012) was higher than that for the Chiwawa natural-origin collections.

Table 7 summarizes the information from the FST analyses, under five different temporal and spatial scenarios. Under all scenarios, over $99 \%$ of the molecular variance is within populations. There is significantly greater spatial structure among populations ("Origin") in 2005 and 2006 than from 1989 to 1996. That is, there appears to be more spatial structure among the Chiwawa hatchery-origin, Chiwawa natural-origin, White River, and Nason Creek now, than in 1989 to 1996, despite the potential homogenizing and cumulative effect of hatchery strays. However, we stress that the amount of molecular variance associated with the among population differences, despite being significantly greater than $0.00 \%$, is limited to only $0.43 \%$.

Allele-sharing and Nonmetric Multidimensional Scaling - As in the Chiwawa River data discussed above, we constructed an allele-sharing distance matrix and then subjected
that matrix to a multidimensional scaling analysis (Figure 7). Consistent with all previously discussed multidimensional scaling analyses, the 1996 and 1998 adult, and the 1994 smolt collections are outliers. There is clear separation between the White River collections and all other natural-origin and Chiwawa hatchery-origin collections, indicating that there are more alleles shared among the Nason Creek and Chiwawa collections, than with the White River collections. Furthermore, there is a slight separation between the Chiwawa natural-origin natural spawner collections and Nason Creek collections, suggesting different groups of shared alleles between these populations. There is more variation in the allele-sharing distances among collections involved with the Chiwawa hatchery (origin or broodstock) than any of the natural-origin collections, even if we exclude the 1994, 1996, and 1998 collections. This suggests that there is more year-to-year variation in the composition of hatchery-origin and hatchery broodstock than within natural-origin populations throughout the upper Wenatchee. All Wenatchee mainstem fish are hatchery-origin, and if these fish are from the Chiwawa Supplementation Program (rather than from Leavenworth), it is not unexpected that this collection would be plotted within the Chiwawa polygon (Figure 7).

Assignment of Individual to Populations - Finally, we conducted individual assignment tests whereby we assigned each individual fish to a population, based on a procedure developed by Rannala and Mountain (1997) (Table 8 and 9). Individual fish may be correctly assigned to the population from which they were collected, or incorrectly assigned to a different population. Incorrect assignments may occur if the fish is an actual migrant (i.e., source population different from population where collected), or because the genotype for that fish matches more closely with a population different from its source. If there are many individuals from a population incorrectly assigned to populations other than its source population, that original population is either unreal (i.e., an admixture), or there is considerable gene flow between that population and other populations. Furthermore, in assigning individuals to populations, we can either accept the assignment with the highest probability, regardless of how low that probability may be, or we can establish a more stringent criterion, such as to not accept an assignment unless the posterior probability is equal to or greater than 0.90 . This value is roughly
equal to having the likelihood of the most-likely population equal to 10 times that of the second most-likely population.

We provide a summary of the assignments in Tables 8 and 9. On average, nearly $50 \%$ of the fish are assigned incorrectly if we accept all assignments (Table 8), but the incorrect assignment rate drops to roughly $10 \%$ when we accept only those assignments with probabilities greater than 0.90 . However, with this more stringent criterion, nearly $64 \%$ of the fish go unassigned. These results indicate that the allele frequency distributions for these populations are very similar, and it would be very difficult to assign an individual fish of unknown origin to the correct population. If all fish are assigned, there is a $50 \%$ chance, overall, of a correct assignment. If you accept only those assignment with the 0.90 criterion, nearly two-thirds of the fish would be unassigned, but there is a $90 \%$ chance of correctly assigning those fish that are indeed assigned.

Of all the populations in the data set, there are fewer errors associated with assigning fish to the White River. If all fish are assigned (Table 8), $72 \%$ of those fish assigned to the White River, are actually from the White River (115 fish out of a total of 159 fish assigned to the White River). This compares to a rate of only $52 \%$ and $53 \%$ for Nason Creek and Chiwawa natural-origin, respectively, and $60 \%$ for the Chiwawa hatcheryorigin collections. With the 0.90 criterion (Table 9), $89 \%$ of the fish assigned to the White River, are actually from the White River, compared with $70 \%$ and $65 \%$ for Nason Creek and Chiwawa natural origin, respectively, and $81 \%$ for the Chiwawa hatchery origin.

When all fish are assigned, most of the incorrectly assigned fish from Nason Creek and White River are assigned to Chiwawa River, at roughly equal frequencies to the hatcheryand natural-origin populations. Incorrectly assigned fish to other populations occur at a slightly higher rate in Nason Creek than in the White River. However, when only those fish meeting the 0.90 criterion are assigned (Table 9), incorrectly assigned fish from Nason Creek are distributed among White and Chiwawa Rivers, as well as Leavenworth NFH, and the Entiat NFH. Mis-assignment to the Chiwawa hatchery-origin was the
highest among the Nason Creek collections, equal to nearly $14 \%$. This contrasts with the White River where mis-assignments do not exceed $7 \%$ anywhere, and there is a roughly even distribution of mis-assignments among Nason Creek and Chiwawa River collections.

Summary and Conclusions - There is little geographic or temporal structure among populations within the upper Wenatchee systems. Among population molecular variance is limited to $1 \%$ or less. The little variance that can be attributed to among populations indicates that the White River is more differentiated from the Chiwawa and Nason populations than these populations are from each other. Furthermore, although we cannot rule out a hatchery effect on the Nason Creek and White River populations, there is no indication there has been any temporal changes in allele frequencies within these populations that can be attributed directly to the Chiwawa River Supplementation Program. In fact, Table 7 weakly suggests that there is more differentiation among these populations now, than there was before or at the early stages of Chiwawa supplementation.

Therefore, returning to our two original questions, there are significant differences in allele frequencies among collections within populations, and among populations within the upper Wenatchee spring Chinook stocks. However, these differences account for a very small portion of the overall molecular variance, and these populations overall are very similar to each other. There is no evidence that the Chiwawa River Supplementation Program has changed the allele frequencies in the Nason Creek and White River populations, despite the presence of hatchery-origin fish in both these systems. Finally, of all the populations within the Wenatchee River, the White River appears to be the most distinct. Yet, this distinction is more a matter of detail than of large significance, as the median $\mathrm{F}_{\text {ST }}$ between White River collections and all other collections (except the Little Wenatchee) is less than $1.5 \%$ among population variance.

## Task 7: Calculate the inbreeding effective population size using demographic data for each sample year, and document the ratio of census to effective size.

This analysis was completed by Williamson et al. (submitted).

## Task 8: Calculate LD $\mathbf{N}_{\mathrm{b}}$ using genetic data for each sample year, and document the ratio of census to effective size.

We report $\mathrm{N}_{\mathrm{e}}$ estimated for the Chiwawa River collections based on the bias correction method of Waples (2006) implemented in LDNe (Do and Waples unpublished). $\mathrm{N}_{\mathrm{e}}$ estimates based on LD are best interpreted as the effective number of breeders $\left(\mathrm{N}_{\mathrm{b}}\right)$ that produced the sample (Waples 2006).

For collections categorized by spawning location (i.e., hatchery broodstock or natural), estimates of $\mathrm{N}_{\mathrm{b}}$ are shown in Table 10. Considering the hatchery broodstock, $\mathrm{N}_{\mathrm{b}}$ estimates range from 30.4 (1996) to 274.3 (2005). To obtain $\mathrm{N}_{\mathrm{e}} / \mathrm{N}$ ratios, the $\mathrm{N}_{\mathrm{b}}$ estimate is multiplied by four (i.e., mean generation length) and divided by the total in river (i.e., NOS [natural-origin spawners] plus HOS [hatchery-origin spawners]) census data from four years prior (i.e., major cohort; see Table 2). The observed $\mathrm{N}_{\mathrm{e}} / \mathrm{N}$ ratios for the broodstock collections range from $11 \%$ to $54 \%$ of the census estimate, excluding the 2000 collection which is $106 \%$. A ratio greater than one is possible under special circumstances, and certain artificial mating schemes within hatcheries can inflate $\mathrm{N}_{\mathrm{e}}$ above N ; yet, it is unknown if this is the case for this collection. While no direct comparisons are possible, the $\mathrm{N}_{\mathrm{b}}$ estimates reported by Williamson et al. (submitted) for Chiwawa broodstock collections from 2000 - 2003 are similar in magnitude to our estimates. For Chiwawa natural spawner collections, the $\mathrm{N}_{\mathrm{b}}$ estimates range from 5.2 (1989) to 231.5 (2005), with observed $\mathrm{N}_{\mathrm{e}} / \mathrm{N}$ ratios of $22 \%-48 \%$ of the census estimate.

## Task 9: Calculate $\mathbf{N}_{\mathrm{b}}$ using the temporal method for multiple samples from the same location.

Estimates of effective number of breeders $\left(\mathrm{N}_{\mathrm{b}}\right)$ derived from Waples' (1990) temporal method are shown in Tables 11-13. Eight collection years were used for the Chiwawa broodstock collections (Table 11). The harmonic mean of all pairwise estimates of $\mathrm{N}_{\mathrm{b}}$ ( $\tilde{\mathrm{N}}_{\mathrm{b}}$ ) was 269.4. This estimate is the contemporary $\mathrm{N}_{\mathrm{e}}$ for Chiwawa broodstock collections. For the five collection years of Chiwawa in-river spawners (Table 12), the estimated $\tilde{\mathrm{N}}_{\mathrm{b}}=224.2$. This estimate is the contemporary $\mathrm{N}_{\mathrm{e}}$ for Chiwawa River natural spawner collections. Since the Chiwawa Supplementation Program is integrated by design, we also performed another estimation of $\mathrm{N}_{\mathrm{e}}$ using composite hatchery and natural samples. There are paired samples from 2004-2006. We combined genetic data for hatchery (HOS) and natural (NOS) origin fish from 2004-2006 to create a single Chiwawa River natural spawner sample for each year. The three composite samples from 2004 - 2006 were then analyzed using the temporal method (Table 13), resulting in a $\tilde{\mathrm{N}}_{\mathrm{b}}$ $=386.8$. This estimate is the contemporary $\mathrm{N}_{\mathrm{e}}$ for Chiwawa River.

Williamson et al. (submitted) estimated $\mathrm{N}_{\mathrm{e}}$ using Waples' (1990) temporal method for Chinook captured in 2004 and 2005, and used age data to decompose brood years into consecutive cohorts from 2000-2003. They report for Chiwawa broodstock a $\tilde{\mathrm{N}}_{\mathrm{b}}=$ 50.4. This estimate is not similar to our Chiwawa broodstock estimate. However, if we analyze the hatchery-origin Chinook only, our estimate is $\widetilde{\mathrm{N}}_{\mathrm{b}}=80.1$ for collection years 1989 - 2006 (data not shown). Williamson et al. (submitted) report for Chiwawa naturally spawning Chinook a $\tilde{\mathrm{N}}_{\mathrm{b}}=242.7$, which is slightly higher than our estimate for in-river spawners from 1989 - 2006, but lower than our estimate from combined NOS and HOS Chinook from 2004-2006 collection years.

## Task 10: Use available data and the Ryman-Laikre and Wang-Ryman models to determine the expected change of $\mathrm{N}_{\mathrm{e}}$ for natural spring Chinook salmon in the Wenatchee River due to hatchery operation.

$\mathrm{N}_{\mathrm{e}}$ is generally thought to be between 0.10 and 0.33 of the estimated census size (Bartley et al. 1992; RS Waples pers. comm.). We used this range to generate an estimate of $\mathrm{N}_{\mathrm{e}}$ for Chiwawa natural spawners prior to hatchery operation. For brood years 1989 - 1992, the arithmetic mean census size was $\mathrm{N}=962.7$ (Table 2), resulting in an estimated $\mathrm{N}_{\mathrm{e}}$ ranging from $96.3-317.7$. The contemporary estimate of $\mathrm{N}_{\mathrm{e}}$ calculated using genetic data for the Chiwawa in-river spawners is $\mathrm{N}_{\mathrm{e}}=224.2$ (Table 12), falling in the middle of the pre-hatchery range. The $\mathrm{N}_{\mathrm{e}} / \mathrm{N}$ ratio calculated using 224.2 and the arithmetic census of NOS Chinook from 1989 - 2005 is 0.42 . A more appropriate contemporary $\mathrm{N}_{\mathrm{e}}$ to compare with the pre-hatchery estimate (i.e., $96.3-317.7$ ) is the combined NOS and HOS estimate from natural spawners, since the supplementation program is integrated. As discussed above, the contemporary estimate of $\mathrm{N}_{\mathrm{e}}$ calculated using genetic data for Chiwawa NOS and HOS Chinook is $\mathrm{N}_{\mathrm{e}}=386.8$ (Table 13), which is slightly larger than the pre-hatchery range, suggesting the $\mathrm{N}_{\mathrm{e}}$ has not declined during the period of hatchery operation. The $\mathrm{N}_{\mathrm{e}} / \mathrm{N}$ ratio calculated using 386.8 and the arithmetic census of NOS and HOS Chinook from 1989 - 2005 is 0.40 . These results suggest the Chiwawa Hatchery Supplementation Program has not resulted in a smaller $\mathrm{N}_{\mathrm{e}}$ for the natural spawners from the Chiwawa River.

Williamson et al. (submitted) argued that since their combined (i.e., broodstock and natural) $\mathrm{N}_{\mathrm{e}}$ estimate was lower than the naturally spawning estimate, the supplementation program likely had a negative impact on the Chiwawa River $\mathrm{N}_{\mathrm{e}}$. We disagree with this interpretation of these data. Since the natural spawning component is mixed hatchery and natural ancestry, the $\mathrm{N}_{\mathrm{e}}$ estimates from natural spawning data are the results that bear on possible hatchery impacts. The census data show the population declined in the mid 1990's and rebounded by 2000 (Table 2). This trend is reflected in the $\mathrm{N}_{\mathrm{e}}$ results, as shown above, and Williamson et al. (submitted) clearly show in their Table 4 the $\mathrm{N}_{\mathrm{e}}$ was lower in $2000\left(\mathrm{~N}_{\mathrm{e}}=989\right)$ than it was in $1992\left(\mathrm{~N}_{\mathrm{e}}=2683\right)$. Yet, the important comparison
they make in our view was the natural spawning $\mathrm{N}_{\mathrm{e}}$ versus the natural only component $\mathrm{N}_{\mathrm{e}}$ (i.e., hypothetically excluding hatchery program). Williamson et al. (submitted) report the 1989 - $1992 \mathrm{~N}_{\mathrm{e}}$ estimated from naturally spawning Chinook (i.e., NOS and HOS integrated) was essentially the same as the natural only component estimate, 2683 and 2776, respectively. This result is not surprising since no HOS fish were present between 1989 - 1992. They also report that the $1997-2000 \mathrm{~N}_{\mathrm{e}}$ estimated from naturally spawning Chinook (i.e., NOS and HOS integrated) was $\mathrm{N}_{\mathrm{e}}=989$, while the natural-origin estimate of $\mathrm{N}_{\mathrm{e}}$ in $1997-2000$ was $\mathrm{N}_{\mathrm{e}}=629$. Since the natural-origin estimate of 629 is lower than 989 , the $\mathrm{N}_{\mathrm{e}}$ estimate from all in-river spawners, we argue that their analysis of demographic data show the $\mathrm{N}_{\mathrm{e}}$ estimated from naturally spawning Chinook (i.e., NOS and HOS integrated) is larger only if the hatchery Chinook in the river are ignored.

## Task 11: Use individual assignment methods to determine the power of self-assignment for upper Wenatchee River tributaries.

See "Assignment of Individual to Populations" in Task 6

## Conclusions

Has the Chiwawa Hatchery Supplementation Program succeeded at increasing the census size of the target population while leaving genetic integrity intact? This is an important question, as hatcheries can impact natural populations by reducing overall genetic diversity (Ryman and Laikre 1991), reducing the fitness of the natural populations through relaxation of selection or inadvertent positive selection of traits advantageous in the hatchery (Ford 2002; Lynch and O’Hely 2001), and by reducing the reproductive success of natural populations (McLean et al. 2003). The census data presented here show that the current natural spawning census size is similar to the pre-supplementation census size. Despite large numbers of hatchery-origin fish on the Chiwawa River spawning grounds, the genetic diversity of the natural-origin collections appear unaffected by the supplementation program; heterozygosities are high, and contemporary $\mathrm{N}_{\mathrm{e}}$ is similar (perhaps slightly higher) than pre-supplementation $\mathrm{N}_{\mathrm{e}}$. We did find
significant year-to-year differences in allele frequencies in both the origin and spawner datasets, but these differences do not appear to be related to fish origin, spawning area, or genetic drift. However, we do suggest that cohort differences may be the most important factor accounting for differences in allele frequencies among collections.

The main objective of this study was to determine the potential impacts of the hatchery program on natural spring Chinook in the upper Wenatchee system. We did this by analyzing temporally replicated collections from the Chiwawa River, and by comparing genetic diversity prior to the presumed effect of the Chiwawa Hatchery Supplementation Program, with contemporary collections. We report that the genetic diversity present in the Chiwawa River is unchanged (allowing for differences among cohorts) from 1989 2006, and the contemporary estimate of the effective population size $\left(\mathrm{N}_{\mathrm{e}}\right)$ using genetic data is approximately the same as the $\mathrm{N}_{\mathrm{e}}$ estimate extrapolated from 1989-1992 census data (i.e., pre-hatchery collection years). We observed substantial genetic diversity, with heterozygosities $\sim 80 \%$ over thirteen microsatellite markers. Yet, temporal variation in allele frequencies was the norm among temporal collections from the same populations (i.e., location). The genetic differentiation of replicated collections from the same population is likely the result of salmon life history in this area, as four-year-old Chinook comprise a majority of returns each year. The genetic tests are detecting the differences of contributing parents for each cohort. An important point related to the temporal variation, is that the hatchery broodstock is composed in part of the natural origin Chinook from the Chiwawa River. When we compared the genetic data (within a collection year) for Chinook brought into the hatchery as broodstock with the Chinook that remained in the river (years 2001, 2004 - 2006), there was a trend of decreasing statistical differences in allele frequencies from 2001 to 2004, and no differences were detected for 2005 and 2006. While the replicated collections may have detectable differences in allele frequencies, those differences reflect actual differences in cohorts, not the result of hatchery operations, and the hatchery broodstock collection method captures the differences in returning Chiwawa River spring adults each year. We conclude from these results that the genetic diversity of natural spring Chiwawa Chinook has been maintained during the Chiwawa Hatchery Supplementation Program.

We observe slight, but statistically significant population differentiation between Chiwawa River, White River, and Nason Creek collections. Murdoch et al (2006) and Williamson et al. (submitted) also observed population differentiation between Chiwawa River, White River, and Nason Creek collections. Yet, $99.3 \%$ of the genetic variation observed was within samples, very little variance could be attributed to population differences (i.e., population structure). The AMOVA analysis and poor individual assignment results suggest the occurrence of gene flow among Wenatchee River locations or a very recent divergence of these groups. While Murdoch et al. 2006 did not perform an AMOVA analysis, their $\mathrm{F}_{\text {ST }}$ results provide comparable data to our amongpopulation results. Murdoch et al. 2006 report $\mathrm{F}_{\text {ST }}$ ranging from $2 \%-3 \%$ for pairwise comparisons between of Chiwawa, White, and Nason River collections. Since FST is an estimate of among-sample variance, these results also imply a majority of the genetic variance (i.e., $97 \%-98 \%$ ) resides within collections. To provide further context for the magnitude of these variance estimates, we present the among-group data from Murdoch et al. 2006 comparing summer-run and spring-run Chinook from the Wenatchee River. They report that approximately $91 \%$ of observed genetic variance is within-collection for comparisons between collections of summer- and spring-run Chinook. Ultimately, the information provided by this and other reports will be incorporated into the management process for Wenatchee River Chinook. However, we would like to emphasize that the application of these genetic data to management is more about the goals related to the distribution of genetic diversity in the future than specific data values reported. If Chinook are collected at Tumwater Dam instead of within the upper Wenatchee River tributaries, a vast majority of the genetic variation present in the basin would be captured, although any differences among tributaries would be mixed. Alternatively, management policies could be crafted to promote and maintain the among-group genetic diversity that genetic studies consistently observe to be non-zero within the Wenatchee River.

We agree with Murdoch et al. (2006) that it appears hatchery Chinook are not contributing to reproduction in proportion to their abundance. Additionally, if the total census size (i.e., NOS and HOS combined) within the Chiwawa River does not continue
to increase, genetic diversity may decline within this system, given the smaller $\mathrm{N}_{\mathrm{e}}$ within the hatchery-origin collections compared with the natural-origin collections.

## Acknowledgements

We would like to thank Denise Hawkins, Craig Busack, and Cheryl Dean for helpful comments regarding this project. This project was funded by Chelan County PUD and the Washington State General Fund.

Figure 1. Conceptual process for evaluating potential changes in genetic variation in the Chiwawa naturally produced populations as a result of the supplementation hatchery programs (From Murdoch and Peven 2005).

Figure 2. Multidimensional scaling plot from an allele-sharing distance matrix calculated from the Chiwawa data set organized by fish origin (i.e., hatchery versus natural). The red arrows connect consecutive hatchery-origin collections starting with the first adult collection (1996) and ending with the 2006 collection (see Table 1 for collection years).

Figure 3. Relationships between the time interval in years and allele sharing distances, with each circle representing the pairwise relationship between two Chiwawa collections. Separate regression lines for the natural- and hatchery-origin collections. The slope for the natural-origin collection is not significantly different from zero ( $\mathrm{p}=0.1483$ ), while the slope for hatchery-origin collection is significantly greater than zero ( $\mathrm{p}=0.0254$ ) indicating a positive relationship between time interval and allele sharing distance.

Figure 4. Multidimensional scaling plot from an allele-sharing distance matrix calculated from the Chiwawa data set organized by four treatment groups, as discussed in the text. Each circle represents a single collection within each of the four treatment groups, and the polygon encloses all groups that are not outliers. Each outlier group is specifically labeled.

Figure 5. As in Figure 4, but allele-sharing distance matrix recalculated without the five outlier groups shown in Figure 4. Polygons group together treatment groups from the same collection year. Dates associated with symbols also refer to collection year. Collection years 2004-2006 included all four treatment groups, while collection year 2001 did not include a hatchery-origin natural spawner group. Legend is read as follows: Open circles refer to hatchery-origin hatchery spawner group, while filled box refers to natural-origin hatchery spawner group, and so on.

(5.3\%)

Figure 6. Principal component (PC) analysis of individual fish from the Chiwawa River. Only fish with complete microsatellite genotypes were included in the analysis ( $\mathrm{n}=757$ ). Open circles are the PC scores for individual fish, and the filled circles are the centroids (bivariate means) for each of the 25 groups discussed in the text. PC axes 1 and 2 account for only $10.5 \%$ of the total molecular variance.

Figure 7. Multidimensional scaling plot from an allele-sharing distance matrix calculated from the Chiwawa origin data set and all other non-Chiwawa collections, except Little Wenatchee River. Legend is read with abbreviations beginning with origin and then spawning location. $\mathrm{H}=$ hatchery, $\mathrm{N}=$ natural, and $\mathrm{S}=$ smolts. Polygons with solid lines enclose the naturalorigin natural spawner collections from each population (i.e., river). The polygon with the dotted lines enclose all Chiwawa collections, except for the five outlier collections, as discussed in text.

Table 1 Summary of within population genetic data. Chiwawa collection data are summarized in A) by origin of the sample (i.e., clipped vs. non-clipped). All collection data are summarized in B) by spawning location (i.e., hatchery broodstock or on spawning grounds). Hz is heterozygosity, HWE is the statistical significance of deviations from Hardy-Weinberg expectations $\left(*=0.05,{ }^{* *}=0.01\right.$, and $* * *=0.001$ ), LD is the proportion of pairwise locus tests (across all populations) exhibiting linkage disequilibrium (bolded values are statistically significant), and the last column is mean number of alleles per locus.

Table 2 Demographic data for Chiwawa Hatchery and Chiwawa natural spring Chinook salmon. BS is census size of hatchery broodstock, pNOB is the proportion of hatchery broodstock of natural origin, NOS is the census size of natural-origin spawners present in Chiwawa River, HOS is the census size of hatchery-origin spawners present in Chiwawa River, Total is NOS and HOS combined, and pNOS is the proportion of spawners present in Chiwawa River of natural origin.

| Brood Year | Hatchery |  | In River |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

Table 3 Levels of significance for pairwise tests of genic differentiation among all hatchery- and natural-origin collections used in this analysis. HS = highly significant ( $\mathrm{P}<0.000095$; the Bonferroni corrected p-value for an alpha $=0.05$ ); * $=\mathrm{P}<0.05$ (nominal critical value for most statistical test); - = P>0.05 (not significant). A significant result between pairs of populations indicates that the allele frequencies between the pair are significantly different. Results are read by comparing the collections along the rows to collections along columns. The top block for each section is a symmetric matrix, as it compares collections within the same group.

Table 4 Probabilities (above diagonal) and levels of significance (below diagonal) for pairwise tests of genic differentiation among all Chiwawa hatchery broodstock and Chiwawa natural spawner collections used in this analysis. HS = highly significant ( $\mathrm{P}<0.000476$; the Bonferroni corrected pvalue for an alpha $=0.05$ ); * $=\mathrm{P}<0.05$ (nominal critical value for most statistical test); $-=\mathrm{P}>0.05$ (considered not significant). A significant result between pairs of populations indicates that the allele frequencies between the pair are significantly different. Pairwise comparisons between the hatchery broodstock and natural spawner collections from 2001, 2004, 2005, and 2006, respectively, are highlighted.

Table 5 Analysis of molecular variance (AMOVA) for the Chiwawa collections, showing the partition of molecular variance into (1) within collections, (2) among collections but within group, and (3) among group components. Each column in the table represents a separate analysis testing for differences under a different spatial or temporal hypothesis. The different analyses are grouped together in a single table for comparisons. The values within the table are percentages and the parenthetical values are P -values, or probabilities, associated with that percentage. P values greater than 0.05 indicate that the percentage is not significantly different from zero. For example, when collections are organized by hatchery- versus natural-origin ("Origin" - fourth column), $0.11 \%$ of the molecular variance is attributed to among group (i.e., hatchery- versus natural-origin), which is not significantly different from zero. No collections (first column) indicates no organization or grouping among all collections, and the among-group percentage is equal to the $\mathrm{F}_{\text {ST }}$ for the entire data set.

|  | No Structure | Collection <br> Year | Spawning <br> Location | Origin | Origin- <br> Spawning <br> Location |
| :--- | :---: | :---: | :---: | :---: | :---: |

|  | $(0.00)$ | $(0.00)$ | $(0.00)$ | $(0.00)$ | $(0.00)$ |

Table $6 \mathrm{~F}_{\text {ST }}$ values for all pairwise combinations of populations. Each $\mathrm{F}_{\text {ST }}$ is the median value for all pairwise combinations of collections within each population (the number of collections within each population is shown parenthetically next to each population name on each row). For example, the FST for the Chiwawa hatchery versus the White River (0.019) is the median value of 54 pairwise comparisons. The bold values along the center diagonal are the median $\mathrm{F}_{\text {ST }}$ values within each collection. For those populations with only one collection, the diagonal value was set at 0.000 .

Table 8 Individual assignment results reported are the numbers of individuals assigned to each population using the partial Bayesian criteria of Rannala and Mountain (1997) and a "jack-knife" procedure (see Methods). The population with the highest posterior probability is considered the stock of origin (i.e., no unassigned individuals). Individuals from each population are assigned to specific populations (along rows). Bold values indicate correct assignment back to population of origin. Individuals assigned to a population are read down columns. For example, of the 595 individuals from Chiwawa hatchery origin, 134 individuals were assigned to Chiwawa natural origin (reading across). Of the 511 individuals assigned to Chiwawa natural origin (reading down), 60 were from Nason Creek.

| Population | Total | Unassigned | $\mathbf{1}$ | $\mathbf{2}$ | $\mathbf{3}$ | $\mathbf{4}$ | $\mathbf{5}$ | $\mathbf{6}$ | $\mathbf{7}$ | $\mathbf{8}$ |

Project No. 1996-040-00

#### Abstract

In 2016, Yakama Nation Fisheries Resource Management (YNFRM) monitored emigration of Endangered Species Act (ESA) listed Upper Columbia River (UCR) spring Chinook salmon and summer steelhead as well as naturally spawned juvenile coho salmon in Nason Creek. This report summarizes juvenile abundance and freshwater survival estimates for each of these species. Fish were captured using a 1.5 m rotary smolt trap between March 1 and November 30, 2016. We collected 852 spring Chinook salmon, 672 summer steelhead, 1 bull trout, and 6 coho; all of natural origin and varying age classes. Daily fish abundances for spring Chinook, steelhead, and coho were expanded by stream discharge-to-trap efficiency regression or pooled estimates. All estimates were made with a $95 \%$ confidence interval (CI) with total emigration estimates for BY2014 spring Chinook juveniles and coho juveniles of $8,694( \pm 5,207)$ and $223( \pm$ 514), respectively. We estimated the total BY2013 summer steelhead emigration at the trap to be 13,417 ( $\pm 3,733$ ). Egg-to-emigrant survival rates for BY2014 spring Chinook and BY2013 summer steelhead were both $1.7 \%$. Productivity, as measured by emigrants-per-redd, for spring Chinook and summer steelhead, was 76 and 99, respectively.

## ACKNOWLEDGEMENTS

This project is part of a basin-wide monitoring program requiring close coordination between multiple agencies and contractors. We greatly appreciate the hard work of the Yakama Nation Fisheries Resource Management (YNFRM) crew members including Matthew Clubb, Jamie Hallman, Arlene Heemsah, Tim Jeffris, and Kevin Swager who maintained and operated the trap during all hours including nights/weekends and through challenging weather conditions. We would like to also thank the Wenatchee River Ranger District (U.S. Forest Service) and Mr. Duane Bolser for providing use of the trapping site and accommodating the needs of this project as well as to Peter Graf (Grant County PUD) for administering contracting and funding. Finally, thank you to Mike Hughes, Mclain Johnson, Andrew Murdoch, Ben Truscott, and Joshua Williams (Washington Department of Fish and Wildlife), and Tracy Hillman (Bio Analysts, Inc.) for shared data and smolt trap methodologies.

### 1.0 INTRODUCTION

Beginning in the fall of 2004, Yakama Nation Fisheries Resource Management (YNFRM) began operating a rotary smolt trap in Nason Creek for nine months per year. Prior to 2004, the smolt trap was operated on a limited basis solely for hatchery coho predation studies. This project is a cost share between the YNFRM's Mid-Columbia Coho Reintroduction Program (MCCRP) and Grant County PUD's Hatchery Monitoring Plan. Trap operations were conducted in compliance with ESA consultation specifically to address abundance and productivity of spring Chinook, steelhead trout, and coho salmon in Nason Creek.

Within this document we will report:

1) Juvenile abundance and productivity of spring Chinook salmon (tkwínat)

Oncorhynchus tshawytscha, steelhead trout (shúshaynsh) Oncorhynchus mykiss and coho salmon (súnx) Oncorhynchus kisutch in Nason Creek.
2) Emigration timing of spring Chinook salmon, steelhead trout and coho salmon emigrating from Nason Creek.

The data presented will be directly used to address Objective 2 in the Monitoring and Evaluation Plan for PUD Hatchery Programs (Hillman et al. 2015) on a 5-year analytic cycle:

## Objective 2: Determine if the proportion of hatchery fish on the spawning grounds affects the freshwater productivity of supplemented stocks (Hillman et al. 2013).

### 1.1 Watershed Description

The Nason Creek watershed drains 26,547 ha of alpine glaciated landscape where high precipitation and moderate rain on snow recurrence controls the hydrology and aquatic communities. Nason Creek originates near the Cascade crest at Stevens Pass and flows east for approximately 37 river kilometers (rkm) until joining the Wenatchee River at rkm 86.3 just below Lake Wenatchee. Both smolt trap locations employed in 2014 (see section 2.1 Trapping Equipment and Operations) were downstream from the majority of spring Chinook and steelhead spawning grounds (Figure 1). There are 26.4 rkm along the mainstem accessible to anadromous fish in Nason Creek. Private land ownership comprises 21,165 ha ( $79.7 \%$ ) of the watershed while 5,180 ha ( $19.5 \%$ ) are federal and 194 ha ( $0.1 \%$ ) are state owned (USFS et al. 1996).

The channel morphology of the lower 25 rkm of Nason Creek has been impacted by development of highways, railroads, power lines, and residential development resulting in channel confinement and reduced side-channel habitat. The present condition is a low gradient (< $1.1 \%$ ), low sinuosity ( $1: 2$ to 2:0 channel-to-valley length ratio) and depositional channel (USFS et al. 1996). Peak runoff typically occurs in May and June with occasional high water produced by rain on snow events in October and November.

In 2016, mean daily discharge for Nason Creek was $11.1 \mathrm{~m}^{3} / \mathrm{s}$ ( 392 cfs ; Figure 2). The onset of spring freshets was unseasonable early in 2016, with peak flows occurring approximately one
month earlier than the 12-year mean. Accordingly, this resulted in a prolonged summer baseflow period, as snowpack was deminished at a much faster rate than normal. Fall freshets began in mid-October with a significant spike in flow, followed by normal levels of discharge. Water temperature data for 2016 was not available through Washington State Deportment of Ecology (WDOE).

Figure 2. Mean daily stream discharge at the Nason Creek WDOE stream monitoring station in 2016.

### 2.0 METHODS

### 2.1 Trapping Equipment and Operation

The smolt trap was operated continually 24 hours per day, 7 days per week when conditions permitted. During spring snowmelt, operations occurred only during hours of darkness in order to minimize trap damage and capture mortality, while retaining the ability to sample during periods of peak fish movement. Without the threat of vandalism posed during periods of peak use at the previously-used campground location, summer operations at the Bolser location were not modified (daytime suspension).

On a daily basis, fish were removed from the primary collection box and retained in separate shore-anchored holding boxes until removed for efficiencies trials. A rotating drum-screen constantly removed small debris from the live box to avoid fish injury. All changes/modifications to the trap as well as periods of stoppage were noted.

### 2.2 Biological Sampling

Trap operating procedures and techniques followed a standardized basin-wide monitoring plan developed by the Upper Columbia Regional Technical Team (RTT) for the Upper Columbia

Salmon Recovery Board (UCSRB; Hillman 2004), which was adapted from Murdoch and Petersen (2000).

All fish were enumerated by species and size class. Fish to be sampled were anesthetized in a solution of MS-222, weighed with an electronic scale and measured in a wetted trough-type measuring board. Anesthetized fish received air through aquarium bubblers and were allowed to fully recover before being either released downstream of the trap or used in efficiency trials. Fork length (FL) and weight were recorded for all fish except when large numbers of fry or nontarget species were collected; a sub-sample of 25 fish were measured and weighed while the remaining fish were tallied. Weight was measured to the nearest 0.1 gram and FL to the nearest millimeter. We used these data to calculate a Fulton-type condition factor (K-factor) using the formula:

$$
K=\left(W / L^{3}\right) \times 100,000
$$

where $K=$ Fulton-type condition metric;
$W=$ weight in grams;
$L=$ fork length in millimeters;
And 100,000 is a scaling constant.
Scale samples were collected from steelhead measuring $\geq 60 \mathrm{~mm}$ FL so that age and brood year could be assigned. Samples were collected according to the needs and protocols set by Washington Department of Fish and Wildlife (WDFW), who conducted the analysis and provided YNFRM with results. Tissue samples were collected from spring Chinook and steelhead for DNA analysis. Samples from spring Chinook and steelhead were retained for reproductive success analyses conducted by WDFW and National Marine Fisheries Service (NMFS). All target salmonids were classified as either natural or hatchery origin by physical appearance, presence/absence of coded wire tags (CWTs), or post-orbital elastomer tags. Developmental stages were visually classified as fry, parr, transitional, or smolt. Fry were defined as newly emerged fish with or without a visible yolk sac and a FL measuring < 50 mm . Age- 0 coho and spring Chinook salmon captured before July 1 were considered 'fry' and were excluded from subyearling population estimates because of the uncertainity that these fish were actively migrating (UCRTT, 2001).

### 2.3 PIT Tagging

All natural origin Chinook, steelhead and coho measuring $\geq 60 \mathrm{~mm}$ were PIT tagged. Once anesthetized, each fish was examined for external wounds or descaling, then scanned for the presence of a previously implanted PIT tag. If a tag was not detected, a pre-loaded 12 mm Digital Angel 134.2 kHz type TX 1411ST PIT tag was inserted into the body cavity using a Biomark MK-25 Rapid Implant Gun. Each unique tag code was electronically recorded along with date of tag implantation, date of fish release, tagging personnel, FL, weight, and anesthetic bath temperature. Data were entered using P3 software and submitted to the PIT Tag Information System (PTAGIS). PIT tagging methods were consistent with methodologies
described in the PIT Tag Marking Procedures Manual (CBFWA 1999) as well as in 2008 ISEMP protocols (Tussing 2008).

After marking and sampling, fish were held for a minimum of 24-hours in holding boxes at the trap to; a) ensure complete recovery, b) assess tagging mortality, and c) determine a PIT tag shed rate. Mark groups were released by hand 0.8 rkm above the trap at nautical twilight. At each release, fish were distributed evenly along river-left, and river-right banks in pools and other protected areas. Fish that were not used in mark-recapture trials were released downstream from the trap.

### 2.4 Mark-Recapture Trials

Groups of marked juveniles were released during a range of stream discharges in order to determine the trapping efficiency. PIT tags were the only method of marking used in 2016. These releases followed the protocols described in Hillman (2004), in which the author suggests a minimum sample size of 100 fish for each mark-recapture trial. Although 100 fish/trial represented the ideal mark group, low abundance of fish often required mark-recapture trials be completed with smaller sample sizes. To achieve the largest marked group possible, we combined catch over a maximum of 72 hours. Fish being held for mark-recapture trials were kept in auxiliary live boxes attached to the end of each pontoon or floating holding boxed anchored to the stream bank. A pre-season, minimum mark group size for each species/life stage was initially determined based on past regression models. In light of high abundance, minimum trial sizes could be raised to a more robust mark group with the intention of strengthening existing regression models.

Each mark-recapture trial was conducted over a three-day (72 hour) period to allow time for passage or capture. Completed trials were only considered invalid if an interruption to trapping occurred or proper pre-release procedures were not followed. Trials resulting in zero recaptures were included in the efficiency regression (if determined valid once vetted through release/recapture protocols) as allowed by the new method of observed trap efficiency calculation. The model used (Bailey) employs use of recaptures +1 in the calculation of efficiency as a mode of bias correction. As a result, even trials yeilding no recaptures can be included in regression modeling (See equation 3 in 2.5.1 Estimate of Abundance).

In the event that low juvenile abundaces could not provide any opportunities for efficiency trials, releases were performed to allow for a pooled estimate. These releases did not have a minimum size and were released at equal intervals across the migratory period. Pooled estimates at the Nason Creek trap were utilized as an alternative method of estimation prior to the development of a viable regression model.

### 2.5 Data Analysis

### 2.5.1 Estimate of Abundance During Smolt Trapping

Seasonal juvenile migration, N , was estimated as the sum of daily migrations, $N_{i}$, i.e., $N=\sum_{i} N_{i}$, and daily migration was calculated from catch and efficiency:

$$
\begin{equation*}
\hat{N}_{i}=\frac{C_{i}}{\hat{e}_{i}}, \tag{1}
\end{equation*}
$$

where $C_{i}=$ number of fish caught in period $I$;
$\hat{e}_{i}=$ trap efficiency estimated from the flow-efficiency relationship, $\sin ^{2}\left(b_{0}+b_{1}\right.$ flow $\left.{ }_{i}\right)$,
where $b_{0}$ is estimated intercept and $b_{1}$ is the estimated slope of the regression.
The regression parameters $b_{0}$ and $b_{1}$ are estimated using linear regression for the model:

$$
\begin{equation*}
\arcsin \left(\sqrt{e_{k}^{\text {obs }}}\right)=\beta_{0}+\beta_{1} \text { flow }_{k}+\varepsilon \tag{2}
\end{equation*}
$$

where $e_{k}^{\text {obs }}=$ observed trap efficiency of Eq. 2 for trapping period $k$;
$\beta_{0}=$ intercept of the regression model;
$\beta_{1}=$ slope parameter;
$\varepsilon=$ error with mean 0 and variance $\sigma^{2}$.
In Equation 2, the observed trap efficiency, $e_{k}^{\text {obs }}$, is calculated as follows,

$$
\begin{equation*}
e_{k}^{o b s}=\frac{r_{k}+1}{m} . \tag{3}
\end{equation*}
$$

The estimated variance of seasonal migration is calculated from daily estimates as:

$$
\operatorname{Var}\left(\sum_{i=1}^{n} \hat{N}_{i}\right)=\underbrace{\sum_{i} \operatorname{Var}\left(N_{i}\right)}_{\text {Part A }}+\underbrace{\sum_{i} \sum_{j} \operatorname{Cov}\left(N_{i}, N_{j}\right)}_{\text {Part B }},
$$

or,

$$
\begin{equation*}
\operatorname{Var}\left(\sum_{i=1}^{n} \hat{N}_{i}\right)=\underbrace{\sum_{i} \operatorname{Var}\left(\frac{\left(C_{i}+1\right)}{\hat{e}_{i}}\right)}_{\text {Part A }}+\underbrace{\sum_{i} \sum_{j} \operatorname{Cov}\left(\frac{\left(C_{i}+1\right)}{\hat{e}_{i}}, \frac{\left(C_{j}+1\right)}{\hat{e}_{j}}\right)}_{\text {Part B }} . \tag{4}
\end{equation*}
$$

Part A of equation 4 is the variance of daily estimates. Part B is the between-day covariance. Note that the between-day covariance exists only for days that use the same trap efficiency
model. If, for example, day 1 is estimated with one trap efficiency model, and day 2 estimated from a different model, then there is no covariance between day 1 and day 2 . The full expression for the estimated variance:

$$
\begin{aligned}
\operatorname{Var}\left(\sum_{i=1}^{n} \hat{N}_{i}\right)= & \underbrace{\sum_{i} \hat{N}_{i}^{2}\left(\frac{N_{i} \hat{e}_{i}\left(1-\hat{e}_{i}\right)}{\left(C_{i}+1\right)^{2}}+\frac{4\left(1-\hat{e}_{i}\right)}{\hat{e}_{i}} \operatorname{Var}\left(b_{0}+b_{1} \text { flow }_{i}\right)\right)}_{\text {PartA }}+ \\
& \underbrace{\sum_{i} \sum_{j} 4\left(\hat{N}_{i}\left(1-\hat{e}_{i}\right)\right)\left(\hat{N}_{j}\left(1-\hat{e}_{j}\right)\right) \cdot\left[\operatorname{Var}\left(b_{0}\right)+\text { flow }_{i} \text { flow }_{j} \hat{\left.\operatorname{Var}\left(b_{1}\right)\right]}\right.}_{\text {PartB }}
\end{aligned}
$$

where $\operatorname{Var}\left(b_{0}+b_{1}\right.$ flow $\left._{i}\right)=\operatorname{MS} \hat{S}\left(1+\frac{1}{n}+\frac{\left(\text { flow }_{i}-\overline{\text { flow }^{\prime}}\right)^{2}}{(n-1) s_{\text {flow }}^{2}}\right)$, and $\hat{\operatorname{Var}}\left(b_{0}\right)$ and $\hat{\operatorname{Var}}\left(b_{1}\right)$ are
obtained from regression results. In Excel, the standard error (SE) of the coefficients is provided. The variance is calculated as the square of the standard error, $S E^{2}$.

In cases when there was no significant flow-efficiency relationship (i.e., low correlation), then a pooled, or average trap efficiency will suffice for the stratum. The estimator is calculated as follows:

$$
\hat{\bar{e}}=\frac{\sum_{j=1}^{k} r_{j}}{\sum_{j=1}^{k} m_{j}}
$$

where $\hat{\bar{e}}=$ the average or pooled trap efficiency for the stratum;
$m_{j}=$ the number of smolts marked and released in efficiency trial $j$ for the stratum;
$r_{j}=$ the number of smolts recaptured out of $m_{j}$ marked fish in efficiency trial $j$.
Abundance for a trapping period is estimated as:

$$
\hat{N}_{i}^{\text {pooled }}=\frac{C_{i}}{\hat{\bar{e}}},
$$

,and total stratum abundance is:

$$
N^{\text {pooled }}=\sum_{i} \hat{N}_{i}^{\text {pooled }} .
$$

The variance of seasonal abundance takes into account the variability in catch numbers that are a result of binomial sampling (Part A), the pooled variance of trap efficiency, $\hat{\bar{e}}$ (Part B), and the covariance in daily estimates that arises from using a common estimate of efficiency across all trapping days (Part C):

$$
\operatorname{Var}\left(\sum_{i=1}^{n} \hat{N}_{i}^{\text {pooled }}\right)=\underbrace{\left(\sum_{i} \frac{\hat{N}_{i}(1-\hat{\bar{e}})}{\hat{\bar{e}}}\right)}_{\text {PartA }}+\underbrace{\frac{\operatorname{Var}(\hat{\bar{e}})}{\hat{\bar{e}}^{2}} \sum_{i} \hat{N}_{i}^{2}}_{\text {PartB }}+\underbrace{\frac{\operatorname{Var}(\hat{\bar{e}})}{\hat{\bar{e}}^{2}} \sum_{i} \sum_{j} \hat{N}_{i} \hat{N}_{j}}_{\text {PartC }} .
$$

The Part B and Part C terms are combined in the calculation as a new Part B:

$$
\operatorname{Var}\left(\sum_{i=1}^{n} \hat{N}_{i}^{\text {pooled }}\right)=\underbrace{\left(\sum_{i} \frac{\hat{N}_{i}(1-\hat{\bar{e}})}{\hat{\bar{e}}}\right)}_{\text {PartA }}+\underbrace{\frac{\operatorname{Var}(\hat{\bar{e}})}{\hat{\bar{e}}^{2}}\left[\sum_{i} \hat{N}_{i}^{2}+\sum_{i} \sum_{j} \hat{N}_{i} \hat{N}_{j}\right]}_{\text {PartB }} .
$$

The variance of $\hat{e}$ is calculated as:

$$
\operatorname{Vâr}(\hat{\bar{e}})=\operatorname{Vâr}\left(\frac{\sum_{k=1}^{n} r_{k}}{\sum_{k=1}^{n} m_{k}}\right)=\frac{\sum_{k=1}^{n}\left(r_{k}-\hat{e}_{k} m_{k}\right)^{2}}{\bar{m}^{2} n(n-1)}
$$

where $\bar{m}$ is the average release size across all efficiency trial, $\frac{\sum_{k=1}^{n} m_{k}}{n}$.
Confidence intervals were calculated using the following formulas:

$$
95 \% \text { confidence interval }=1.96 \times \sqrt{\sum \operatorname{var}}\left[\hat{N}_{i}\right]
$$

The single M-R estimator of abundance carries a set of well documented assumptions (Everhart and Youngs 1981; Seber 1982),

1. The population is closed to mortality.
2. The probability of capturing a marked or unmarked fish is equal.
3. Marked fish were randomly dispersed in the population prior to recapture.
4. Marking does not affect probabilities of capture.
5. Marks were not lost between the time of release and recapture.
6. All marks are reported upon recapture.
7. The number of fish in the trap, C , is fully enumerated and known without error.

### 2.5.2 Estimate of Abundace During Trap Stoppages and Suspended Operations

Daily catch during stoppages of seven days or less was estimated by averaging catch three days prior to, and after the discreet non-trapping event and then applying that value to the consecutive days without operation. This method had been used consistently in the past given the duration of the stoppage is limited, and is applied to all target species.

For periods of suspended trapping longer than seven days, a methodology developed and currently employed by local WDFW smolt trap operators was used (J. Williams, personal
communication, March 8, 2017). This method uses historic run-timing to determine the proportion of the entire emigrant estimate missed during the period of suspended trapping. Once determined, the estimated percentage can be used with in-year data to extrapolate how many fish were missed. This method is used exclusively during the fall migratory period, when low summer flows commonly result in extended stoppages. Because steelhead are considered nonmigratory during this period, this type of estimate was only applied to spring Chinook subyearlings.

### 2.5.3 Estimate of Abundance During The Winter Non-Trapping Period

An estimate of spring Chinook emmigration during the non-trapping period (December 1 through February 28) was calculated using remote-tagged spring chinook parr and the lower Nason Creek PIT tag array (NAL). A flow-detection efficiency regression was developed using mark-groups previously released to test the efficiency of the smolt trap. Daily spring Chinook detections at the NAL array and the developed regression were then applied to the Bailey estimator, as was peformed with daily trap abundance data (See equation 2.5.1 Estimate of Abundance). Tag rate determined at the Nason Creek smolt trap was used to account for unmarked emmigrants passing the NAL array.

Tag rate, $t_{i}$, was calculated as:

$$
t_{i}=\frac{t}{p}
$$

where $t=$ total smolt trap recaptures subsequent to the tagging effort;
$p=$ total catch at the smolt trap.

Daily abundace during the non-trapping period is calculated as:

$$
\hat{N}_{i}=\left(\frac{C_{i}}{\hat{e}_{i}}\right) / t_{i},
$$

where $C_{i}=$ number of fish caught in period $I$;
$\hat{e}_{i}=$ trap efficiency estimated from the flow-efficiency relationship, $\sin ^{2}\left(b_{0}+b_{1}\right.$ flow $\left.w_{i}\right)$;
$t_{i}=$ tag rate .

### 2.5.4 Production and Survival

Production estimates by age class were summed to produce a total emigration estimate. For spring Chinook and coho, estimates of fall migrant parr were added to subsequent spring smolt estimates to generate a single brood year estimate. For steelhead, a single brood year may require up to three years for emigration from Nason Creek to occur. Pending scale analysis, steelhead captured in 2016 were aged via an age-length histogram built upon previously analyzed scale samples. For all three species, egg-to-emigrant estimates were calculated by
dividing estimated emigrants by approximated egg deposition during a spawning brood (average fecundity used to determine egg deposition derived from WDFW Chiwawa broodstock spawning). The number of emigrants-per-redd for each brood year was calculated by dividing the total emigrant estimate by the number of redds counted during spawning ground surveys.

### 3.0 RESULTS

### 3.1 Dates of Operation

The Nason Creek smolt trap was installed on February 25, and operated in its fixed position for the entirety of the trapping season (March 1 to November 30). Removal of the trap occurred on December 5 . We attempted to run the trap continuously 24 hours a day, 7 days per week. Intentional suspension of trapping activities occurred for two periods in the summer-early fall due to base flows (July 31 - August 8 and August 10 - October 9; Table 1). Pulling of the trap also occurred on October 21 as a precautionary measure during a high-water event.

Table 1. Summary of Nason Creek rotary trap operation.

| Date of Trap Operations | Trap Status | Description | Days |
| :---: | :---: | :---: | :---: |
| March 1 to June 30 | Operating | Continuous data collection | 120 |
|  | Interrupted | Interrupted by debris | 2 |
|  | Pulled | Intentionally pulled due to high flow, low flow, or heavy debris load | 0 |
| July 1 to November 30 | Operating | Continuous data collection | 76 |
|  | Interrupted | Interrupted by debris | 6 |
|  | Pulled | Intentionally pulled due to high flow, low flow, or heavy debris load | 71 |

### 3.2 Daily Captures and Biological Sampling

### 3.2.1 Spring Chinook Yearlings (BY2014)

Between March 1 and June 30, a total of 61 wild Chinook yearlings were captured at the trap (Figure 3). A peak catch of 12 yearling smolts coincided with a secondary spike in discharge occurring in early April. Following this peak, catch dropped substantially with the last emigrating Chinook yearling captured on April 8. Mean FL and weight for Chinook yearlings was $96 \mathrm{~mm}(n=61 ; S D=5.5)$ and $9.0 \mathrm{~g}(n=61 ; S D=1.7$; Table 2$)$, respectively. Tissue samples were collected from 61 fish for an ongoing, parental-based DNA analysis by WDFW. There were no wild spring Chinook mortalities.

Figure 3. Daily catch of BY2014 spring Chinook yearlings with mean daily stream discharge at the Nason Creek rotary trap, March 1 to June 30, 2016.

Table 2. Summary of length and weight sampling of juvenile spring Chinook captured at the Nason Creek rotary trap in 2016.

| Brood Year | Origin/Species/Stage | Fork Length (mm) |  |  | Weight (g) |  |  | K- <br> Factor |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Mean | $n$ | SD | Mean | $n$ | SD |  |
| 2014 | Wild Spring Chinook Yearling Smolt | 96 | 61 | 5.5 | 9.0 | 61 | 1.7 | 1.01 |
| 2015 | Wild Spring Chinook Subyearling Fry | 38 | 285 | 3.0 | 0.5 | 285 | 0.2 | 0.78 |
| 2015 | Wild Spring Chinook Subyearling Parr | 85 | 491 | 12.7 | 6.9 | 490 | 2.5 | 1.07 |
| 2014 | Hatchery Spring Chinook Yearling Smolt | 119 | 87 | 13.5 | 19.6 | 87 | 7.6 | 1.09 |

### 3.2.2 Spring Chinook Subyearlings (BY2015)

A total of 491 wild spring Chinook subyearling parr ( $\mathrm{FL} \geq 50 \mathrm{~mm}$ ) and 300 subyearling fry ( FL $<50 \mathrm{~mm}$ ) were captured in 2016 (Figure 4). The majority of parr movement was documented in late October following the first fall freshets. Mean FL and weight among subyearling parr was $85 \mathrm{~mm}(n=491 ; S D=12.7)$ and $6.9 \mathrm{~g}(n=490 ; S D=2.5)$, respectively. We estimate that an additional 20 Chinook subyearling parr would have been captured during short stoppages ( $\leq 7$ days) had the trap run without interruption. Daily catch estimates were not made during the two periods of suspended trapping; total emmigrant estimates for these two periods will be included in section 3.4.2. Tissue samples were collected from 431 fish for an ongoing, parental-based DNA analysis by WDFW. Six subyearling Chinook (four fry and two parr) mortalities occurred in 2016. All deaths were attributed to trapping.

Figure 4. Daily catch of BY2015 spring Chinook subyearlings with mean daily stream discharge at the Nason Creek rotary trap, July 1 to November 30, 2016.

### 3.2.3 Hatchery Spring Chinook Smolts (BY2014)

In the spring of 2016, 31,651 hatchery spring Chinook smolts were released into Nason Creek. All hatchery spring Chinook were released directly from the Grant County Public Utility District (GCPUD) Nason Creek Acclimation Facility located at rkm17.3. Subsequently, a total of 124 smolts were captured with a mean FL and weight of $119 \mathrm{~mm}(n=87 ; S D=13.5)$ and $19.6 \mathrm{~g}(n=$ $87 ; S D=7.6$ ), respectively (Figure 5). Hatchery spring Chinook were not captured at the smolt trap beyond June 3. There were no mortalities incurred.

Figure 5. Daily catch of BY2014 hatchery spring Chinook smolts with mean daily stream discharge at the Nason Creek rotary trap, March 1 to June 30, 2016.

### 3.2.4 Summer Steelhead

A total of 1,007 wild summer steelhead juveniles were captured throughout the season from March 1 to November 30, with a peak catch of 79 juveniles on August 9 (Figs. 6\&7). We estimated that an additional 6 age- 1 juveniles would have been captured had there been no interruptions to trapping during the migratory period (Mar 1 to July 31). Histogram analysis of known steelhead ages sampled from 2005 to 2014 allowed us to estimate ages of fish captured in 2016 using FL. We estimate that of the total steelhead captured, 702 were young-of-the-year, 285 were age-1, 19 were age-2, and 1 was age- 3 . Subyearling steelhead had a mean FL of 56 mm ( $n=674 ; S D=16.4$ ), and a mean weight of $2.4(n=617 ; S D=1.8)$. The majority of steelhead juveniles captured were age-1 parr emigrating past the trap in spring. Mean FL and weight of age- 1 fish was $87 \mathrm{~mm}(n=278 ; S D=21.5$; Table 3$)$ and $8.3 \mathrm{~g}(n=278 ; S D=5.9)$, respectively. Age- 2 steelhead were caught primarily in the spring, with only two fish being captured after July 31. Mean FL and weight of age-2 fish was $143 \mathrm{~mm}(n=19 ; S D=17.4)$ and $31.1 \mathrm{~g}(n=19 ; S D=$ 9.6), respectively. A single age-3 fish with a FL of 202 mm and weight of 90.1 g was also captured. Scales were taken from a sub-sample ( $n=141$ ) to be used for future age analyses. One mortality was incurred (See 3.6 ESA Compliance).

Figure 7. Daily catch of wild summer steelhead with mean daily stream discharge at the Nason Creek rotary trap, August 1 to November 30, 2016. Estimates of fish passage during trap interruptions are not depicted.

Table 3. Summary of length, weight and condition factor by age class of wild summer steelhead emigrants and hatchery steelhead captured at the Nason Creek rotary trap.

| Brood Year | Origin/Species/Stage | Fork Length (mm) |  |  | Weight (g) |  |  | K- <br> Factor |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Mean | $n$ | SD | Mean | $n$ | SD |  |
| 2016 | Wild Summer Steelhead (Age-0) | 56 | 674 | 16.4 | 2.4 | 617 | 1.8 | 1.02 |
| 2015 | Wild Summer Steelhead (Age-1) | 87 | 278 | 21.5 | 8.3 | 278 | 5.9 | 1.05 |
| 2014 | Wild Summer Steelhead (Age-2) | 143 | 19 | 17.4 | 31.1 | 19 | 9.6 | 1.04 |
| 2013 | Wild Summer Steelhead (Age-3) | 202 | 1 | - | 90.1 | 1 | - | 1.09 |
| 2015 | Hatch. Summer Steelhead Smolt | 175 | 95 | 15.5 | 55.1 | 95 | 16.2 | 0.99 |

### 3.2.5 Hatchery Steelhead Smolts (BY2015)

During April and May, WDFW directly planted a total of 55,105 hatchery summer steelhead smolts into Nason Creek above the smolt trap (M. Babiar, personal communication, February 8, 2017). Subsequently, a total of 98 hatchery steelhead were captured at the smolt trap with a mean FL and weight of $175 \mathrm{~mm}(n=95 ; S D=15.5)$ and $55.1 \mathrm{~g}(n=95 ; S D=16.2)$, respectively (Figure 8). The last hatchery smolt was caught on June 14. Hatchery origin was determined by the presence of coded wire tags (CWT). There were no hatchery-origin steelhead smolt mortalities.
$\longleftarrow$ BY2015 Hatchery Summer Steelhead ——Stream Discharge

Figure 8. Daily catch of BY2015 hatchery steelhead smolt with mean daily stream discharge at the Nason Creek rotary trap, March 1 to June 30, 2016.

### 3.2.6 Bull Trout

Bull trout presence at the trap in 2016 was limited to a single fish with a FL of 199 mm and weight of 70.0 g . The bull trout was released immediately after morphometric measurements were taken. No other sampling/tagging activities were performed.

### 3.2.7 Coho Yearlings (BY2014)

Six naturally-produced coho yearlings were captured during spring emigration between March 1 and June 30 (Figure 9). Their mean FL and weight was $100 \mathrm{~mm}(n=6 ; S D=15.8)$ and $11.1 \mathrm{~g}(n$ $=6 ; S D=5.5$ ), respectively (Table 4). Scale and tissue samples were not taken from naturallyproduced coho smolts in 2016. There were no coho yearling mortalities.

Figure 9. Daily catch of BY2014 naturally-produced coho yearlings with mean daily stream discharge at the Nason Creek rotary trap, March 1 to June 30, 2016.

Table 4. Summary of length and weight sampling of juvenile coho salmon captured at the Nason Creek rotary trap in 2016.

| Brood <br> Year | Origin/Species/Stage | Fork Length (mm) |  |  | Weight (g) |  |  | K- <br> Factor |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Mean | $n$ | SD | Mean | $n$ | SD |  |
| 2013 | Naturally Produced Coho Yearling Smolt | 100 | 6 | 15.8 | 11.1 | 6 | 5.5 | 1.03 |
| 2013 | Hatchery Coho Yearling Smolt | 134 | 302 | 8.4 | 24.8 | 301 | 5.0 | 1.02 |

### 3.2.8 Coho Subyearlings (BY2015)

There were no BY2015 naturally-produced coho fry or parr captured at the Nason Creek smolt trap in 2016.

### 3.2.9 Hatchery Coho Smolts (BY2014)

A total of 276,063 hatchery coho were released into Nason Creek above the trap in spring of 2016. All hatchery coho released were acclimated in natural ponds adjacent to Nason Creek and
reared to smolt stage prior to volitional release. Between March 1 and June 30, a total of 343 hatchery coho were captured at the trap (Figure 10). Mean FL was $134 \mathrm{~mm}(n=302 ; S D=8.4)$ and mean weight was $24.8 \mathrm{~g}(n=301 ; S D=5.0$; Table 2$)$. A peak daily catch of 45 hatchery coho smolts occurred on April 29 following volitional release into Nason Creek. Two trapping mortalities were incurred. Hatchery coho emigration data at the Nason Creek trap assists the MCCRP by providing size-at-emigration, emigration timing and duration of residence in Nason Creek.

Figure 10. Daily catch of BY2014 hatchery coho smolt with mean daily stream discharge at the Nason Creek rotary trap, March 1 to June 30, 2016.

### 3.3 Remote Parr Tagging (BY2014 Spring Chinook)

YNFRM and WDFW personnel PIT tagged and released a total of 1,214 BY2014 spring Chinook parr between September 23 and October 15, 2015. The total surveyed area included Nason Creek from rkm 0.8 to 26.1. All collections were performed via backpack electrofisher. Equal capture effort (measured in electrofisher seconds used) was applied across all reaches.

Between October 1 and March 30, a total of 100 re-sights of the remote tagged spring Chinook were documented at the NAL array (Figure 11). Of these detections, only two were during the winter non-trapping period. High flows in November caused significant damages to the NAL array, resulting in antennas 1,5 , and 6 being inoperable throughout the non-trapping period (J. Deason Personal Communication, February 10, 2016).

Subsequent to the remote tagging effort, five remote-tagged BY2014 spring Chinook were recaptured at the Nason Creek smolt trap. Total spring Chinook catch at the smolt trap was 255 emigrants during the same period. The pooled tag rate for remote-tagged spring Chinook captured at the Nason smolt trap was $2.0 \%$.

Figure 11. Daily detections of remote-tagged BY2014 spring Chinook at the lower Nason Creek PIT tag antenna array (NAL) between October 2015 and March 2016.

### 3.4 Trap Efficiency Calibration and Population Estimates

### 3.4.1 Spring Chinook Yearlings (BY2014)

Infrequent releases, low abundance, and a lack of recaptures did not allow a flow-efficiency model to be used on BY2014 yearling emigrants. In order to produce an estimate, a pooled efficiency ( $6.6 \%$ ) composed of spring Chinook yearling releases in 2016 was used (Table 5). We recognize the sub-optimal nature of this estimation methodology, and will recalculate the estimates using linear regression analysis as soon as feasible. We estimated a total of 930 ( $\pm$ 5,083; 95\% CI) BY2014 spring Chinook yearlings emigrated in spring of 2016 (Table 6). Parr emmigration during the non-trapping period was estimated using a flow-efficiency regression $\left(r^{2}\right.$ $=0.38 ; p=0.007$ ) based on detections at the NAL pit tag array. This antenna efficiency is solely based on detections made on the three antennas that were functional during winter of 2016. We estimated that 1,442 ( $\pm 1,297$; 95\% CI) BY2013 spring Chinook emigrated out of Nason Creek during the non-trapping period. Combined with a recalculated BY2014 subyearling estimate of $8,694( \pm 5,207 ; 95 \%$ CI), we estimated that a total of $7,280( \pm 5,197 ; 95 \%$ CI) BY2014 spring Chinook juveniles emigrated from Nason Creek.

### 3.4.2 Spring Chinook Subyearlings (BY2015)

A linear regression model was developed using subyearling mark groups released in the fall of 2014 and 2016. The resulting regression ( $r^{2}=0.60 ; p=0.005$ ) was based on individual mark groups of $\geq 50$ Chinook subyearlings only. Using this model we estimated that a total of 3,813 ( $\pm 1,116 ; 95 \%$ CI) BY2015 spring Chinook emigrated past the trap in the fall of 2016 (Table 6).

Table 7. Trap efficiency trials conducted with BY2015 wild spring Chinook subyearlings.

| Origin/Species/Stage | Age | Date | Marked | Recaptured | Discharge <br> $\left(\mathrm{m}^{3} / \mathrm{s}\right)$ |

| Total |  |  | $\mathbf{2 9 0}$ | $\mathbf{3 4}$ |  |

### 3.4.3 Summer Steelhead

Low abundance of summer steelhead emigrants in the spring of 2016 required a pooled estimate be used in light of the inability to meet minimum mark-group sizes ( $n=50$ ) for regression analysis. Releases of PIT-tagged steelhead were subsequently released every four days upstream at the established release location (Table 8). In a total of 31 separate trials, 216 wild summer steelhead were released upstream with 3 recaptures (1.4\%). Estimates of age-0 fry and parr were not made due to insufficient evidence that active migration is occurring at this young age. Previous attempts at the old location to build a model based on young-of-the-year steelhead parr in the fall have yielded weak flow-efficiency relationships; further suggesting that age-0 parr catch is the result of displacement rather than active migration. We estimated that 19,872 $( \pm$ 69,909; 95\% CI) BY2015 age-1, 1,124 ( $\pm 4,437 ; 95 \%$ CI) BY2014 age-2, and 72 ( $\pm 294 ; 95 \%$ CI) BY2013 age-3 steelhead emigrated past the trap in 2016 (Table 9). We estimate that total (age 1-3) BY2013 emigration to be $13,417( \pm 9,133 ; 95 \% \mathrm{CI})$. All pooled estimates will be recalculated upon development of a species-specific flow-efficiency model.

### 3.4.4 Coho Yearlings (BY2014)

Limited abundance of BY2014 coho yearlings did not provide any opportunities to perform any efficiency trials in the spring of 2016. In lieu of a species-specific model, a pooled efficiency based on yearling spring Chinook releases was applied to wild coho smolts. In the spring of 2016, we estimated that 92 ( $\pm 504 ; 95 \%$ CI) emigrated past the trap (Table 10). Combined with a subyearling estimate of $131( \pm 96 ; 95 \% \mathrm{CI})$, this gave us a total BY2014 emigrant estimate of 223 ( $\pm 514 ; 95 \% \mathrm{CI})$.

Figure 14. Relationships between estimated egg deposition and total emigrants produced, egg-to-emigrant survival, and emigrants per redd for Nason Creek natural-produced coho, BY 2003 to 2014. *2014 brood (denoted by red border).

### 3.4.5 Coho Subyearlings (BY2015)

Due to lack of BY2015 naturally-produced coho catch, we concluded that there were no emigrants from Nason in 2016.

### 3.5 PIT Tagging

During the 2016 trapping season, we PIT tagged 495 wild spring Chinook, 531 steelhead, and 6 naturally produced coho (Table 11). All tagging files were submitted to the PTAGIS database. One shed PIT tag (implanted in steelhead parr) was recovered in a holding box where fish had been held for 24-72 hours after tagging. During remote tagging efforts in the fall of 2015, 1,214 spring Chinook were PIT tagged by YNFRM and WDFW personnel.

Table 11. Number of PIT tagged coho, Chinook, and steelhead with shed rates at the Nason Creek rotary trap in 2016.

| Species/Stage | Year-to- <br> date Catch | Year-to- <br> date PIT <br> Tagged | No. of <br> Shed Tags | Percent <br> Shed Tags |
| :--- | :---: | :---: | :---: | :---: |

| Coho Yearling Smolt | 6 | 6 | 0 | $0.0 \%$ |
| Coho Subyearling Parr | 0 | 0 | - | - |

* Counts do not include fish with FL<50mm (fry).

### 3.6 Incidental Species

Along with wild spring Chinook, wild steelhead/rainbow trout, and naturally produced coho, other resident fish species captured at the Nason Creek rotary trap and included in Table 12 are: bull trout Salvelinus confluentus, cutthroat trout Oncorhynchus clarki, flathead minnow Pimephales promelas, longnose dace Rhinichthys cataractae, northern pikeminnow Ptychocheilus oregonensis, redside shiner Richardsonius balteatus, sculpin Cottus sp., sucker Catostomus sp., and mountain whitefish Prosopium williamsoni.

Table 12. Summary of length and weight sampling of incidental species captured at the Nason Creek rotary trap in 2016.

| Species | Total Count | Length (mm) |  |  | Weight (g) |  |  |

### 3.7 ESA Compliance

The Nason Creek smolt trap was operated under consultation with NMFS and USFWS. Total numbers of UCR spring Chinook and UCR summer steelhead that were captured or handled (indirect take) at the trap were less than the maximum permitted ( $20 \%$ ) for each species. Lethal take was well below the allowable level of $2 \%$ for all ESA-listed species (Table 13). Stream temperatures did not exceed $18^{\circ} \mathrm{C}$ at any time in which fish were being handled.

Table 13. Summary of ESA species and coho salmon mortality at the Nason Creek rotary trap.

| Species/Stage/Brood Year |  |  |  |

### 4.0 DISCUSSION

Operation of the Nason Creek smolt trap in 2016 was, as in 2015, affected by an unseasonably early and warm spring that caused a quickly diminished snowpack. The resulting prolonged base-flow period meant that the trap could not be operated for much ( 70 d ) of the mid to late summer due to insufficient water velocity. Aside from issues associated with the summer low flow period, inactivity due to other environmental conditions and mechanical issues was minimized. The critical assumptions noted in section 2.5.1, upon which the mark-recapture methodology was predicated, were not violated insofar as we could determine from measuring tag retention/tagging mortality, examining the health of all fish in mark groups prior to release, and ensuring that all fish encountered were thoroughly scanned for PIT tags post-release. All prudent measures were taken to ensure that fish used in mark groups avoided predation between point of release and the trap e.g., release into shallow water refugia.

Since establishment in the summer of 2014, smolt trap operations at the Bolser site have occurred largely under a prolonged period of El Niño spanning from approximately October 2014 through June 2016 (NOAA 2016). Oceanic Niño Index (ONI) levels for this period were especially high ( $\geq 2.0$ ), with similar conditions not experienced since warming events in 1982/1983 and 1997/1998. Inland manifestations of this most recent El Niño included variable flow and temperature regimes, often deviating greatly from normal trends in both timing and magnitude (Figure 15). Comparison to the 12-year mean discharge and observed flows shows that high water events occurred early, and in periods in which cold temperature normally limit discharge. Quickly diminished snowpack caused by the high, early winter flows subsequently lead to early spring runoff and prolonged base-flow periods in the summer months.

Figure 15. Nason Creek daily discharge from September 2014 through December 2016, with corresponding 12-year mean Nason Creek discharge.

## Spring Chinook

The 2014 wild spring Chinook brood at Nason Creek yielded the smallest total emigrant estimate on record at the trap. Egg-to-emigrant survival in comparison to the nearby White River and Chiwawa River showed that Nason Creek was the only monitored tributary in the Wenatchee basin to demonstrate a decrease in in-stream survival between the 2013 and 2014 broods despite similar trends in redd deposition (Figure 17). Comparison of egg-to-emigrant survival and estimated egg deposition suggested that between the three tributaries, Nason Creek produced the most marked outlier (Figure 18). The degree to which Nason Creek deviated from the trends seen in the other tributaries may be due to the comparative effect that the El Niño event had on the individual watershed. The smallest, lowest elevation, and warmest of the three tributaries compared, Nason Creek saw the greatest physical impact of the warming phenomenon.

Figure 16. Comparison of wild spring Chinook abundance estimates (BY2007-2014) made at the White River, Nason Creek, and Chiwawa River smolt traps. *Non-trapping estimates not included.

Figure 17. Comparison of egg-to-emigrant survival (BY 2007-2014) and egg deposition for Nason Creek, Chiwawa River, and White River spring Chinook. *Non-trapping estimates not included.

The low comparative survival of BY2014 Chinook was likely due in-apart to decreased survival associated with the anomalous flow and temperature regimes caused by El Niño. Redd scour and sedimentation brought on by irregularly high flows has been shown to increase in-gravel mortality (Montgomery et al. 1996 \& Lotspeich and Everest 1981). Although difficult to quantify the exact influence of scour and sedimentation on our estimates, we assume that the strong negative correlation between juvenile survival and peak flow during incubation demonstrated in other tributaries had some negative influence in Nason Creek (Seiler et al. 2002). Some elevated level of increased mortality was also likely incurred as a result of warm water temperatures, decreased habitat available, and elevated competition for resources during the prolonged base flow period in the summer of 2015. Identified in normal years as an impaired watershed due to regular exceedance of 303(d) criteria, Nason Creek saw three consecutive months in 2015 (June-August) in which maximum temperatures exceeded $22^{\circ} \mathrm{C}$ (Cristea and Pelletier 2005). Marine and Cech (2004) showed that between three laboratory-based rearing temperature regimes ( $13-16^{\circ} \mathrm{C}, 17-20^{\circ} \mathrm{C}$, and $21-24^{\circ} \mathrm{C}$ ), higher water temperatures significantly decreased growth rates, smoltification indices, and predator avoidance capability. Though Marine and Cech did not see any increased mortality associated with higher rearing temperatures, we assume that effects noted in the study would have an impact on survival in-situ.

BY2014 spring Chinook parr that survived the summer months in Nason Creek were then met with extremely high discharges in the month of November 2015. Flows during this high-water event were large enough to cause a major reconfiguration of $\log$ jams and channel morphology in sections. During this period in which we presume a large proportion of the remaining Chinook in Nason Creek were involuntarily pushed out of the system, the trap was unable to run due to water high velocity and debris load. During this event, remote-tagged Chinook were also pushed
from the system when the PIT tag arrays were the least effective. We suspect that along with a higher incidence of in-stream mortality, much of the BY2014 brood left Nason Creek when estimation methodologies were unavailable or ineffective.

A total of only 85 redds in Nason Creek in 2015 was the lowest on record since 2003. The extent to which high winter flows of 2015/2016 affected the BY2015 emigration estimate will potentially be determined upon completion of the outmigration in the summer of 2017. Impact on this brood may be great in that much of the winter flooding occurred pre-emergence; a period of high vulnerability to both scour and sedimentation. The estimated survival of this brood will hopefully indicate the ability of Nason Creek spring Chinook to endure such in-gravel conditions.

## Summer Steelhead

The 2013 Nason summer steelhead brood estimate did not reflect the low survival seen in BY2014 Chinook concluding their outmigration at the same time. Although BY2013 steelhead abundance and survival both fell below their 11-year averages, they were not outliers. This is presumably due to the fact that the overwhelming majority ( $88 \%$ ) of BY2013 steelhead emigrants left during the spring of 2014; a period not characterized by irregularly high flows or preceded by adverse rearing conditions. The BY2013 age-2 and age-3 emigrant estimates are based on pooled efficiencies, and will be recalculated upon establishment of a viable multi-year regression. Recalculation of these estimates based on a flow-efficiency regression will most likely result in a slightly lower total estimate due to the pooled estimates use of low fixed efficiencies ( $0.86 \%$ and $1.34 \%$ ). However, because age-2 \& 3 steelhead emigrants comprise a relatively small proportion of the total outmigration, recalculation may not change in-stream survival to a great extent.

Potential effects of the El Niño period on developing (BY2014 and BY2015) estimates are still unclear due to the use of pooled estimates employing the aforementioned low fixed efficiencies. BY2014 and BY2015 estimates thus far have produced age-1 estimates that are markedly higher than the 11-year mean. Completion of both emigrant estimates as well as recalculation with a viable flow-efficiency regression will determine if this high abundance is accurate, and in stark contrast to the poor survival calculated in cohabitating spring Chinook.

## Coho

Despite a relatively large Wenatchee basin spawner escapement in 2014, only 16 redds were documented in Nason Creek; below the 11-year mean of 24 redds. The resulting total emigrant estimate was also below the 11-year mean, and in the absence of a flow-efficiency regression, calculated with a pooled estimate. As with similar methodologies used to calculate other species abundances in the absence of a flow-efficiency relationship, we suspect that these pooled estimated are likely overestimated due to low efficiencies used. BY2014 coho were likely affected by the El Niño weather trend similarly to BY2014 spring Chinook, given similar instream residence times.

A poor adult coho return in 2015 required exhaustive broodstock retention at Tumwater dam to meet hatchery production goals. As a result, no coho were documented in Nason Creek. This is reflected in the complete lack of BY2015 subyearlings at the trap during the 2016 trap year. Given little coho passage above Tumwater dam, and a very small likelihood that any spawning activity occurred in Nason Creek in 2015, we suspect that yearling emigrants will be absent completely for this brood as well.

## Appendix M

Fish Trapping at the White River Smolt Trap during 2016

# Population Estimates for Juvenile Spring Chinook Salmon in White River, WA 

## 2016 Annual Report

Prepared by:
Bryan Ishida

YAKAMA NATION
FISHERIES RESOURCE MANAGEMENT
Toppenish, WA 98948

Prepared for:
Public Utility District No. 2 of Grant County
Ephrata, Washington 98823

#### Abstract

In 2007, Yakama Nation Fisheries Resource Management began monitoring emigration of Endangered Species Act (ESA) listed Upper Columbia River (UCR) spring Chinook salmon in the White River to provide abundance and freshwater survival estimates. This report summarizes data collected between March 1 and November 30, 2016. We used a 1.5 m rotary screw trap to collect 200 juvenile spring Chinook; 50 fry, 147 subyearling parr, and 3 yearling smolts. Daily counts at the trap were expanded via regression analysis derived from mark and recapture trials. We estimated that 386 ( $\pm 701$; 95\% CI) BY2014 wild spring Chinook smolts and 2,430 ( $\pm 723$; 95\% CI) BY2015 wild spring Chinook parr emigrated past the White River trap in 2016. Combined with data collected in 2015, this gives us a total estimate of 2,336 ( $\pm 807 ; 95 \%$ CI) BY2014 emigrants. Using spring Chinook spawning ground data collected by Washington Department of Fish and Wildlife (WDFW) in 2014, we estimated egg-to-emigrant survival of BY2014 spring Chinook to be $2.2 \%$ ( 90 smolts-per-redd).

## ACKNOWLEDGEMENTS

This project is part of a basin-wide monitoring program requiring close coordination between multiple agencies and contractors. We greatly appreciate the hard work of the Yakama Nation FRM crew members including Matthew Clubb, Jamie Hallman, Tim Jeffris and Kevin Swager who maintained and operated the trap during all hours including nights/weekends and inclement weather conditions. Also thank you to Peter Graf (Grant County PUD) for administering contracting and funding as well as Mike Hughes, Mclain Johnson, Andrew Murdoch, and Josh Williams (WDFW) for data sharing and collaboration on smolt trap methodologies.

### 1.0 INTRODUCTION

White River spring Chinook salmon (tkwínat) Oncorhynchus tshawytscha are part of the Upper Columbia River (UCR) spring Chinook salmon Evolutionarily Significant Unit (ESU), which was listed as endangered under the Endangered Species Act (ESA) in 1999. Due to critically low abundance, a captive broodstock program was operated in the White River between 1997 and 2015 as a risk aversion measure. Determining freshwater productivity of spring Chinook salmon in the White River is an essential component to overall population monitoring, and will help contribute to the body of knowledge needed to evaluate if further supplementation in the White River is warranted.

In the fall of 2005, Washington State Department of Fish and Wildlife (WDFW) began smolt trapping in the lower White River in order to provide an estimate of juvenile spring Chinook salmon production. No trapping was conducted in 2006 as there was a transition between trap operators. In 2007, Public Utility District No. 2 of Grant County (GCPUD) contracted with Yakama Nation Fisheries (YNF) to operate a rotary trap in the White River. This document reports data collected between March 1 and November 30, 2016, and provides emigration estimates for spring Chinook salmon yearlings (BY2014) and subyearlings (BY2015) during that time period. Fish trap operations were conducted in compliance with ESA consultation specifically to address abundance and productivity of spring Chinook salmon in the White River.

Within this document, we will report:

1) Juvenile abundance and productivity of spring Chinook salmon in the White River.
2) Emigration timing of spring Chinook salmon emigrating from the White River.

### 1.1 Watershed Description

The White River drainage encompasses 40,451 ha originating in alpine glaciers and perennial snow fields (Figure 1; USFS 2004). Elevation within the drainage varies from 569 m at the surface of Lake Wenatchee to $2,614 \mathrm{~m}$ at Clark Mountain (Andonaegui 2001). As one of two primary tributaries to Lake Wenatchee, the White River flows in a south-easterly direction for 42.9 rkm before emptying into the lake. Precipitation ranges from 79 cm at the mouth to more than 356 cm in the head waters (Andonaegui 2001). Due to its glacial origins, peak runoff for the White River typically occurs between April and July with occasional high

Figure 1. Map of the Wenatchee River subbasin with White River rotary trap location.
flows caused by rain-on-snow events in the fall and winter months. Water temperatures in this watershed tend to be cooler than other tributaries to the upper Wenatchee River subbasin. As of September 2002, Washington State Department of Ecology (WDOE) began operating a stream monitoring station at rkm 9.9 . Operation of this station by WDOE is currently maintained with funding provided by GCPUD. In 2016, daily mean stream discharge ranged from $2.5 \mathrm{~m}^{3} / \mathrm{s}(87$ cfs) to $120 \mathrm{~m}^{3} / \mathrm{s}(4,420 \mathrm{cfs})$ while mean daily stream temperatures ranged from $0.0^{\circ} \mathrm{C}$ to $14.6^{\circ} \mathrm{C}$ (Figs. 2 \& 3). Discharge and temperature data provided by WDOE should be considered provisional and are presented in Appendix A.

Figure 2. Mean daily stream discharge at the White River DOE stream monitoring station at Sears Creek Bridge, 2016.

Figure 3. Mean daily water temperatures at the White River DOE stream monitoring station at Sears Creek Bridge, 2016.

The White River drainage has had minimal riparian harvest from the 1950's to the present on federally owned land. Turn of the century settlement and land clearing have impacted the
riparian reserve network up to the Napeequa confluence, yet, riparian areas in the mainstem below Panther Creek remain in fair condition (USFS 2004). In the remainder of the watershed, woody debris recruitment, shade, aquatic habitat connectivity, and riparian vegetation appear to be in good condition. Current habitat concerns pertaining to the development of homes and vacation retreats on private lands do exist. Rip-rapping, channel constriction, and stream degradation are considered minor in the watershed. Public ownership comprises $78 \%$ of the drainage area; more than half of public land is located within the Glacier Peak Wilderness. The remaining $22 \%$ of the drainage is in private ownership (USFS 2004).

Downstream of White River Falls are key spawning grounds for spring Chinook salmon (tkwínat) Oncorhynchus tshawytscha, sockeye salmon (kálux) O. nerka, and bull trout Salvelinus confluentus. Two large tributaries to the White River, Napeequa River and Panther Creek, are also known to support populations of anadromous salmonids (Mullen et al. 1992). For a complete list of known fish species encountered in the White River see (3.4 Incidental Species).

### 2.0 METHODS

### 2.1 Trapping Equipment and Operation

In 2016, a 1.5 m diameter cone rotary trap was operated in a single position at all discharge levels. This revised trapping regime was implemented in 2013 to simplify data analysis by eliminating obsolete trap positions that generated very little data. Past attempts at developing a high flow position generated very few efficiency trials resulting in limited trap efficiency data. Operating season-long at a single position, the trap was suspended from a river-spanning cable from which its position could be adjusted perpendicular to stream flow by hand powered winches anchored on a tree on the river-right bank.

The trap was operated 24 hours per day, seven days per week for the majority of the season. During spring snowmelt, operations only occurred during hours of darkness to minimize trap damage and subsequent capture mortality; still enabling sampling during the hours of peak fish movement. When trap operations were suspended, the cone was raised to avoid damage by debris.

During all ranges of river discharge, fish were removed daily. Additional trap checks were necessary during periods of high discharge in the spring, and in the autumn due to increased leaf litter. Debris in the live-box was removed continually by a rotating drum screen located at the rear of the holding box and hydraulically powered by the cone. A record of daily trap operations is provided in Appendix B.

### 2.2 Biological Sampling

Trap operating procedures and techniques followed a standardized, basin-wide monitoring plan developed by the Upper Columbia Regional Technical Team (UCRTT) for the Upper Columbia Salmon Recovery Board (UCSRB; Hillman 2004), which was adapted from Murdoch \& Petersen (2000).

Captured fish were transferred from the rotary trap's live box using covered five-gallon plastic buckets to a stream-side portable sampling station. Fish were anesthetized in a solution of tricaine methanesulfonate (MS-222) to facilitate sampling and reduce handling stress. Fork length (FL) and weight were recorded for all fish, except large numbers of sockeye fry. For these fish, a daily subsample of 25 individuals was measured while the remaining fish were enumerated and released. Weight was measured to the nearest 0.1 g with a portable digital scale while FL was recorded to the nearest 1.0 mm using a trough-type measuring board. These data were used to calculate a Fulton-type condition factor (K-factor) for each target species using the formula:

$$
K=\left(W / L^{3}\right) \times 100,000
$$

where $K=$ Fulton-type condition metric;
$W=$ weight in grams;
$L=$ fork length in millimeters;
And 100,000 is a scaling constant.
Portable aerators were used to oxygenate holding water during sampling. All fish were allowed to fully recover from anesthesia before being released. Spring Chinook salmon were classified as either natural or hatchery origin by the presence/absence of coded wire tags (CWT's). Developmental stages (fry, parr, transitional or smolt) were visually identified and assigned to each individual sampled. Transitional juveniles were identified as having both parr and smolt characteristics; visible parr marks, semi-transparent fin coloration along with silvery coloration throughout body. Smolts were identified by a strong silvery coloration over entire body and faint or absent parr marks. Fry were defined as newly emerged fish with or without a visible yolk sac and a FL measuring < 50 mm . Age-0 spring Chinook salmon captured before July 1 were considered 'fry' and excluded from population estimates due to the inconclusive nature of their movement (i.e. active emigration or local distribution in-stream). Age-0 spring Chinook salmon captured after 1 July were considered subyearling emigrants and included in the population estimate (UCRTT, 2001).

Tissue samples (caudal clip) were taken from spring Chinook salmon and applied to blotter sheets. Samples were provided to WDFW for reproductive success analysis. Scale samples were also collected from all steelhead captured. Scale samples were submitted to WDFW for age analysis. Bull trout tissue or scale samples were not collected in 2016.

During periods when the trap operations were suspended (e.g. - high discharge, high debris and/or mechanical problems), passage estimates were generated to account for emigrants during these time periods. This estimate was calculated using the average number of fish captured three days prior and three days after the break in operation (Hillman et al., 2013; Snow et al., 2013).

### 2.3 Mark-Recapture Trials

Groups of marked spring Chinook salmon were used for trap efficiency trials. Fish were marked by insertion of a passive integrated transponder (PIT) tag into the abdominal cavity. Ideally, marked groups of fish would be released over a broad range of stream discharges in order to determine a trap efficiency-discharge relationship. (See 2.4 Data Analysis). However, due to low abundance and limited holding time of ESA-listed species (reducing the ability to meet trials size requirements on a more consistent basis), marked groups were released whenever the minimum sample size ( $\geq 20$ ) was obtained. Mark-recapture (M-R) trials followed the protocol described in Hillman (2004). Although the protocol suggests a minimum sample size of 100 fish for each mark-group, the limited abundance of juvenile emigrants from the White River required that efficiency trials be completed with much smaller sample sizes. YN's continued goal is to increase individual mark-group sizes, when possible, to meet the standard described above.

Number of wild fish included in a marked group was maximized by combining catches from three days of trapping. Fish were held up to 72 hours prior to release in holding boxes located on the river-left bank. Fish to be used in efficiency trials were then transported in five gallon buckets $\sim 1.0 \mathrm{rkm}$ upstream to the release location at Sears Creek Bridge (rkm 10.3). All mark groups are released by hand at nautical twilight.

Each M-R trial was conducted over a three-day (72 hour) period to allow time for passage or capture. Completed trials were only considered invalid if an interruption to trapping occurred or proper pre-release procedures were not followed. Trials resulting in zero recaptures were included in the efficiency regression as allowed by the new method of observed trap efficiency calculation (See equation 3 in 2.5.1 Estimate of Abundance).

### 2.3.1 Marking and PIT tagging

All spring Chinook and summer steelhead juveniles with FL $\geq 60 \mathrm{~mm}$ were PIT tagged unless the health of a specimen was in question. Once anesthetized, each fish was examined for external wounds or descaling and scanned for the presence of a previously implanted PIT tag. If a tag was not detected, a pre-loaded 12mm Digital Angel 134.2 kHz type TX 1411ST PIT tag was inserted into the body cavity using a Biomark MK-25 Rapid Implant Gun. Each unique tag code was electronically recorded with an appropriate tagging date, release date, tagging personnel and biological data. These data were entered into $\mathrm{P}_{3}$ and submitted to the PIT Tag Information System (PTAGIS) at the end of each month. Tagging methods were consistent with methodology described in the PIT Tag Marking Procedures Manual (CBFWA 1999) as well as with 2008 ISEMP protocols (Tussing 2008).

After marking and/or PIT tagging, fish were held for a minimum of 24-hours to a) ensure complete recovery, b) assess tagging mortality and c) determine tag-shed rate. Fish that were not to be used in an efficiency trial were released downstream of the smolt trap.

### 2.4 Data Analysis

### 2.4.1 Estimate of Abundance

Seasonal juvenile migration, N , was estimated as the sum of daily migrations, $N_{i}$, i.e., $N=\sum_{i} N_{i}$, and daily migration was calculated from catch and efficiency:

$$
\begin{equation*}
\hat{N}_{i}=\frac{C_{i}}{\hat{e}_{i}} \tag{1}
\end{equation*}
$$

where $C_{i}=$ number of fish caught in period $I$;
$\hat{e}_{i}=$ trap efficiency estimated from the flow-efficiency relationship, $\sin ^{2}\left(b_{0}+b_{1}\right.$ flow $\left.w_{i}\right)$,
where $b_{0}$ is estimated intercept and $b_{1}$ is the estimated slope of the regression.

The regression parameters $b_{0}$ and $b_{1}$ are estimated using linear regression for the model:

$$
\begin{equation*}
\arcsin \left(\sqrt{e_{k}^{\text {obs }}}\right)=\beta_{0}+\beta_{1} \text { flow }_{k}+\varepsilon \tag{2}
\end{equation*}
$$

where $e_{k}^{\text {obs }}=$ observed trap efficiency of Eq. 2 for trapping period $k$;
$\beta_{0}=$ intercept of the regression model;
$\beta_{1}=$ slope parameter;
$\mathcal{E}=$ error with mean 0 and variance $\sigma^{2}$.
In Equation 2, the observed trap efficiency, $e_{k}^{o b s}$, is calculated as follows,

$$
\begin{equation*}
e_{k}^{o b s}=\frac{r_{k}+1}{m} \tag{3}
\end{equation*}
$$

The estimated variance of seasonal migration is calculated from daily estimates as:

$$
\operatorname{Var}\left(\sum_{i=1}^{n} \hat{N}_{i}\right)=\underbrace{\sum_{i} \operatorname{Var}\left(N_{i}\right)}_{\text {Part A }}+\underbrace{\sum_{i} \sum_{j} \operatorname{Cov}\left(N_{i}, N_{j}\right)}_{\text {Part B }},
$$

or,

$$
\begin{equation*}
\operatorname{Var}\left(\sum_{i=1}^{n} \hat{N}_{i}\right)=\underbrace{\sum_{i} \operatorname{Var}\left(\frac{\left(C_{i}+1\right)}{\hat{e}_{i}}\right)}_{\text {Part A }}+\underbrace{\sum_{i} \sum_{j} \operatorname{Cov}\left(\frac{\left(C_{i}+1\right)}{\hat{e}_{i}}, \frac{\left(C_{j}+1\right)}{\hat{e}_{j}}\right)}_{\text {Part B }} . \tag{4}
\end{equation*}
$$

Part A of equation 4 is the variance of daily estimates. Part B is the between-day covariance. Note that the between-day covariance exists only for days that use the same trap efficiency model. If, for example, day 1 is estimated with one trap efficiency model, and day 2 estimated from a different model, then there is no covariance between day 1 and day 2 . The full expression for the estimated variance:

$$
\begin{aligned}
\operatorname{Var}\left(\sum_{i=1}^{n} \hat{N}_{i}\right)= & \underbrace{\sum_{i} \hat{N}_{i}^{2}\left(\frac{N_{i} \hat{e}_{i}\left(1-\hat{e}_{i}\right)}{\left(C_{i}+1\right)^{2}}+\frac{4\left(1-\hat{e}_{i}\right)}{\hat{e}_{i}} \operatorname{Var}\left(b_{0}+b_{1} \text { flow }_{i}\right)\right)}_{\text {PartA }}+ \\
& \underbrace{\sum_{i} \sum_{j} 4\left(\hat{N}_{i}\left(1-\hat{e}_{i}\right)\right)\left(\hat{N}_{j}\left(1-\hat{e}_{j}\right)\right) \cdot\left[\hat{\operatorname{Var}}\left(b_{0}\right)+\text { flow }_{i} \text { flow }_{j} \hat{\operatorname{Var}}\left(b_{1}\right)\right]}_{\text {PartB }}
\end{aligned}
$$

where $\operatorname{Var}\left(b_{0}+b_{1}\right.$ flow $\left._{i}\right)=\operatorname{M\hat {S}E}\left(1+\frac{1}{n}+\frac{\left(\text { flow }_{i}-\overline{\text { flow }}\right)^{2}}{(n-1) s_{\text {flow }}^{2}}\right)$, and $\hat{\operatorname{Var}}\left(b_{0}\right)$ and $\hat{\operatorname{Var}}\left(b_{1}\right)$ are
obtained from regression results. In Excel, the standard error (SE) of the coefficients is provided. The variance is calculated as the square of the standard error, $S E^{2}$.

In cases when there was no significant flow-efficiency relationship (i.e., low correlation), then a pooled, or average trap efficiency will suffice for the stratum. The estimator is calculated as follows:

$$
\hat{\bar{e}}=\frac{\sum_{j=1}^{k} r_{j}}{\sum_{j=1}^{k} m_{j}}
$$

where $\hat{\bar{e}}=$ the average or pooled trap efficiency for the stratum;
$m_{j}=$ the number of smolts marked and released in efficiency trial $j$ for the stratum;
$r_{j}=$ the number of smolts recaptured out of $m_{j}$ marked fish in efficiency trial $j$.

Abundance for a trapping period is estimated as:

$$
\hat{N}_{i}^{\text {pooled }}=\frac{C_{i}}{\hat{\bar{e}}},
$$

,and total stratum abundance is:

$$
N^{\text {pooled }}=\sum_{i} \hat{N}_{i}^{\text {pooled }} .
$$

The variance of seasonal abundance takes into account the variability in catch numbers that are a result of binomial sampling (Part A), the pooled variance of trap efficiency, $\hat{\bar{e}}$ (Part B), and the covariance in daily estimates that arises from using a common estimate of efficiency across all trapping days (Part C):

$$
\operatorname{Var}\left(\sum_{i=1}^{n} \hat{N}_{i}^{\text {pooled }}\right)=\underbrace{\left(\sum_{i} \frac{\hat{N}_{i}(1-\hat{\bar{e}})}{\hat{\bar{e}}}\right)}_{\text {PartA }}+\underbrace{\frac{\operatorname{Var}(\hat{\bar{e}})}{\hat{\bar{e}}^{2}} \sum_{i} \hat{N}_{i}^{2}}_{\text {PartB }}+\underbrace{\frac{\operatorname{Var}(\hat{\bar{e}})}{\hat{\bar{e}}^{2}} \sum_{i} \sum_{j} \hat{N}_{i} \hat{N}_{j}}_{\text {PartC }} .
$$

The Part B and Part C terms are combined in the calculation as a new Part B:

$$
\operatorname{Var}\left(\sum_{i=1}^{n} \hat{N}_{i}^{\text {pooled }}\right)=\underbrace{\left(\sum_{i} \frac{\hat{N}_{i}(1-\hat{\bar{e}})}{\hat{\bar{e}}}\right)}_{\text {PartA }}+\underbrace{\frac{\operatorname{Var}(\hat{\bar{e}})}{\hat{\bar{e}}^{2}}\left[\sum_{i} \hat{N}_{i}^{2}+\sum_{i} \sum_{j} \hat{N}_{i} \hat{N}_{j}\right]}_{\text {PartB }} .
$$

The variance of $\hat{\bar{e}}$ is calculated as:

$$
\operatorname{Var}(\hat{\bar{e}})=\operatorname{Var}\left(\frac{\sum_{k=1}^{n} r_{k}}{\sum_{k=1}^{n} m_{k}}\right)=\frac{\sum_{k=1}^{n}\left(r_{k}-\hat{\bar{e}}_{k} m_{k}\right)^{2}}{\bar{m}^{2} n(n-1)}
$$

where $\bar{m}$ is the average release size across all efficiency trial, $\frac{\sum_{k=1}^{n} m_{k}}{n}$.
Confidence intervals were calculated using the following formulas:

$$
95 \% \text { confidence interval }=1.96 \times \sqrt{\sum \operatorname{var}}\left[\hat{N}_{i}\right]
$$

The single M-R estimator of abundance carries a set of well documented assumptions (Everhart and Youngs 1981; Seber 1982),

1. The population is closed to mortality.
2. The probability of capturing a marked or unmarked fish is equal.
3. Marked fish were randomly dispersed in the population prior to recapture.
4. Marking does not affect probabilities of capture.
5. Marks were not lost between the time of release and recapture.
6. All marks are reported upon recapture.
7. The number of fish in the trap, C , is fully enumerated and known without error.

### 3.0 RESULTS

### 3.1 Dates of Operation

In 2016, YNF operated a 1.5 m rotary trap between March 1 and November 30. During this period, the trap operated 24 hours per day, 7 days per week barring inoperable environmental conditions (i.e. heavy debris loads or high discharge). Trapping was interrupted a total of 29 days (Table 1).

Table 1. Summary of White River smolt trap operation, 2016.

| Trap <br> Status | Description | Days |
| :--- | :--- | :---: |
| Operating | Continuous data collection | 246 |
| Interrupted | Unexpected interruption by debris, etc. | 29 |
| Pulled | Intentionally pulled to protect the trap during high flows | 0 |

### 3.2 Daily Captures and Biological Sampling

### 3.2.1 Wild Spring Chinook Yearlings (BY2014)

Three wild yearling Chinook smolts were collected between March 1 and June 30 (Figure 4). Mean fork-length (FL) was $106 \mathrm{~mm}(n=3 ; S D=1.5)$ and mean weight was $12.4 \mathrm{~g}(n=3 ; S D=$ 0.3; Table 2). All spring Chinook smolts were implanted with PIT tags and sampled for genetics. There were no BY2014 spring Chinook mortalities incurred (See 3.4 ESA Compliance).

Figure 4. Daily catch of yearling spring Chinook smolt with mean daily stream discharge at the White River rotary trap, March 1 to June 30, 2016.

### 3.2.2 Wild Spring Chinook Subyearlings (BY2015)

Spring Chinook fry were captured at the trap between March 7 and June $22(n=49)$. During this period there were no fry trapping mortalities incurred. One additional subyearling Chinook with FL<50 mm was captured after June 30. Because this fish is considered a "fry" it was excluded from the parr estimate. A total of 147 wild subyearling Chinook parr were collected between May 25 and November 30, with peak catch occurring on August 25 ( $n=14$; Figure 5). The mean FL for subyearling parr was $89 \mathrm{~mm}(n=147 ; S D=10.7)$ and the mean weight was $8.3 \mathrm{~g}(n$ $=147 ; S D=2.8$ ); see Table 2. Four of the spring Chinook parr were captured prior to July 1 . Because these were therefore considered "fry" they were excluded from the parr estimate. PIT tags were implanted into a total of 137 subyearling Chinook parr. One tag was shed during the 24 hr holding period (Table 4). Genetic samples were taken from 137 parr. There were two BY2015 spring Chinook mortalities during the 2016 trapping season (See 3.4 ESA Compliance).

Figure 5. Daily catch of wild subyearling spring Chinook with mean daily stream discharge at the White River rotary trap, July 1 to November 30, 2016.

Table 2. Summary of length and weight sampling of juvenile spring Chinook captured at the White River rotary trap, 2016.

| Brood <br> Year | Origin/Species/Stage | Fork Length (mm) |  |  | Weight (g) |  |  | K- <br> factor |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Mean | n | SD | Mean | n | SD |  |
| 2014 | Wild Yearling Smolt | 106 | 3 | 1.5 | 12.4 | 3 | 0.3 | 1.05 |
| 2015 | Wild Subyearling Fry | 38 | 50 | 3.0 | 0.5 | 49 | 0.3 | 0.82 |
| 2015 | Wild Subyearling Parr | 89 | 147 | 10.7 | 8.3 | 147 | 2.8 | 1.13 |

### 3.3 Trap Efficiency Calibration and Population Estimates

### 3.3.1 Wild Spring Chinook Yearlings (BY 2014)

Due to low abundance, no BY2014 wild yearling Chinook efficiency trials were performed in 2016. A composite regression model using previous year's (2008-2012) efficiency trials showed statistically significant $\left(r^{2}=0.57 ; p=0.001\right)$ flow-efficiency relationship, and was used to calculate yearling abundance. Use of a single spring trapping position allowed this regression to be applied to all yearling Chinook captured in 2016. Weighting of this regression via an R script (provided by WDFW) did not affect calculation parameters greatly and yielded the same r-square and $p$-values. In the fall of 2015, we estimated that $1,950( \pm 400 ; 95 \% \mathrm{CI}) \mathrm{BY} 2014$ subyearlings emigrated past the trap. In the spring of 2016, we estimated that $386( \pm 701 ; 95 \%$ CI) emigrated past the trap. Combining the two estimates, total BY2014 wild spring Chinook emigrants was 2,336 ( $\pm 807$; 95\% CI; Table 3).

### 3.3.2 Wild Spring Chinook Subyearling (BY 2015)

Due to low abundance, no BY2015 wild yearling Chinook efficiency trials were performed in 2016. Instead, a composite regression based on previous year's data (2009-2015) was used to expand daily catch. This regression was comprised of all trails conducted fulfilling the minimum number marked ( $n \geq 20$ ) including efforts in which zero recaptured were made (Appendix C). Mark-groups in which validity of the trial could be called into question (suspected trap stoppage or improper pre-release handling of the mark group) were removed. The weighted regression was not significant $\left(r^{2}=0.12 ; p=0.086\right)$ at our accepted limit $(\alpha=0.05)$. However, after comparison with a pooled method and considerations of the pooled estimate limitations, we decided to use the regression model despite its slightly higher $p$-value. This single regression was the only model required to estimate total subyearling migration due to the fact only one fall trapping position was used in 2015. We estimated that in 2016, 2,430 ( $\pm 723 ; 95 \%$ CI) spring Chinook subyearling parr moved past the trap (Table 3).

Table 3. Estimated egg-to-emigrant survival and emigrants per redd for White River spring Chinook

| Brood <br> Year | No. of Redds ${ }^{\text {a }}$ | Fecundity ${ }^{\text {b }}$ | No. of Eggs | No. of Emigrants |  |  | Egg-to Emigrant | Emigrants per Redd |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  | Age-0 ${ }^{\text {c }}$ | Age-1 | $\begin{gathered} \text { Total } \pm 95 \% \\ \text { CI } \\ \hline \end{gathered}$ |  |  |

Estmated Egg Deposition

Figure 6. Relationships between estimated egg deposition and total emigrants produced, egg-to-emigrant survival, and emigrants per redd for White River spring Chinook, BY 2007 to 2014. *BY2014 values denoted by red border.

### 3.4 PIT Tagging

In 2016, a total of 140 spring Chinook and 5 steelhead were PIT tagged at the trap. PIT tag retention after 24 hours of observation yielded only one shed tag (wild spring Chinook parr; Table 4). There no tagging mortalities (Table 6).

Table 4. Number of PIT tagged spring Chinook and steelhead with shed rates at the White River rotary trap, 2016.

| Brood <br> Year | Species/Stage | Total <br> Catch | Total PIT <br> Tagged | Percent <br> Tagged | Percent Tags <br> Shed |
| :---: | :--- | :---: | :---: | :---: | :---: |
| 2014 | Yearling Chinook Smolt | 3 | 3 | $100.0 \%$ | $0.0 \%$ |
| 2015 | Subyearling Chinook Parr | 147 | 137 | $93.2 \%$ | $0.7 \%$ |
| $*$ | Steelhead Parr | 5 | 5 | $100.0 \%$ | $0.0 \%$ |

* Brood year unknown

### 3.5 Incidental Species

Incidental species were enumerated and sampled for length and weight (Table 5). Incidental species included: bull trout, longnose dace Rhinichthys cataractae, mountain whitefish Prosopium williamsoni, northern pikeminnow Ptychocheilus oregonensis, steelhead/rainbow trout (shúshaynsh) Oncorhynchus mykiss, redside shiner Richardsonius balteatus, sculpin Cottus sp., sockeye salmon, sucker Catostomus sp., and westslope cutthroat Oncorhynchus clarkii lewisi.

Table 5. Summary of length and weight sampling of incidental species captured at the White River rotary trap, 2016.

| Species | Total Count | Fork Length (mm) |  |  | Weight (g) |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Mean | $n$ | SD | Mean | $n$ | SD |
| Bull Trout Parr | 5 | 341 | 5 | 220.5 | 98.9 | 3 | 89.5 |
| Longnose Dace | 4 | 73 | 4 | 24.5 | 5.9 | 4 | 4.7 |
| Mountain Whitefish | 93 | 64 | 93 | 29.7 | 6.2 | 83 | 19.6 |
| Northern Pikeminnow | 5 | 211 | 5 | 142.8 | 51.7 | 4 | 77.6 |
| Rainbow Trout/Steelhead Parr | 5 | 10 | 5 | 23.1 | 5.6 | 0 | 158.8 |
| Redside Shiner | 25 | 67 | 25 | 13.8 | 5.5 | 25 | 5.0 |
| Sculpin | 60 | 61 | 60 | 16.5 | 3.1 | 57 | 2.4 |
| Sockeye Fry | 1,784 | 27 | 864 | 1.1 | - | - | - |
| Sockeye Parr | 1 | 68 | 1 | - | 3.1 | 1 | - |
| Sucker | 20 | 213 | 20 | 76.9 | 159.0 | 20 | 109.3 |
| Westslope Cutthroat | 6 | 229 | 6 | 75.2 | 90.3 | 5 | 46.8 |

### 3.6 ESA Compliance

ESA-listed species mortalities incurred in 2016 included two subyearling Chinook parr (Table 6). At no point during the trapping season did the lethal take of wild spring Chinook exceed the maximum allowed $2 \%$. All fish handled were inspected prior to tagging or further sampling with any sign of injury or stress warranting immediate release.

Table 6. Summary of White River ESA listed species catch and mortality, 2016.

| Species/Stage | Total Catch | Total Mortality | Total \% <br> Mortality |
| :--- | :---: | :---: | :---: | :---: |
| Yearling Chinook Smolt | 3 | 0 | $0.0 \%$ |
| Subyearling Chinook Parr | 147 | 2 | $1.4 \%$ |
| Subyearling Chinook Fry | 50 | 0 | $0.0 \%$ |
| Total Wild Spring Chinook | $\mathbf{2 0 0}$ | $\mathbf{2}$ | $\mathbf{1 . 0 \%}$ |
| Bull Trout | 5 | 0 | $0.0 \%$ |
| Steelhead/Rainbow Trout | 5 | 0 | $0.0 \%$ |

### 4.0 DISCUSSION

Previously, below-average spring Chinook spawner escapements at the White River have resulted in elevated egg-to-emigrant survival estimates for their respective juveniles produced. Conversely, above-average spawner escapements have trended toward comparatively lowered rates of in-stream survival. Although replication at the highest escapement levels is limited, the trend thus far suggests that density-dependent constraints are influencing in-stream survival in the White River spring Chinook population. An estimated egg deposition in 2014 that fell wellbelow the White River average failed to produce the expected response of an elevated egg-toemigrant survival. Instead, the BY2014 egg-to-emigrant survival rate of $2.2 \%$ showed no change over the two preceding broods, which had markedly higher estimated egg depositions. Potential explanations of this unexpected result are twofold: 1) the survival estimated is in fact a reflection of decreased survival, and contrary to the density-dependent trend previously noted, and/or 2) catch at the trap during the BY2014 migration did not effectively capture a representative sample of the outmigration. The likelihoods of both of these influences were exacerbated by the strong El Niño occurring during the majority of BY2014's in-stream rearing period (NOAA 2016).

Oceanic Niño Index (ONI) values were particularly high in 2015 and 2016, with levels not experienced since strong El Niño events in 1982/1983 and 1997/1998 (NOAA 2016). Inland manifestations of this oceanic phenomenon at the White River included high fall and winter discharges (Figure 7). High, irregular flows were likely to have produced some degree of increased mortality prior to gravel emergence as a result of redd scouring and sedimentation (Montgomery et al. 1996 \& Lotspeich and Everest 1981). Flood events in November 2014 and 2015 were both great ( $>170 \mathrm{~m}^{3} / \mathrm{s}$ [6,000cfs]), and included significant movement of bedload, suspended sediments, and large woody debris (LWD). Though difficult to quantify the impact of this flooding on incubating eggs, a strong negative correlation between egg-to-emigrant survival and peak flow during incubation has been shown in other tributaries (Seiler et al. 2002). Also, low snowpack and early snowmelt brought on by mild winter temperatures caused prolonged periods of summer base flows in 2015 and 2016. Though stream temperatures did not reach levels in which mass die-off was incurred ( $\mathrm{Max}=17.6^{\circ} \mathrm{C}$ ), prolonged low stream levels presumably resulted in a higher than average competition for critical resources.

Figure 7. White River daily mean and 13-year mean discharge during strong El Niño, 2014-2016.

In addition to direct decreases to survival, we suspect that irregular weather patterns attributed to El Niño resulted in a potentially large portion of the BY2014 juvenile population being prematurely displaced during periods of low trap efficiency (high discharge), and/or early outmigration during the non-trapping period (December through February). While some displacement below the trap may be a simple function of pre-migratory fish being unable to maintain positioning during high-water events, Chinook populations elsewhere have displayed early migratory behavior in years with early snowmelt and warm water temperatures (Quinn 2005 \& Achord et al. 2007). Early outmigration has also been associated with elevated growth, with larger fish tending to emigrate earlier (Achord et al. 2007). BY2014 subyearling parr had the highest average FL of any brood recorded. Given fulfillment of both conditions (warm water temperature and rapid-growth), BY2014 yearlings may have actively emigrated from the White River earlier than in previous years with typical temperature and flow regimes. If the bulk of movement was initiated prior to the start of trapping (March 1), spring operations may have captured a smaller than average proportion of the total outmigration i.e., only the tail-end of the downstream movement.

A comparison of egg-to-emigrant survival rates in the White River, Chiwawa River, and Nason Creek shows that BY2014 survivals deviated markedly from each other in comparison to the preceding two broods (Figure 8). We suspect that this may be explained in-part by differing felt effects of El Niño on each tributary, and capability of each trap to measure outmigration in light of high flows and early migratory behavior. Stronger influence of El Niño on a tributary would therefore cause a lowered estimated survival rate via the aforementioned effects on both survival and smolt trap efficacy. All three tributaries saw smaller spawner escapements in 2014. Based on previous data, all should have in-turn responded with elevated rates of egg-to-emigrant survival. We suspect that although the Chiwawa River did experience some adverse
environmental effects, influence of El Niño on the Chiwawa BY2014 emigrant estimate was the least affected of the three tributaries. Nason Creek showed potentially the greatest negative response to El Niño, with a decrease in survival. The smallest of the three tributaries, Nason Creek is listed as impaired due to water temperatures exceeding 303(d) criteria (Cristea and Pelletier 2005). Survival in Nason Creek may have been impacted by the prolonged, extremely warm temperatures to a higher degree than the Whiter River and Chiwawa River; two tributaries with much cooler summer water temperatures. Like Nason Creek, the White River failed to show an increase in survival in-light of a smaller adult return. However, given the assumption that a potentially significant proportion of the run was missed producing an underestimate of abundance, we assume that BY2014 survival did in fact increase over the previous brood, as did the Chiwawa River population.

Figure 8. Comparison of wild spring Chinook abundance estimates (BY2007-2014) made at the White R., Nason Cr., and Chiwawa R. smolt traps. Chiwawa R. data provided by Hillman et al. (2015).

The 2015 White River spring Chinook brood in-stream rearing period also coincided partially with the El Niño event. The initial subyearling estimate is below the nine-year mean despite high estimated egg deposition; potentially the result of decreased survival and/or shifts in movement to low-efficiency or suspended periods of trapping. Completion of the migratory period in the spring of 2017 will help to determine the cumulative effect of the anomalous weather trends on the brood estimate. Given a change to cooler conditions associated with nonEl Niño periods, we anticipate that the majority of BY2015 smolt emigration will occur after the smolt trap has been installed.

#### Abstract

We investigated genetic relationships among temporally replicated collections of summer Chinook from the Wenatchee River, Methow River, and Okanogan River in the upper Columbia River basin. Samples from the Eastbank Hatchery Wenatchee stock, Eastbank Hatchery - MEOK stock, and Wells Hatchery were also included in the analysis. Samples of natural- and hatchery-origin summer Chinook were analyzed and compared to determine if the supplementation program has had any impacts to the genetic structure of these populations. We also calculated the effective number of breeders for collection locations of natural- and hatchery-origin summer Chinook from 1993 and 2008. In general, population differentiation was not observed among the temporally replicated collection locations. A single collection from the Okanogan River (1993) was the only collection showing statistically significant differences. The effective number of breeders was not statistically different from the early collection in 1993 in comparison to the late collection in 2008. Overall, these analyses revealed a lack of differentiation among the temporal replicates from the same locations and among the collection from different locations, suggesting the populations have been homogenized or that there has been substantial gene flow among populations. Additional comparisons among summer-run and fall-run Chinook populations in the upper Columbia River were conducted to determine if there was any differentiation between Chinook with different run timing. These analyses revealed pairwise Fst values that were less than 0.01 for the collections of summer Chinook to collections of fall Chinook from Hanford Reach, lower Yakima River, Priest Rapids, and Umatilla. Collections of fall Chinook from Crab Creek, Lyons Ferry Hatchery, Marion Drain, and Snake River had pairwise Fst values that were higher in comparison to the collections of summer Chinook. The consensus clustering analysis did not provide good statistical support to the groupings, but did show relationships among collections based on geographic proximity. Overall the summer and fall run Chinook that have historically been

spawned together were not differentiated while fall Chinook from greater geographic distances were differentiated.

## Introduction

The National Marine Fisheries Service (NMFS) recognizes 15 Evolutionary Significant Units (ESU) for Chinook salmon (Oncorhynchus tshawytscha) (Myers et al. 1998). The summer Chinook from the upper Columbia River are included in the Upper Columbia River Summer- and Fall-Run ESU, which encompasses all late-run (summer and fall), ocean-type Chinook salmon from the mainstem Columbia River and its tributaries (excluding the Snake River) between Chief Joseph and McNary Dams (Waknitz et al. 1995). Waknitz et al. (1995) concluded that due to high total abundance this ESU was not likely to become at risk from extinction. Yet, a majority of natural spawning activity was in the vicinity of Hanford Reach, and it was unclear whether natural production was selfsustaining given the vast summer Chinook artificial propagation efforts (Waknitz et al. 1995). Additionally, the Biological Review Team expressed concern about potential consequences to genetic and life-history traits from an increasing contribution of hatchery fish to total spawning escapement (Waknitz et al. 1995).

Artificial propagation of ocean-type Chinook from the middle/upper Columbia has been continuous since the implementation of the Grand Coulee Fish Maintenance Project (GCFMP) in 1939 (Myers et al. 1998). The US Fish and Wildlife Service established three hatchery programs for summer/fall Chinook during the GCFMP, Leavenworth NFH, Entiat NFH, and Winthrop NFH. The Washington Department of Fisheries (now Washington Department of Fish and Wildlife) followed with hatchery programs at Rocky Reach (1964), Wells Dam (1967), Priest Rapids (1974), and Eastbank (1990) facilities. Currently, only Leavenworth NFH and Winthrop NFH are not producing summer/fall Chinook. Entiat NFH has resumed production of summer/fall Chinook (Wells FH Stock) in 2009 and released their first yearling summer Chinook smolts in 2010. Since

1941, over 200 million ocean-type Chinook salmon have been released into the middle Columbia River Basin (Myers et al. 1998). Initially, the hatchery programs differentiated between early returning fish (i.e., stream-type) and later returning fish (i.e., ocean-type), but no distinction was made regarding the "summer" and "fall" components of the ocean-type stocks (Waknitz et al. 1995). Therefore, all Chinook salmon now migrating above Rock Island Dam descend from not only a mixture between different stocks from the basin, but also a mixture between the endemic summer and fall life histories. While hatchery protocols have been modified of late to maintain discreet summer and fall Chinook hatchery stocks (Utter et al. 1995; see also HGMP), physical evidence and genetic data suggests that summer and fall Chinook may have become homogenized. During the 1970's and 80's, given coded-wire tag recoveries, summer-run Chinook originating from above Rock Island Dam were believed to have spawned extensively with Hanford Reach and Priest Rapids Hatchery fish (Chapman 1994). Stuehrenberg et al. (1995) reported that $10 \%$ of their radio tagged summer Chinook were occupying typical fall-run spawning habitat on the mainstem Columbia river, and $25 \%$ of fall fish released from Priest Rapids were recovered as summers at (or above) Wells Hatchery. Genetic data reported by Marshall et al. (1995) and Waknitz et al. (1995) corroborate these observations, as genetic distances observed between summer and fall Chinook within the Upper Columbia River Summer- and Fall-Run ESU were essentially zero.

In response to the need for evaluation of the supplementation hatchery programs, both a monitoring and evaluation plan (DCPUD 2005; Murdoch and Peven 2005) and the associated analytical framework (Hays et al. 2006) were developed for the Habitat Conservation Plan's Hatchery Committee through the joint effort of the fishery co-managers (CCT, NMFS, USFWS, WDFW, and YN) and Chelan County and Douglas County PUDs. These reports outline 10 objectives to be applied to various species assessing the impacts of hatchery operations mitigating the operation of Wells, Rocky Reach, and Rock Island hydroelectric projects. The present monitoring and evaluation study plan differs
in scope from previous monitoring and evaluation projects proposed by WDFW Molecular Genetics Lab, in that it does not investigate a single watershed, but instead will encompass all summer Chinook stocks from the upper Columbia River including the three supplementation (Wenatchee, Methow, and Okanogan) and the harvest augmentation program (Wells summer Chinook). The objectives of this study were to determine if genetic diversity, population structure, and effective population size have changed in natural spawning populations as a result of the hatchery programs.

## Materials and Methods

## Collections

A total of 2,416 summer Chinook were collected from tributaries in the upper Columbia River basin and were analyzed (Table 1). Two collections of naturalorigin summer Chinook from 1993 (prior to the supplementation program) were taken from the Wenatchee River Basin and were compared to collections of hatchery and natural-origin from 2006 and 2008 that were post-supplementation. Two pre-supplementation collections from the Methow River (1991 and 1993) were compared to post-supplementation collections from 2006 and 2008. Three pre-supplementation collections from the Okanogan River Basin (1991, 1992, and 1993) were compared with post-supplementation collections from 2006 and 2008. A collection of natural-origin summer Chinook from the Chelan River was also analyzed. Additionally, hatchery collections from Eastbank Hatchery (Wenatchee and MEOK stock) and Wells Hatchery were analyzed and compared to the in-river collections. Summer Chinook data (provided by the USFWS) from the Entiat River was also used for comparison. Lastly, data from eight collections of fall Chinook was compared to the collections of summer Chinook.

## Laboratory Analyses

All laboratory analyses were conducted at the WDFW Genetics Laboratory in Olympia, Washington. Genomic DNA was extracted by digesting a small piece of fin tissue using the nucleospin tissue kits obtained from Macherey-Nagel following the recommended conditions in the user manual. Extracted DNA was eluted with a final volume of $100 \mu \mathrm{~L}$.

Genotype information was generated using thirteen microsatellite markers following standard laboratory protocols and analysis methods. Descriptions of the loci assessed in this study and polymerase chain reaction (PCR) conditions are given in Table 2. PCR reactions were run with a thermal profile consisting of: denaturation at $95^{\circ} \mathrm{C}$ for 3 min , denaturation at $95^{\circ} \mathrm{C}$ for 15 sec , anneal for 30 sec at the appropriate temperature for each locus (Table 2), extension at $72^{\circ} \mathrm{C}$ for 1 min, repeat cycle (steps 2-4), final extension at $72^{\circ} \mathrm{C}$ for 30 minutes. PCR products were then processed with an ABI-3730 DNA Analyzer. Genotypes were visualized with a known size standard (GS500LIZ 3730) using GENEMAPPER 3.7 software. Alleles were binned in GENEMAPPER using the standardized allele sizes established for the Chinook GAPS dataset (Seeb et al. 2007).

## Within-collection Statistical Analyses

Allele frequencies were calculated with CONVERT (version 1.3, Glaubitz 2003). Hardy-Weinberg proportions for all loci within each collection were calculated using GENEPOP (version 3.4, Raymond and Rousset 1995). Heterozygosity (observed and expected) was computed for each collection group using GDA (Lewis and Zaykin 2001).

Allelic richness and FIS (Weir and Cockerham 1984) inbreeding coefficient were calculated using FSTAT (version 2.9.3.2, Goudet 2001). Linkage disequilibrium for each pair of loci in each collection was calculated using GENEPOP v 3.4 (10,000 dememorizations, 100 batches, and 5,000 iterations per batch). Pairwise estimates of genetic differentiation between collection groups were
calculated using GENEPOP (version 3.4, Raymond and Rousset 1995). Statistical significance for the tests of Hardy-Weinberg proportions, linkage disequilibrium, and genotypic differentiation was evaluated using a Bonferroni correction of $p$-values to account for multiple, simultaneous tests (Rice 1989).

## Between-collection Statistical Analyses

Pairwise Fst estimates were computed to examine population structure among collections using GENETIX (version 4.03, Belkhir et al. 2001). This estimate uses allelic frequency data and departures from expected heterozygosity to assess differences between pairs of populations.

We used PHYLIP (version 3.5c, Felsenstein 1993) to calculate Cavalli-Sforza and Edwards (1967) pairwise chord distances between collections. Bootstrap calculations were performed using SEQBOOT followed by calculations of genetic distance using GENDIST. The NEIGHBOR-JOINING method of Saitou and Nei (1987) was used to generate the dendrograms and CONSENSE to generate a final consensus tree from the 1,000 replicates. The dendrogram generated in PHYLIP was plotted as an unrooted radial tree using TREEVIEW (version 1.6.6, Page 1996).

## Effective Number of Breeders

The effective number of breeders ( N b ) was estimated for pre- and postsupplementation program collections (where possible) to investigate whether hatchery programs had affected that genetic metric over the operational period. Wang (2009) derived an equation for effective size ( $\mathrm{N}_{\mathrm{e}}$ ) as a function of the frequency of nested full-sib and half-sib families in a random collection of individuals.

$$
\begin{equation*}
\frac{1}{N_{e}}=\frac{1+3 \alpha}{4}\left(Q_{1}+Q_{2}+2 Q_{3}\right)-\frac{\alpha}{2}\left(\frac{1}{N_{1}}+\frac{1}{N_{2}}\right) \tag{equation10}
\end{equation*}
$$

Where $\alpha$ is a measure of the deviation of genotype frequencies from HardyWeinberg expectation (equivalent to Wright's (1969) Fis), $Q_{i}$ are the probabilities that a pair of offspring are paternal half sibs, maternal half sibs, or full sibs, respectively, and $\mathrm{N}_{1}$ and $\mathrm{N}_{2}$ are the number of male and female parents that generation, respectively. Genetic parameters (i.e., sibship distributions) were estimated for summer Chinook collections using algorithms implemented in COLONY (Jones and Wang 2009). To be clear, Wang's (2009) method as implemented here will estimate $\mathrm{N}_{\mathrm{b}}$, given multi-locus genotypes from each collection were partitioned by brood year for this analysis. To obtain an estimate of $N_{e}$ each $N_{b}$ value must be multiplied by the mean generation time of that population.

## Results

## Collections

A total of 2,350 individuals from 32 collections of temporally replicated samples (six locations) were analyzed (Table 1). Temporally replicated collections of hatchery and natural-origin samples were from the Wenatchee, Methow, and Okanogan Rivers. Temporally replicated hatchery-origin summer Chinook were from Wells Hatchery, Eastbank Hatchery - Wenatchee stock, and Eastbank Hatchery - Methow/Okanogan (MEOK) stock. A total of 232 of those individuals were excluded from any analyses because they failed to amplify at nine or more loci. Data for remaining 2,118 individuals were analyzed to assess differences between temporally replicated natural- and hatchery-origin summer Chinook for each location and to compare the differences among the different collection locations. Summer Chinook data from the temporally replicated collection locations were then combined and compared to fall Chinook data from the GAPS v.3.0 dataset.

## Statistical Analyses

The population statistics (Hardy-Weinberg equilibrium and Fis) calculated for each of the 32 temporally replicated collection locations were consistent with neutral expectations (i.e., no associations among alleles). Three collections did have a single locus that did not meet expectations (Wenatchee hatchery-origin 2006, Wells hatchery 2006, and Okanogan hatchery-origin 2009). Based on these results we suggest the collections represented randomly breeding groups and were not comprised of mixtures of individuals from different genetic source populations.

Population differentiation was assessed for each of the temporally replicated collections from within each location (Table 3). This analysis revealed the only significant difference observed within a collection location pertained to the collection from 1993 Okanogan River natural-origin samples. Because of the significant difference of this collection to the other temporal replicates it was not included in further analyses.

Given the absence of genetic differentiation observed among the temporally replicated collections, the 32 collections from the Wenatchee, Methow, and Okanogan River were combined to form three location-specific collections for analysis. Population differentiation metrics were compared among the composite Wenatchee, Methow, and Okanogan collections and eight other location-specific collections ( 11 locations total). Comparing all collections, there were a total of 39 significant genic test comparisons out of a total 496 (Table 4). Thirty-eight of the 39 statistically significant pairwise differences pertained to the Okanogan River and 2006 Wells Hatchery collections (Table 4). Fst results are described further below.

Within-collection genetic metrics were estimated for the 11 location-specific collections of summer Chinook from the upper Columbia River, in addition to eight collections of fall Chinook (Table 1). The population statistics (HardyWeinberg equilibrium and Fis) calculated for these collections of summer and fall

Chinook were also consistent with neutral expectations. The collection from Lyons Ferry Hatchery had one locus that did not meet expectations and the collections from Crab Creek and Marion Drain both had three loci that did not meet expectations.

The hatchery collections in general had a higher percentage of significantly linked loci; however the observed genetic diversity were similar for the natural and hatchery-origin collections. Analysis of allelic richness was based on 11 individuals per collection, the minimum number of individuals across all collections with complete multilocus genotypes. The largest number of linked loci occurred in the Crab Creek, Entiat River, and Okanogan natural-origin collections. Allelic richness was on average lower in the collections of summer Chinook (10.7) collections in comparison to the collections of fall Chinook (11.0).

Pairwise Fst (Table 4) estimates revealed low levels of differentiation, where all observed Fst values between the collections of summer Chinook were lower than 0.0096 . There were 15 out of 28 comparisons between collections of summer Chinook that were significantly different from zero and occurred primarily from comparisons of the Okanogan River (hatchery and natural-origin) and Wells Hatchery to all other collections. The collection of Eastbank Hatchery - MEOK stock was differentiated from the Wenatchee River natural-origin and Entiat River collections. The collection from the Chelan River had a small sample size of 23 individuals and only differentiated from the Eastbank Hatchery - MEOK stock. Fst estimates regarding pairwise comparisons between each of four fall Chinook collection locations (Crab Creek, Lyons Ferry Hatchery, Marion Drain, and Snake River) to all other collections were significantly different from zero (Table 5). Pairwise comparisons for three other fall Chinook collections (Hanford Reach, lower Yakima River, and Umatilla River) to the collections of summer Chinook were significantly different from zero (Table 6). The only fall Chinook collection that was not significantly differentiated from all of the summer Chinook was Priest Rapids.

The relative genetic relationships among the test groups were assessed using the consensus clustering analysis (Figure 1). Statistical support for the dendrogram topology (i.e., tree shape) was low regarding the branching that separated the collections of summer Chinook from the upper Columbia River. The collections of fall Chinook; however were supported with bootstrap support over $76 \%$ with the exception of three collections (lower Yakima River, Crab Creek, and Umatilla River). In other words, 760 of the 1000 bootstrap replicates supported the placement of the node separating summer and fall collections. The collection from the Chelan River had bootstrap support of 68\%; however the sample size for that collections was small $(\mathrm{N}=23)$. Even though the bootstrap support was low among the collections of summer Chinook there was concordance between geography and genetic distance.

Where comparisons were possible between pre- and post-supplementation program collections, the effective number of breeders $\left(\mathrm{N}_{\mathrm{b}}\right)$ estimated to have comprised those collections were slightly lower for contemporary (2008) collections; however in all cases the 95\% confidence intervals overlapped between historical and contemporary collections, suggesting statistical equivalency. Regarding Wenatchee River collections, the point estimates of $\mathrm{N}_{\mathrm{b}}$ ranged from 134 (08FU) to 190 (93DD), where all collections had overlapping confidence intervals (Table 7). The upper bound of the 1989 brood year for collection 93DD was very large, suggesting the sample size was insufficient for properly inferring the sibship distribution within the collection. Comparing the Okanogan natural collections 93ED and 08GA, the estimated Nb were 142 (CI 102 - 203) and 127 (CI 92 - 180), respectively. For the Eastbank Hatchery MEOK stock comparisons, the $\mathrm{N}_{\mathrm{b}}$ estimated for the 93DF collection was 171 (CI 129 - 229), as compared to the 166 ( $\mathrm{Cl} 126-226$ ) estimated for collection 08 MO . In all cases, the estimated $\mathrm{N}_{\mathrm{b}}$ can be converted to effective population size $\left(\mathrm{N}_{\mathrm{e}}\right)$ by multiplying the estimate by the mean generation time.

## Discussion

The collections of summer Chinook populations from the upper Columbia River are of interest because census sizes are reduced below historic levels and are the subject of mitigation and supplementation hatchery programs. Concern over the impacts of hatchery supplementation programs on the genetic integrity of natural-origin populations led to our primary objective, which was to evaluate genetic metrics for temporally replicated collections of summer Chinook in the upper Columbia River pre and post hatchery supplementation. A similar analysis by Kassler and Dean (2010) was conducted on spring Chinook in the Tucannon River to evaluate the effects of a supplementation and captive brood program on natural-origin stocks. Additionally, upper Columbia River spring Chinook supplementation programs (Blankenship et al. 2007; Small et al. 2007), spring and fall Chinook populations in the Yakima Basin (Kassler et al. 2008), and a potentially unique population of fall Chinook in Crab Creek (Small et al. 2010) have been evaluated. In the present analysis of summer Chinook populations, collections of pre- and post- supplementation summer Chinook were collected from the Wenatchee River, Methow River, and Okanogan River Basins and analyzed to determine if the genetic profile has changed as a result of the supplementation program. Analysis was then conducted on the collections of summer run to compare the fall run Chinook collections in the upper Columbia River basin.

Allozyme analyses of these three summer run Chinook stocks in the upper Columbia River have identified that each stock was distinct, with a closer relationship detected between the Wenatchee and Methow Rivers (WDF and WDW 1993, Marshall 2002). Wenatchee summer Chinook are thought to be a mixture of native summer Chinook and Chinook from the Grand Coulee Fish Maintenance Project (GCFMP). The goal of the GCFMP project between 1939 and 1943 was to trap migrating Chinook salmon at Rock Island dam ( 75 miles below Grand Coulee) and homogenize the populations, which reduced the
genetic uniqueness of the distinct tributary populations present in the upper Columbia River.

We found allele frequencies for individual temporally replicated hatchery- and natural-origin collection locations of adult summer Chinook were not significantly different from that expected of a single underlying population, except for one collection (1993 Okanogan natural-origin; Table 3). This collection was differentiated to the Okanogan collections in 2006 and 2008; however it was not differentiated from the collection in 1992. The Okanogan collection from 1992 was also not differentiated to any other collection; therefore the difference in the collection from Okanogan 1993 was likely not an indication of genetic change from pre supplementation to post supplementation. The collection was however dropped from further analyses so as to not confuse interpretation of results. The lack of allelic differentiation observed among the temporally replicated collections was interpreted as the genetic metrics from each location in the early 1990's did not differ from the samples collected in 2008. Spanning a few generations, allele frequencies are not expected to change for large populations at genetic equilibrium. In contrast, changes in allele frequencies of small populations may occur due to the stochastic sampling of genes from one generation to the next (i.e., genetic drift).

A second round of analyses was conducted to evaluate the genetic relationships of the summer run collections (temporal collections were combined) with data from the Entiat River, Chelan River, and eight collections of fall Chinook. Assessment of the relationship between the summer run collections in comparison to each other provided very little evidence of genetic differentiation between these collections. While population differentiation did show some significant differences between the Okanogan River and Wells Hatchery collections, all of the pairwise Fst values were below 0.003. Meaning that a very small proportion of the observed genetic variation could be attributed to restrictions in gene flow (i.e., population structure)

The comparison of the hatchery-origin collections revealed a lack of differentiation between the Eastbank Hatchery - Wenatchee stock, Eastbank Hatchery - MEOK stock, and the Wells Hatchery (with exception of the 2006 collection). The genetic similarity or low level of genetic differentiation among these stocks suggests that there has been an integration of natural- and hatchery-origin summer Chinook in the upper Columbia River or a lack of ancestral genetic difference. The difference of the 2006 Wells Hatchery collection to the other collections is most likely a result of sampling effect because of the lack of differentiation among the stocks in the basin. If the 2006 collection had been mixed from different sources of summer Chinook there would not be a detectable level of differentiation as was seen with the 2006 sample.

The analyses to compare summer and fall Chinook collections provided some understanding on the genetic relationships of Chinook with different run timings in the upper Columbia River basin. Historically, the hatchery programs in the upper Columbia River were separated into groups of the early returning fish (i.e., stream-type) and later returning fish (i.e., ocean-type), but the programs did not sort individuals identified as "summer" or "fall" stocks (Waknitz et al. 1995). Now all Chinook salmon that are migrating above Rock Island Dam descend from a mixture of different stocks from the upper Columbia River basin, but also a mixture between the endemic summer and fall life histories.

Small et al. (2010) conducted an analysis on summer run and fall run Chinook in the upper Columbia River and concluded that Crab Creek Chinook in the upper Columbia River were genetically distinct to all other fall and summer run Chinook stocks that were analyzed. They did note a departure from Hardy Weinberg expectation as a result of a null allele at the microsatellite locus Ogo-4 and a higher linkage disequilibrium value due to the inclusion of family groups in one of their samples. Kassler et al. (2008) found differentiation among spring and fall Chinook populations in the Yakima River.

The tests of pairwise Fst indicated a very low level of genetic differentiation (less than one percent difference) between collections of summer-run Chinook and fall-run Chinook. The range of pairwise Fst values for comparisons between the summer run and fall run collections was $0.0016-0.0248$. The larger values from the range were associated to the collections from Crab Creek, Lyons Ferry Hatchery, and Marion Drain. Studies by Kassler et al. (2008) and Small et al. (2010) have documented differences among the populations of these collections to others within the upper Columbia River basin. The low pairwise Fst values between Priest Rapids and Hanford Reach collections and the summer run collections were not surprising because summer-run Chinook originating from above Rock Island Dam were believed to have spawned extensively with Hanford Reach and Priest Rapids Hatchery fish during the 1970's and 80's (Chapman 1994). The lack of differentiation among the summer and fall stocks in the Columbia River was also identified by Utter et al. (1995) and the HGMP where they state physical evidence and genetic data suggests that summer and fall Chinook may have become homogenized.

Despite low levels of statistical bootstrap support for dendrogram topology (i.e., tree shape), there was concordance observed between geographic location and the genetic relationships among the summer and fall Chinook populations. The collections from the Okanogan (hatchery and natural-origin) did separate out with collections from Wells Dam Hatchery, Entiat River, and Eastbank Hatchery MEOK stock, and were next to a group of the Methow and Wenatchee collections. The fall Chinook populations are also separated to the summer collections and the position of all but three of these collections (lower Yakima River, Crab Creek, and Umatilla River) were statistically supported. The geographic proximity of the fall collections seemed to follow the observed pattern in this dendrogram. The relationship of the Snake River and Lyons Ferry Hatchery in proximity to the collection from Marion Drain was not surprising while
the relationship between Priest Rapids and Hanford Reach was easily a result of the stocking practices of fall Chinook in the 1970 and 1980's.

A secondary objective of this study was to determine if the effective population size of upper Columbia River summer Chinook populations had changed over time due to supplementation efforts. We observed that the number of effective breeders in the collections from 1993 and 2008 has not changed thus providing reason to believe that the genetic diversity of summer Chinook in the upper Columbia River has not been altered through the supplementation program.

## Acknowledgements

Chelan County PUD, Grant County PUD, and Washington State General Funds provided funding for this project. Cherril Bowman (WDFW - Molecular Genetics Laboratory) processed samples in the laboratory. Maureen (Mo) Small provided data for some collections and discussion of the analyses. USFWS provided data from the Entiat River.

Table 1. Samples of adult hatchery- and natural-origin summer and fall Chinook that were analyzed from the upper Columbia River. Total number of individuals that were analyzed / individuals with data for 9 or more loci that were included in the analysis. Collection statistics (allelic richness, linkage disequilibrium (before and after Bonferroni correction), $\mathrm{F}_{\text {IS }}$, heterozygosity $\left(H_{O}\right.$ and $\left.H_{E}\right)$ ) and $p$-values for deviations from Hardy-Weinberg equilibrium (HWE). P-values were defined as significant after implementation of Bonferroni correction for multiple tests (Rice 1989).

Summer Chinook Spawning Ground Surveys in the Methow River Basin and Chelan River, 2016

BioAnalysts, Inc."'
4725 North Cloverdale Road, Ste. 102
Boise ID 83713

March 10, 2017

## To: Chelan and Grant Public Utility Districts

From: Denny Snyder and Mark Miller
Re: 2016 Summer Chinook Spawning Ground Surveys in the Methow Basin and Chelan River.
The purpose of this memo is to provide information on the supplemented natural spawning population of summer Chinook in the Methow and Chelan River basins. This work is part of a larger effort focused on monitoring and evaluating Grant and Chelan PUDs' hatchery supplementation programs. The tasks and objectives associated with implementing Grant and Chelan PUDs' Hatchery M\&E Plan for 2016 are outlined in Hillman et al. (2013). In 2016, The Okanogan Basin was surveyed by the Colville Confederated Tribes (CCT).

## METHODS

Spawning ground surveys were conducted by foot and raft beginning the third week of September and ending late-November. We did not use aerial surveys on the Methow River because past work has demonstrated that ground counts were more accurate than aerial surveys (Miller and Hillman 1997). Ground surveys were used to provide more accurate counts and a complete census of Chinook redds within their spawning distribution. Observers floated or walked through sampling reaches and recorded the location and numbers of redds each week (see Figures 1 and 2). Observers recorded the date, water temperature, river mile, and prepared a drawing of the area where redds were located. A different symbol was used each week to record the number of new and incomplete redds.

To maintain consistency, at least one observer surveyed the same stream reach on successive dates. In areas where numerous summer Chinook spawn, we constructed detailed maps of the river and used the cell-area-method (Hamilton and Bergersen 1984) to identify the number of redds within each cell. Cells were bound by noticeable landmarks along the banks (e.g., bridges or trees) or at stream habitat boundaries (e.g., transitions between pools and riffles). The number of redds were then recorded in the corresponding grid on the map. When possible, observers estimated the number of redds in a large disturbed area by counting females that defended redds. We assumed that the area or territory defended by a female was one redd.

Figure 1. Summer Chinook survey reaches on the Methow River, 2016,

Figure 2. Summer Chinook survey areas on the Chelan River, 2016.

Spawning escapement was estimated as the number of redds times the sex ratio observed at Wells Dam during broodstock collection. In 2016, reach M1 experienced some clarity issues during spawning surveys. Turbidity noticeably increased during rainstorm events and was probably influenced by the Carlton Complex Fires and landslides that occurred in 2014.

Carcasses of summer Chinook were sampled to describe the spawning population. Biological data collection included: scale samples for age analysis, length measurements (POH and FKL), sex, egg voidance, marks, and presence of PIT tags. These data will be used to assess length-at-age, size-at-age, egg voidance, origin (hatchery or naturally produced), and stray rates. No DNA samples were collected on summer Chinook this year. In this report, we only report the number of redds counted in the Okanogan Basin.

## RESULTS

## Methow

There were 1,115 summer Chinook redds counted within seven reaches on the Methow River (Table 1). Most redds ( $81 \%$ ) were located in reaches from the mouth to the town of Twisp (M1M3). Estimated escapement based on expansion of redd counts from the sex-ratio observed at Wells Dam during broodstock collection indicates that 2,241 summer Chinook ( 1,115 redds x 2.01 fish/redd) spawned in the Methow River.

Table 1. Number of summer Chinook redds observed each week within the Methow River, 2016. Dashes (--) indicate that no survey occurred.

Time of spawning was assessed as the number of new redds counted each week in the Methow River. Spawning began the last week of September, peaked in early October, and ended the third week of November (Figure 3). Stream temperatures in the Methow River varied from 10.5-11.0 ${ }^{\circ} \mathrm{C}$ in September when spawning began. Spawning peaked the first week of October in Reach M7, while peak spawning occurred in reaches M2-M6 the second week of October. Spawning peaked
the fourth week of October in reach M1 (Table 1). This was the sixth highest redd count observed in the last 26 years for the Methow River (Appendix A).

Time of Spawning
Methow River

Figure 3. Number of new redds counted each week from late September to late-November in the Methow River, 2016. The figure shows the beginning, peak, and end of spawning for summer Chinook in the Methow River compared to a 25 -year average (1991-2015).

There were 587 summer Chinook salmon carcasses sampled within the seven reaches on the Methow River (Table 2). The presence or absence of an adipose fin could not be determined on one fish. Twenty-six percent of the fish returning to the Methow River were sampled based on the estimated escapement of 2,241 summer Chinook. Ad-clipped hatchery fish made up $32 \%$ and naturally produced fish (adipose fin present) made up $68 \%$ of the fish sampled (Table 2).

Table 2. Number and percent of hatchery (ad-clipped) and naturally produced (ad-present) summer Chinook sampled in the Methow River, 2016.

| Reach | Location ( $\mathbf{R k m}$ ) | Ad-Clipped Hatchery |  |  |  | Naturally Produced |  |  |  | Reach <br> Total |

| M7 | 83.0-96.1 | 0 | 0 | 0 | 0 | 3 | 2 | 5 | 100 | 5 |
| Total |  | 72 | 114 | 186 | 32 | 172 | 228 | 400 | 68 | 586 |

[^53]Most (90\%) of the ad-clipped hatchery fish were located in reaches M1-M3, while naturally produced fish were sampled within all survey reaches (Figure 4). Naturally produced fish made up $100 \%$ of the fish sampled in upper reaches (M6 and M7). Female summer Chinook accounted for $58 \%$ of the fish sampled in 2016 (Table 2).

Figure 4. Percent distribution of ad-clipped hatchery and naturally produced fish plotted against the percent distribution of redds observed in reaches on the Methow River, 2016.

Egg voidance was assessed by sampling spawned-out female carcasses. Based on 343 sampled female carcasses, average egg voidance was $98 \%$. Four females ( $1 \%$ ) died before spawning (i.e., they retained all their eggs).

## Chelan River

There were 448 redds counted in the Chelan River. This is the second highest redd count observed for summer Chinook in the Chelan River since 2000. The majority of spawning occurred in the powerhouse tailrace ( $46 \%$ ), habitat channel ( $24 \%$ ), and in the Columbia River tailrace ( $16 \%$ ) (Table 3). Estimated escapement based on expansion of counts from the sex-ratio observed at Wells Dam during broodstock collection indicates that 900 summer Chinook (448 redds x 2.01 fish/redd) spawned in the Chelan River.

Table 3. Number of summer Chinook redds observed each week within the Chelan and Columbia rivers, 2016. Dashes (--) indicate that no survey occurred.

| Reach | Location (Rkm) | Sep Oct |  |  |  |  |  | Nov Dec |  |  |  |  | Total | Percent |

Time of spawning was assessed as the number of new redds counted each week in the Chelan River. Spawning activity began the first week of October and peaked two weeks later (Figure 5). Spawning ended the third week of November. An exceptionally high redd count in 2013 (792 redds) and late spawning in 2014 currently influence the average time of spawning. As more years of information are collected, average time of spawning will likely not appear bimodal.

Time of Spawning

Figure 5. Number of new summer Chinook redds counted each week in the Chelan River from late September to mid-November. The figure displays the beginning, peak, and end of spawning for summer Chinook in the Chelan River in 2016 compared to a 4 -year average (2012-2015).

There were 253 summer Chinook carcasses sampled in the Chelan River (Table 4). Twenty-eight percent of the summer Chinook returning to the Chelan River were sampled based on the estimated spawning escapement of 900 fish. Based on the absence of their adipose fin, hatchery fish made up $52 \%$ and naturally produced (ad-present) fish made up $48 \%$ of the fish examined. Females made up 73\% of the carcasses examined (Table 4).

Table 4. Number and percent of hatchery (ad-clipped) and naturally produced (ad-present) summer Chinook collected in the Chelan River, 2016. The origin of one fish sampled could not be determined in the Chelan River.

| Reach | Location <br> (Rkm) | Ad-Clipped Hatchery |  |  |  | Naturally Produced |  |  |  | Reach <br> Total |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Female | Total | Percent | Male | Female | Total | Percent | 70 |  |

| Pool | 10 | 15 | 25 | 73 | 3 | 6 | 9 | 4 | $\mathbf{6 3}^{1}$ |  |
| Habitat Channel | 9 | 26 | 35 | 56 | 9 | 19 | 28 | 44 | $\mathbf{4 8}$ | $\mathbf{2 5 3}$ |
| Total | $\mathbf{4 0}$ | $\mathbf{9 2}$ | $\mathbf{1 3 2}$ | $\mathbf{5 2}$ | $\mathbf{2 8}$ | $\mathbf{9 2}$ | $\mathbf{1 2 0}$ |  |  |  |

${ }^{1}$ Origin of one female carcass in habitat channel could not be assigned.

The distribution of ad-clipped hatchery fish and naturally produced fish varied within the Chelan River (Figure 6). A disproportionate number of fish (compared to redds counts) were sampled in the Columbia River tailrace. This likely occurred because carcasses drifted from upstream spawning areas and settle in the Columbia River tailrace. More hatchery fish were sampled in the habitat channel and pool upstream. Conversely, more wild fish were sampled in the powerhouse tailrace than hatchery summer Chinook.

## Carcass Distribution

Figure 6. Percent distribution of ad-clipped hatchery and naturally produced fish plotted against the percent distribution of redds observed in reaches on the Chelan River, 2016.

In 2016, about 50 summer Chinook were collected as broodstock from the pool area upstream from the habitat channel.

Mean egg voidance assessed from 181 female carcasses was $81 \%$. Egg voidance from four females could not be determined and seventeen females (17\%) died before spawning. No Coho were sampled in 2016.

## Okanogan Basin

In 2016, CCT conducted summer Chinook surveys in the Okanogan River basin. A total of 5,276 redds were counted in the Okanogan Basin (Personal Communication, Andrea Pearl, CCT).

${ }^{1 .}$ The redd count is for the entire Okanogan Basin (Similkameen + Okanogan rivers).

[^0]:    ${ }^{1}$ Throughout this document, "HxH" refers to hatchery-origin by hatchery-origin crosses and "WxW" refers to natural-

[^1]:    ${ }^{2}$ In this report, we use two methods of describing age. One is termed the "European Method." This method has two digits, separated by a period. The first digit represents the number of winters the fish spent in freshwater before migrating to the sea. The second digit indicates the number of winters the fish spent in the ocean. For example, a fish designated as 1.2 spent one winter in freshwater and two in the ocean. A fish designated as 0.3 migrated to the ocean

[^2]:    ${ }^{3}$ Expansion factor $=(1+($ number of males/number of females $))$.
    ${ }^{4}$ Adult sockeye that were tagged at Bonneville Dam and detected at Tumwater Dam were included in the markrecapture analyses.

[^3]:    ${ }^{6}$ Expansion factor $=(1+($ number of males/number of females $))$.

[^4]:    ${ }^{7}$ According to authorized annual take permits, PNI is calculated using the PNI approximate equation 11 (HSRG 2009; Appendix A). However, in this report, we used Ford's (2002) equations 5 and 6 with a heritability of 0.3 and a selection strength of three standard deviations to calculate PNI (C. Busack, NOAA Fisheries, 21 March 2016, provided the model for calculating PNI). This approach is more accurate than using the PNI approximate equation.

[^5]:    ${ }^{8}$ It is important to point out that because of fish size differences among rearing tanks or raceways, fish PIT tagged in one tank or raceway may not represent untagged fish rearing in other tanks or raceways.

[^6]:    ${ }^{9}$ It is important to point out that because of fish size differences among rearing tanks or raceways, fish PIT tagged in one tank or raceway may not represent untagged fish rearing in other tanks or raceways.

[^7]:    ${ }^{10}$ In 2016, the natural-origin egg-take goal was not achieved, but the program egg-take goal was achieved.

[^8]:    ${ }^{11}$ Population carrying capacity $(K)$ should not be confused with habitat carrying capacity $(C)$, which is defined as the maximum population of a given species that a particular environment can sustain.

[^9]:    12 Expansion factor $=(1+($ number of males/number of females $))$.

[^10]:    ${ }^{13}$ Expansion factor $=(1+($ number of males/number of females $))$.

[^11]:    14 According to authorized annual take permits, PNI is calculated using the PNI approximate equation 11 (HSRG 2009; Appendix A). However, in this report, we used Ford's (2002) equations 5 and 6 with a heritability of 0.3 and a selection strength of three standard deviations to calculate PNI (C. Busack, NOAA Fisheries, 21 March 2016, provided the model for calculating PNI). This approach is more accurate than using the PNI approximate equation.

[^12]:    ${ }^{15}$ It is important to point out that because of fish size differences among rearing tanks or raceways, fish PIT tagged in one tank or raceway may not represent untagged fish rearing in other tanks or raceways.

[^13]:    ${ }^{16}$ Population carrying capacity $(K)$ should not be confused with habitat carrying capacity $(C)$, which is defined as the maximum population of a given species that a particular environment can sustain.

[^14]:    ${ }^{17}$ Expansion factor $=(1+($ number of males/number of females $))$.

[^15]:    18 According to authorized annual take permits, PNI is calculated using the PNI approximate equation 11 (HSRG 2009; Appendix A). However, in this report, we used Ford's (2002) equations 5 and 6 with a heritability of 0.3 and a selection strength of three standard deviations to calculate PNI (C. Busack, NOAA Fisheries, 21 March 2016, provided the model for calculating PNI). This approach is more accurate than using the PNI approximate equation.

[^16]:    ${ }^{19}$ It is important to point out that because of fish size differences among rearing tanks or raceways, fish PIT tagged in one tank or raceway may not represent untagged fish rearing in other tanks or raceways.

[^17]:    20 Given that juvenile spring Chinook were tagged with CWTs in the peduncle and were not ad-clipped, it is possible that field crews missed hatchery-origin adults on the spawning grounds because they did not know they were supposed to sample fish with adipose fins. Thus, this bias in carcass sampling may bias derived metrics such as spawning distribution of hatchery and naturalorigin fish, spawn timing of hatchery and natural-origin fish, age at maturity, size at maturity, contributions to fisheries, HOR, NOR, HRR, NRR, PNI, straying, and SARs.

[^18]:    ${ }^{21}$ It is important to point out that because of fish size differences among rearing net pens, tanks, or raceways, fish PIT tagged in one pen, tank, or raceway may not represent untagged fish rearing in other pens, tanks, or raceways.

[^19]:    ${ }^{22}$ Population carrying capacity $(K)$ should not be confused with habitat carrying capacity $(C)$, which is defined as the maximum population of a given species that a particular environment can sustain.

[^20]:    ${ }^{23}$ Expansion factor $=(1+($ number of males/number of females $))$.

[^21]:    24 According to authorized annual take permits, PNI is calculated using the PNI approximate equation 11 (HSRG 2009; Appendix A). However, in this report, we used Ford's (2002) equations 5 and 6 with a heritability of 0.3 and a selection strength of three standard deviations to calculate PNI (C. Busack, NOAA Fisheries, 21 March 2016, provided the model for calculating PNI). This approach is more accurate than using the PNI approximate equation.

[^22]:    ${ }^{25}$ Expansion factor $=(1+($ number of males/number of females $))$.

[^23]:    ${ }^{26}$ It is important to point out that because of fish size differences among rearing tanks or raceways, fish PIT tagged in one tank or raceway may not represent untagged fish rearing in other tanks or raceways.

[^24]:    ${ }^{27}$ Most of the production at Carlton Acclimation Pond is initial production, which terminated in 2013, and is not necessarily tied to hydro facility mortality. The balance of the production is the result of a swap between spring and summer Chinook. That is, Chelan PUD is currently producing summer Chinook at Carlton for Douglas PUD in exchange for Douglas PUD producing spring Chinook at the Methow Fish Hatchery for Chelan PUD.

[^25]:    ${ }^{28}$ Expansion factor $=(1+($ number of males/number of females $))$.

[^26]:    ${ }^{29}$ It is important to point out that because of fish size differences among rearing tanks or raceways, fish PIT tagged in one tank or raceway may not represent untagged fish rearing in other tanks or raceways.

[^27]:    ${ }^{30}$ It is important to point out that some summer Chinook were used for both the Methow and Okanogan programs in 2012 because of the availability of ripe adults at the time of spawning. In addition, some eyed-eggs were split between the two programs

[^28]:    ${ }^{31}$ Expansion factor $=(1+($ number of males/number of females $))$.

[^29]:    32 It is important to point out that because of fish size differences among rearing tanks or raceways, fish PIT tagged in one tank or raceway may not represent untagged fish rearing in other tanks or raceways.

[^30]:    ${ }^{33}$ Expansion factor $=(1+($ number of males/number of females $))$.

[^31]:    ${ }^{34}$ Non-associated releases are release groups not containing any coded-wire tagged fish.

[^32]:    35 The Regional Mark Information System (RMIS) indicates that one tag code was released into Lake Chelan. Interestingly, some of these fish have been reported in ocean and Columbia River fisheries.

[^33]:    ${ }^{36}$ It is important to point out that because of fish size differences among rearing tanks or raceways, fish PIT tagged in one tank or raceway may not represent untagged fish rearing in other tanks or raceways.

[^34]:    ${ }^{1}$ Unnamed tributary that drains the eastside of Chiwawa Ridge. Its confluence with the Chiwawa River is about 1 mile ( 1.6 km ) downstream from the mouth of Phelps Creek.

[^35]:    ${ }^{2}$ The study period 1992-2016 includes only 24 years of sampling because there was no sampling in 2000.

[^36]:    ${ }^{3}$ The habitat use index was calculated as follows: Multiple channel use $\left.=\left(\operatorname{parr}_{m c} / \operatorname{parr}_{t}\right) /\left(\operatorname{area}_{m c} / \text { area }\right)_{t}\right)$, where parr $m c$ $=$ the number of parr counted in multiple channel habitat, $\operatorname{parr}_{t}=$ the total number of parr counted within all habitat types, are $_{m c}=$ the area of multiple channel habitat within the sampling frame, and area ${ }_{t}=$ the total area of the sampling frame. A multiple channel use index value of 1 would indicate that parr were uniformly distributed among habitat types and exhibited no preference for multiple habitat types. Values greater than 1 indicate use of multiple channels to a greater extent than the average, while scores between 0 and 1 indicate below-average use of multiple channel habitat.

[^37]:    ${ }^{4}$ The $\gamma$ parameter in the Gamma model was greater than 0 , which means that this model is nearly identical to the Ricker model.
    ${ }^{5}$ In these analyses, we are calculating "population" carrying capacity $(K)$, which is defined as the maximum equilibrium population size estimated with population models. This should not be confused with "habitat" carrying capacity $(C)$, which is defined as the maximum population of a given species that a particular environment can sustain.

[^38]:    ${ }^{6}$ Because there are no estimates for probability of detecting bull trout with daytime underwater observation methods in the Chiwawa River basin, we could not adjust bull trout numbers based on detectability. Therefore, the numbers reported in this report likely underestimate the "true" number of bull trout in the survey area.

[^39]:    ${ }^{1}$ Includes the lower 0.2 miles of Minnow Creek.
