# YAKIMA/KLICKITAT FISHERIES PROJECT MONITORING AND EVALUATION Yakima Subbasin 

PROJECT NUMBER 1995-063-25
Report covers work performed under BPA contract \#00056662 REL 185
Report was completed under BPA contract \#00056662 REL 198

FINAL REPORT
For the Performance Period
May 1, 2019 through April 30, 2020
August 10, 2020

Joe Blodgett, Project Coordinator
Mark Johnston, Research Scientist/Project Lead Bill Bosch, Research and Data Coordinator/Editor

Yakima/Klickitat Fisheries Project

THE CONFEDERATED TRIBES AND BANDS OF THE YAKAMA NATION
Toppenish, WA 98948

This report was funded by the Bonneville Power Administration (BPA), U.S. Department of Energy, as part of BPA's program to protect, mitigate, and enhance fish and wildlife affected by the development and operation of hydroelectric facilities on the Columbia River and its tributaries. The views in this report are the authors' and do not necessarily represent the views of BPA.

This report should be cited as follows:
Blodgett, J., M. Johnston, and B. Bosch (editors). 2020. Yakima-Klickitat Fisheries Project Monitoring and Evaluation - Yakima Subbasin, Final Report for the performance period May/2019-April/2020, Project number 1995-063-25, 378 electronic pages.

## Acknowledgements

Monitoring and evaluation efforts in the Yakima River Basin are the result of a cooperative effort by many individuals from a variety of agencies including the Yakama Nation Fisheries Program, the Washington Department of Fish and Wildlife, the United States Fish and Wildlife Service, the Columbia River Inter-Tribal Fish Commission, the National Oceanic and Atmospheric Administration Fisheries department as well as some consultants and contractors. We also wish to acknowledge and thank the Yakama Nation Tribal Council, U.S. Bureau of Reclamation, Yakima Subbasin Fish and Wildlife Recovery Board, Pacific States Marine Fisheries Commission, U.S. Forest Service Naches Ranger District, University of Idaho, Lars Mobrand and associates, University of Washington, and Central Washington University for their many contributions to this project including both recommendations and data services.

The core project team includes the following individuals: Mel Sampson, Joe Blodgett, Joe Hoptowit, Mark Johnston, Bill Bosch, Todd Newsome, Melinda Davis, Michael Porter, Sara Sohappy, Chris Frederiksen, Shubha Pandit, Andrew Matala, Daylen Isaac, Jim Matthews, and a number of technicians from the YN; Charles Strom and a number of assistants from the Cle Elum Supplementation and Research Facility; Michael Fiander and the crew at the Prosser Hatchery; Anthony Fritts, Gabe Temple, Christopher Johnson, and a number of assistants from the WDFW; We also receive considerable support from: Sharon Lutz, Susan Gutenberger and assistants from the USFWS; Don Larsen, Andy Dittman, Charlie Waters and assistants from NOAA Fisheries; Zach Penney, Doug Hatch, and many others at the Columbia River InterTribal Fish Commission; and Kerry Naish and others at the University of Washington. The following individuals are now retired but we acknowledge their many and invaluable contributions over the years: Dave Fast, David Lind, Bill Fiander, and Paul Huffman of the YN, Curt Knudsen from Oncorh Consulting and Doug Neeley from IntSTATS Consulting.

Special acknowledgement and recognition is owed to all of the dedicated Yakama Nation and YKFP personnel working on various tasks including Ray Decoteau, Joe Yallup, Joe Jay Pinkham III (retired), Leroy Senator (retired), Sy Billy, Wayne Smartlowit, Morales Ganuelas, Pharamond Johnson, Steve Salinas, Shiela Decoteau, Jimmy Joe Olney, Conan Northwind, Quincy Wallahee, Andrew Lewis, Nate Pinkham, Gene Sutterlick, Germaine Hart, Jamie Bill, Nate Pinkham, William Manuel, Terrance Compo, Levi Piel, Winna Switzler, Florence Wallahee, Ted Martin and Arnold Barney. The accomplishments and achievements documented here are a direct result of their dedication and desire to seek positive results for the betterment of the resource. Also, these achievements are attainable because of the efficient and
essential administrative support received from all of the office and administrative support personnel for the YKFP including: Rubi Rodriguez, Joey Estrada, Shirley Alvarado, and Adrienne Wilson.

We would especially like to thank former contributors to the Yakima/Klickitat Fisheries Project including Bruce Watson, Joel Hubble, Steve Schroder, Todd Pearsons, Craig Busack, Ray Brunson, Joy Evered, and Bill Hopley. These individuals put in countless hours of hard work during the planning, design, and implementation of this project. Their contributions helped to lay a solid foundation for this project and our monitoring and evaluation efforts. Dan Barrett (retired) served as the manager of the CESRF from 1997-2002. He helped to lay a solid foundation for the critical work done day in and day out at the Cle Elum facility.

This work is funded by the Bonneville Power Administration (BPA) through the Northwest Power and Conservation Council's (NPCC) Fish and Wildlife Program. Michelle O'Malley is BPA's contracting officer and technical representative (COTR) for this project. David Byrnes and Patricia Smith served as COTRs in the past and contributed substantially to the project over the years.

## Executive Summary

The Yakima-Klickitat Fisheries Project (YKFP) is a joint project of the Yakama Nation (lead entity) and the Washington State Department of Fish and Wildlife (WDFW) and is sponsored in large part by the Bonneville Power Administration (BPA) with oversight and guidance from the Northwest Power and Conservation Council (NPCC). It is among the largest and most complex fisheries management projects in the Columbia Basin in terms of data collection and management, physical facilities, habitat enhancement and management, and experimental design and research on fisheries resources. The YKFP is attempting to evaluate all stocks historically present in the Yakima Subbasin and apply a combination of habitat restoration and hatchery supplementation or reintroduction, to restore the Yakima Subbasin ecosystem with sustainable and harvestable populations of salmon, steelhead and other at-risk species. This project and report address regional monitoring and evaluation strategies and sub-strategies as they apply to spring Chinook, summer/fall Chinook, and coho work in the Yakima Subbasin. This project (199506325) is related to numerous other projects in the Yakima Subbasin; additional information is available in the annual reports of these related projects.

The YKFP began a spring Chinook salmon hatchery program at the Cle Elum Supplementation and Research Facility (CESRF) near Cle Elum on the upper Yakima River in 1997. This program is a supplementation effort targeting the upper Yakima River population and is designed to test whether artificial propagation can be used to increase natural production and harvest opportunities while limiting ecological and genetic impacts. It is an integrated hatchery program because only natural-origin brood-stock is used and returning hatchery-origin adults are allowed to spawn in the wild. The program employs "best practice" hatchery management principles including reduced pond densities, strict disease management protocols, random brood-stock selection, and factorial mating to maximize effective population size. Fish are reared at the central facility, but released from three acclimation sites located near the central facility at: Easton approximately 25 km upstream of the central facility, Clark Flat about 25 km downstream of the central facility, and Jack Creek about 12 km upstream from the Teanaway River's confluence with the Yakima River. The CESRF collected its first spring Chinook brood-stock in 1997, released its first fish in 1999, and age-4 adults have been returning since 2001. The first generation of offspring of CESRF and wild fish spawning in the wild returned as adults in 2005. The program uses the adjacent, un-supplemented Naches River population as an environmental and wild control or reference system.

Adult returns of fall Chinook to the Yakima River Basin consist mostly of hatcheryorigin fish returning from releases averaging 1.6 million Upriver Brights annually from
the Prosser Hatchery which have occurred since 1983. Summer-run Chinook were extirpated from the Yakima Basin by 1970. To increase the temporal and spatial distribution of summer/fall run Chinook in the Yakima River Subbasin, the program began releases of Wells Hatchery summer-run Chinook in the Yakima River Basin in 2009. Coho were extirpated from the Yakima Subbasin by the early 1980s. Pursuant to U.S. v. Oregon court-mandated agreements, substantial numbers (annual average $>$ 700,000 ) of hatchery-reared coho salmon were released into the Yakima River since the mid-1980s. Prior to 1996 the primary purpose of releases was harvest augmentation and fish were released in sub-optimal spawning and rearing areas below Wapato Dam. With the inception of the YKFP in 1996, the objective of the coho program became "to determine the feasibility of reestablishing a naturally spawning coho population" and releases were moved upriver to more suitable habitats for natural coho.

Annual abundance of spring Chinook at Prosser Dam has increased from a 1982-2000 average of about 4,000 fish to a 2001-2019 average of about 9,800 fish. These increases can be attributed to returns from the Cle Elum supplementation program beginning in 2001, improved freshwater passage conditions, improved marine survival, and habitat restoration and enhancement work. Annual abundance of summer/fall Chinook at the Yakima River mouth has increased from a 1983-1999 average of about 1,200 fish to a 2000-2019 average of about 6,600 fish. While this increase coincides with improved ocean conditions, some of the increase may also be due to improved passage in the mainstem Columbia River, and improvements in spawning and rearing protocols. Approximately 250 summer-run Chinook were estimated to pass above Prosser Dam in 2019. The 2019/2020 adult passage over Prosser Dam was approximately 2,400 coho. An additional 1,400 adults returned directly into the Prosser Fish Hatchery. The hatchery is located approximately 1 mile below the dam and the returning adults are used for brood stock. Coho returns to Prosser averaged over 5,300 fish from 1997-2019 (an order of magnitude improvement from the average for years prior to the project) including estimated returns of wild/natural coho averaging over 800 fish annually since 2001.

Trends in adult productivity indices for Yakima Basin natural-origin spring Chinook appear to be very similar for both Upper Yakima and Naches populations. Trends in adult productivity indices for natural-origin coho are not as clear. Under present conditions, productivity for spring Chinook appears to peak at about 1,000 to 1,500 spawners and decline as spawner abundance approaches 2,000 fish or greater. These data indicate that density-dependent limiting factors depress natural productivity at fairly low population abundance in the Yakima River Basin. Until these factors are fully addressed, supplementation yields higher overall productivity rates and can be used to return adults to fisheries and to augment natural spawning populations.

For smolt migration years 2000 to present, annual abundance estimates of juvenile smolts migrating downstream at Prosser Dam averaged 212,800 wild/natural spring Chinook, 329,200 CESRF-origin spring Chinook, 44,000 wild/natural-origin coho, and 262,800 hatchery-origin coho. Preliminary smolt-to-adult survival indices averaged approximately $2.6 \%$ and $2.9 \%$ for natural-origin spring Chinook and coho, respectively. Because of many complexities associated with the production of smolt indices, these data are useful for analysis of trends but should not be used as direct citations of, or for comparisons of marked and unmarked, smolt-to-adult survival rates. Substantial juvenile mortality occurs as smolts migrate through the Yakima River system. Strategies have been proposed to address limiting factors and improve survival of emigrating Yakima Basin juveniles. As these strategies are implemented, we expect smolt and smolt-to-adult survival to improve.

Spatial distribution of spring Chinook spawners has increased as a result of acclimation site location, salmon homing fidelity and more fully seeding preferred spawning habitats. Spring Chinook redd counts in the Teanaway River increased from a pre-supplementation average of 3 redds per year to a post-supplementation average of 55 redds per year. Fall Chinook redd distribution in the Yakima River Basin appears to be experiencing a transition with an increasing proportion of redds observed above Prosser Dam in the most recent decade. This change is primarily attributed to substantial changes in lower Yakima River habitats in recent years. Redd counts and spatial distribution of coho have increased substantially in recent years, with about 410 redds enumerated annually on average in tributaries in the upper watersheds since 2004. In 2019/2020, 112 coho redds were observed in tributaries in the Naches and Upper Yakima Subbasins. Approximately, 80 redds were found in the Naches River and over 60 were found in the mainstem Yakima River above Roza Dam.

Monitoring and evaluation of diversity metrics is primarily focused on the CESRF spring Chinook program in the Upper Yakima River. Generally, we have detected small, but significant differences between hatchery- and natural-origin fish in some juvenile and adult traits with many results already published in the peer-reviewed literature.

Overall average fine sediment levels in the Naches and Upper Yakima River subbasins over many years of sampling continue to trend downward.

We believe Yakima Basin spring Chinook contribute minimally to marine fisheries as their spatial and temporal ocean migration patterns do not appear to intersect with marine fisheries. However, Yakima Basin fall- and summer-run Chinook and coho do
contribute substantially to marine fisheries and to mainstem Columbia River fisheries from the mouth to the Hanford Reach area. Recreational spring Chinook fisheries have returned to the Yakima River Basin after a 40-year absence. This has contributed to improved relationships between all the Basin's stakeholders and increased opportunities for collaboration.

Supplementation has increased spring Chinook redd abundance in the Upper Yakima relative to the Naches control system. We observed an average increase in redd counts in the upper Yakima about $57 \%$ greater than that in the Naches system from the pre- to post-supplementation periods. Natural-origin returns of adult spring Chinook in the post-supplementation period (2005-2019) are trending downward relative to the pre-supplementation period (1982-2004) in both the Upper Yakima and Naches Rivers but the trend in the Naches control system is a steeper decline. After several generations of study, the results (many of which are published in the peerreviewed literature) from the spring chinook supplementation program in the Upper Yakima River demonstrate that a well-designed and carefully managed integrated hatchery program using $100 \%$ natural-origin broodstock can produce fish for harvest and return fish to the natural spawning grounds with minimal negative impacts to the target ecosystem. Coho re-introduction research in the published literature suggests that hatchery-origin coho, with a legacy of as many as 10 to 30 generations of hatchery-influence, can reestablish a naturalized population after as few as 3 to 5 generations of outplanting in the wild.

YKFP efforts to monitor and evaluate hatchery reform focus on the CESRF spring Chinook program which was designed explicitly for this purpose from its inception. By designing the program to use only natural-origin fish for brood-stock, the program has demonstrated reduced genetic divergence for the integrated program compared to a traditional segregated hatchery program. The CESRF is also meeting or exceeding scientific recommendations for proportionate natural influence (PNI) on an annual basis with a 19 -year mean annual PNI of $65 \%$. The project is thus far meeting or exceeding most other established objectives related to hatchery reform.

Major piscivorous predators in the Yakima River Basin include: common mergansers, American white pelicans, double-crested cormorants, gulls, great blue herons, northern pike minnows, and smallmouth bass. The project has initiated efforts to control the pike minnow and smallmouth bass populations.

Project results are communicated broadly through the annual science and management conference, technical reports and peer-reviewed journal publications (see references and project-related publications), and via several related web sites described in Appendix A.

## Introduction

The Yakima-Klickitat Fisheries Project (YKFP) is a joint project of the Yakama Nation (lead entity) and the Washington State Department of Fish and Wildlife (WDFW) and is sponsored in large part by the Bonneville Power Administration (BPA) with oversight and guidance from the Northwest Power and Conservation Council (NPCC). It is among the largest and most complex fisheries management projects in the Columbia Basin in terms of experimental design and research on fisheries resources, physical facilities, habitat enhancement and restoration, and data collection and management. Consistent with Wy-Kan-Ush-Mi Wah-Kish-Wit (CRITFC 1995) and using principles of adaptive management (Salafsky et al. 2001), the YKFP is attempting to evaluate all stocks historically present in the Yakima Subbasin and apply a combination of habitat restoration and hatchery supplementation or reintroduction, to restore the Yakima Subbasin ecosystem with sustainable and harvestable populations of salmon, steelhead and other at-risk species.

The original impetus for the YKFP resulted from the landmark fishing disputes of the 1970s, the ensuing legal decisions in United States versus Washington and United States versus Oregon, and the region's realization that lost natural production needed to be mitigated in upriver areas where these losses primarily occurred. The YKFP was first identified in the NPCC's 1982 Fish and Wildlife Program (FWP) and supported in the U.S. v Oregon 1988 Columbia River Fish Management Plan (CRFMP). A draft Master Plan was presented to the NPCC in 1987 and the Preliminary Design Report was presented in 1990. In both circumstances, the NPCC instructed the Yakama Nation, WDFW and BPA to carry out planning functions that addressed uncertainties in regard to the adequacy of hatchery supplementation for meeting production objectives and limiting adverse ecological and genetic impacts. At the same time, the NPCC underscored the importance of using adaptive management principles to manage the direction of the Project. The 1994 FWP reiterated the importance of proceeding with the YKFP because of the added production and learning potential the project would provide. The YKFP is unique in having been designed to rigorously test the efficacy of hatchery supplementation. Given the current depressed status of many salmon and steelhead stocks, and the heavy reliance on artificial propagation as a recovery tool, YKFP monitoring results have great region-wide significance.

Supplementation is envisioned as a means to enhance and sustain the abundance of wild and naturally-spawning populations at levels exceeding the cumulative mortality burden imposed on those populations by habitat degradation and by natural cycles in environmental conditions. A supplementation hatchery is properly operated as an
adjunct to the natural production system in a watershed. By fully integrating the hatchery with a naturally-producing population, high survival rates for the component of the population in the hatchery can raise the average abundance of the total population (hatchery component plus naturally-producing component) to a level that compensates for the high mortalities imposed by human development activities and fully seeds the natural environment. However, it is important to recognize that "rebuilding natural populations will ultimately depend on improving habitat quality and quantity" (ISRP 2011, Venditti et al. 2017) of which habitat connectivity is an essential component (CRITFC 1995, Milbrink et al. 2011). Hatchery programs, even "state of the art" integrated supplementation programs designed to follow all of the best management practice recommendations (Cuenco et al. 1993, Mobrand et al. 2005), do not directly affect any of these habitat parameters which are vital to improving natural productivity. Therefore, the YKFP is working with partners in multiple forums to implement habitat restoration and water resource management projects designed to address factors limiting productivity (see Yakima Subbasin, Recovery, and Integrated plans).

The objectives of the YKFP are to: enhance existing stocks; re-introduce extirpated stocks; protect and restore habitat in the Yakima Subbasin; operate using a scientifically rigorous process that will foster application of the knowledge gained about hatchery supplementation and habitat restoration throughout the Columbia River Basin; and use Ecosystem Diagnosis and Treatment (EDT) and other modeling tools to facilitate planning for project activities. In strictly scientific terms the stated purpose of the project is, "to test the assumption that new artificial production can be used to increase harvest and natural production while maintaining the long-term genetic fitness of the fish population being supplemented and keeping adverse genetic and ecological interactions with non-target species or stocks within acceptable limits" (RASP 1992, BPA 1996). WDFW is addressing some critical uncertainties (see Columbia River Basin Research Plan and Critical Uncertainties for the Columbia River Basin Fish and Wildlife Program) related to genetic and ecological interactions under project 1995-064-25. We are working jointly with WDFW and CRITFC (2009-009-00) to address fish propagation, predation, harvest, and monitoring and evaluation methodology uncertainties including:

Fish Propagation Question 1. Are current propagation efforts successfully meeting harvest and conservation objectives while managing risks to natural populations?
1.2. Can hatchery production programs meet adult production and harvest goals (integrated and segregated) while protecting naturally spawning populations?
1.4. What is the magnitude of any demographic benefit or detriment to the production of natural-origin juveniles and adults from natural spawning of hatchery-origin supplementation adults?
1.5. What are the range, magnitude and rates of change of natural spawning fitness of integrated (supplemented) populations, and how are these related to management rules including the proportion of hatchery fish permitted on the spawning grounds, and the proportion of natural origin adults in the hatchery broodstock?

Predation Question 1. Are the current efforts to address predation and reduce numbers of predators effective?

Predation Question 2. Are there actions other than removing predators that could reduce predation on listed species?

Harvest Question 1. Do current harvest and escapement strategies provide the expected results in supporting recovery efforts and providing harvest opportunities?

Monitoring and evaluation methods Question 1. Are current methods to ... count fish and to measure productivity adequate to cost effectively inform decisions?

Monitoring and evaluation methods Question 2. Are there innovative methods for counting fish and measuring their productivity that would better inform decisions?

YKFP-related project research in the Yakima River Basin has resulted in the publication of over 60 manuscripts in the peer-reviewed literature (see References and Project-Related Publications). The status of ongoing research relative to the above uncertainties is presented as part of this report.

This report includes sections on the following regional research, monitoring, and evaluation (RME) strategies: fish population status, harvest, hatchery, and predation. Each section addresses all relevant sub-strategies that apply to this project. The report addresses these strategies and sub-strategies as they apply to spring Chinook (Oncorbynchus tshanytscha), summer/fall Chinook (O. tshanytscha), and coho (O. kisutch) RM\&E work in the Yakima subbasin. Steelhead (O. mykiss) RME work is addressed in related VSP (2010-030-00), on-reservation watersheds (1996-035-01), and Kelt Reconditioning (CRITFC 2008-458-00 and 2007-401-00) projects. WDFW is addressing hatchery uncertainties related to genetic and ecological interactions under project 1995-064-25. YKFP-related habitat activities for the Yakima Subbasin are addressed under projects 1997-051-00 and 1996-035-01 (except for sediment sampling
which is addressed here). Hatchery Production Implementation ( $O \& M$ ) is addressed under project 1997-013-25. Data and findings presented in this report should be considered preliminary until results are published in the peer-reviewed literature.

Study Area
The project study area is the Yakima River Basin WRIA 37/38/39 (Figure 1).

Figure 1. Yakima River Basin and Yakama Nation/YKFP-related artificial production and monitoring facilities (map provided by Paul Huffman).

## Fish Population Status Monitoring

## Status and Trend of Adult Fish Populations (Abundance)

Methods: Adult salmon populations in the Yakima River Basin are enumerated at Prosser Dam using video equipment installed in all three adult fish ladders (monitoringresources.org methods 143, 144, 307, 418, 515). At both Prosser and Roza Dams, adult fish traps are also used on a seasonal basis for biological sampling and enumeration (monitoringresources.org methods 135). When the Roza adult trap is not in operation, video equipment is also employed at the adult fish ladders there. However, camera placement and actual viewing area are limited; these combined with water clarity issues during certain river conditions all affect video enumeration at Roza Dam. Automatic Passive Integrated Transponder (PIT) tag detectors are also employed at all fish ladders at both dams (see sites RZF and PRO in ptagis.org). For the safety and protection of personnel and equipment, video and PIT-detection equipment are removed during periods of high river flow. In these instances, biologists attempt to extrapolate fish counts using data from before and after the high flow event. Although adult passage over spillways is believed to occur when flows are favorable, Prosser Dam counts are generally considered by Yakama Nation biologists to be within $+/-5 \%$ of actual fish passage. Roza Dam counts during trap operation (generally the entire spring Chinook counting period, March-September) are considered virtually $100 \%$ accurate; however, during the late fall and winter counting period when video equipment is used at least part of the time, accuracy may fall to only $50-75 \%$ of actual fish passage based on preliminary evaluation of PIT tag detection data. Fish are denoted as hatchery- or natural-origin based on presence or absence respectively, of observed external or internal marks or tags (monitoringresources.org method 342). Chinook are denoted as spring-, summer-, or fall-run based on review of PIT-detection data and visual observations of coloration and body morphometry.

At Prosser Dam, time-lapse video recorders (VHS) and a video camera were used at viewing windows at each of the three fishways. Digital video recorders (DVR) and progressive scan cameras (to replace the VHS systems) were tested at each of the three Prosser fishways in 2007 and became fully operational in February of 2008. The new system functions very similarly to the VHS system but provides digital video data readily downloadable to the viewing stations in Toppenish. This new system also allows technicians in Toppenish to scan rapidly to images of fish giving a more timely and accurate fish count. The technicians review the images and record various types of data for each fish that migrates upstream via the ladders. The data are entered into a Microsoft Access database, and daily dam count reports are available at:
http://dashboard.yakamafish-star.net/DataQuery. Similarly at Roza Dam, adult trap data are entered into a Microsoft Access database, and daily dam count reports (with video counts integrated) are available at: http://dashboard.yakamafishstar.net/DataQuery. Post-season, counts are reviewed and adjusted for data gaps and knowledge about adult and jack lengths from sampling activities with corrections made to our master data sets. In addition to adult abundance data, Yakima Basin adult trap sampling (login required) data for the Prosser and Roza data sets are available at: http://dashboard.yakamafish-star.net/DataQuery.

Spring Chinook began returning from the Cle Elum Supplementation and Research Facility (CESRF) in 2000 (jacks) and 2001 (adults). All CESRF-origin spring Chinook are marked. Due to physical and logistical constraints at the Prosser Hatchery it is not possible to mark all hatchery releases of summer/fall run Chinook without jeopardizing fish health and survival but these issues are being addressed through the Master Planning process (Yakama Nation 2019). Thus, enumeration of hatchery- and natural-origin summer/fall run Chinook adult returns is not presently available but will be available in the future. New marking protocols made it possible to distinguish hatchery- and natural-origin coho beginning with return year 2001.

## Results:

Figure 2. Estimated counts of natural- and Cle Elum Supplementation and Research Facility (CESRF-) origin spring Chinook (adults and jacks) at Prosser Dam, 1982-present.

Figure 3. Estimated returns of adult and jack summer- and fall-run Chinook to the Yakima River mouth, 1983-present.

Figure 4. Estimated counts of marked (presumed hatchery-origin) and unmarked (presumed natural-origin) Coho (adults and jacks) at Prosser Dam 1986-present.

Figure 5. Estimated counts of natural- and Cle Elum Supplementation and Research Facility (CESRF-) origin spring Chinook (adults and jacks) at Roza Dam, 1982-present.

Figure 6. Average daily passage of Chinook and Coho (adults and jacks) at Prosser Dam, 2010-2019.

Figure 7. Passage timing of adult and jack Chinook at Prosser Dam in 2019 by run (see Methods).

## Discussion:

Annual abundance of spring Chinook at Prosser Dam has increased from a 1982-2000 average of about 4,000 fish to a 2001-2019 average of about 9,800 fish (Figure 2). Annual abundance of spring Chinook at Roza Dam has increased from a 1982-2000 average of about 2,300 fish to a 2001-2019 average of approximately 6,600 fish (Figure 5). These increases beginning in 2001 coincide with the first adult returns from the Cle Elum supplementation program. However, freshwater passage conditions, marine survival, and habitat restoration and enhancement work also affect survival and return rates. The lower adult returns observed in 2003 and 2007 coincide with notable droughts during the corresponding smolt outmigration years of 2001 and 2005. Returns in 2015, 2018, and to a lesser extent 2017 were affected by thermal barriers in the lower Yakima River during the adult migration timeframe. Discussion of uncertainties relating to the Cle Elum spring Chinook supplementation program is included under Hatchery Monitoring later in this report. Additional data and detail on the Cle Elum spring Chinook supplementation program and the status of natural- and CESRF-origin spring Chinook in the Yakima River Basin are provided in Appendix B.

Although some natural production is occurring, adult returns of fall Chinook to the Yakima River Basin consist mostly of hatchery-origin fish returning from annual releases of Upriver Brights from the Prosser Hatchery which have occurred since 1983 and averaged about 1.9 million since 1999 (Yakama Nation 2019). In addition, the Yakama Nation has a goal of re-establishing Summer-run Chinook which were extirpated from the Yakima Basin by 1970. Pursuant to this goal we began releases of Wells Hatchery summer-run Chinook in the Yakima River Basin in 2009. Annual
abundance of summer/fall Chinook at the Yakima River mouth has increased from a 1983-1999 average of about 1,200 fish to a 2000-2019 average of about 6,600 fish (Figure 3). While this increase coincides with improved ocean conditions, some of the increase may also be due to improved passage in the mainstem Columbia River, and improvements in spawning and rearing protocols. By re-establishing the summerrun component we seek to increase the temporal (Figures 6 and 7) and spatial distribution of summer/fall run Chinook in the Yakima River Subbasin (Yakama Nation 2019). Approximately 250 summer-run Chinook were estimated to pass above Prosser Dam in 2019 (Figure 7).

Coho were extirpated from the Yakima Subbasin by the early 1980s. Pursuant to U.S. v. Oregon court-mandated agreements, substantial numbers (annual average $>700,000$ ) of hatchery-reared coho salmon were released into the Yakima River since the mid1980s. Prior to 1996 the primary purpose of releases was harvest augmentation and fish were released in sub-optimal spawning and rearing areas below Wapato Dam. With the inception of the YKFP in 1996, the objective of the coho program became "to determine the feasibility of reestablishing a naturally spawning coho population" and releases were moved upriver to more suitable habitats for natural coho. Monitoring of these efforts to re-introduce a sustainable, naturally spawning coho population in the Yakima Basin have indicated that coho returns averaged over 5,300 fish from 1997-2019 (an order of magnitude improvement from the average for years prior to the project) including estimated returns of wild/natural coho averaging over 800 fish annually since 2001 (Figure 4).

## Status and Trend of Adult Productivity

## Methods:

We used recruit-per-spawner relationships (Ricker 1975) to describe adult-to-adult productivity indices. Species-specific methods were as follows.

## Spring Cbinook

Estimated natural-origin spawners for the Upper Yakima River were calculated as the estimated escapement above Roza Dam plus the estimated number of spawners between the confluence with the Naches River and Roza Dam. Total natural-origin returns to the Upper Yakima River were developed using run reconstruction techniques (Appendix B). Age composition for Upper Yakima returns was estimated from spawning ground carcass scale samples (monitoring resources.org method 112) for the years 1982-1996 and from Roza Dam brood-stock collection samples (Knudsen et al. 2006; Appendix B) for the years 1997 to present. Since age-3 fish (jacks) are not collected for brood-stock in proportion to the jack run size, the proportion of age-3 fish in the upper Yakima for 1997 to present was estimated using
the proportion of jacks (based on visual observation) counted at Roza Dam relative to the total run size.

Estimated spawners and total returns for Naches River Subbasin natural-origin spring Chinook were calculated using run reconstruction techniques (Appendix B). Age composition for Naches Basin age- 4 and age- 5 returns were estimated from spawning ground carcass scale samples (monitoring resources.org method 112). The proportion of age-3 fish was estimated after reviewing jack count (based on visual observations) data at Prosser and Roza dams.

Estimated spawners at the CESRF were the total number of wild/natural fish collected at Roza Dam and taken to the CESRF for production brood-stock (Knudsen et al. 2006; Appendix B). Total returns of CESRF-origin fish were based on run reconstruction and Roza dam sampling operations. Age composition for CESRF fish was estimated using scales and PIT tag detections from CESRF fish sampled passing upstream through the Roza Dam adult monitoring facility (Knudsen et al. 2006; Appendix B).

## Coho

From central British Columbia south, the vast majority of coho salmon adults are 3-year-olds, having spent approximately 18 months in fresh water and 18 months in salt water (Loeffel and Wendler 1968, Wright 1970). Therefore, we estimated a naturalorigin productivity (recruits per spawner) index by dividing natural-origin returns to Prosser Dam by the estimated returns to Prosser Dam three years prior. We computed this index for both adult and combined adult and jack returns per adult and combined adult and jack spawner. Note that this method will bias productivity estimates high, as it assumes no natural production from hatchery-origin spawners.

## Summer/Fall Run Cbinook.

Adult fall Chinook returning to the Yakima Basin consist of hatchery-origin returns from releases at and above Prosser Dam and natural-origin returns from fish spawning naturally in the Yakima River. Due to fiscal, physical, logistical, and policy considerations, only a small proportion of hatchery-origin releases have been externally marked. Therefore, it is impossible at present to know the origin of unmarked adult fall Chinook counted at Prosser. Additional marking is proposed for hatchery-origin releases as part of the Master Plan (Yakama Nation 2019), which will allow development of a comprehensive brood/cohort age at return table for naturaland hatchery-origin returns. Methods and results for evaluating adult productivity of summer/fall run Chinook will be included in future reports and publications as the data become available.

## Results:

Table 1. Adult-to-adult productivity indices for upper Yakima wild/natural spring Chinook.

Figure 10. Productivity indices for age-3 natural-origin coho, brood years 2001-2016.

## Discussion:

Recruit per spawner data for the Upper Yakima and Naches spring Chinook populations are highly correlated (Tables 1 and 2; Pearson's correlation
coefficient $=0.87$ ) and analysis of variance indicates the means ( $\pm$ one standard error) in the 31 -year data set are not different (Upper Yakima $=1.52 \pm 0.40$; Naches $=1.61 \pm 0.32 ; P=0.85)$. Trends in adult productivity indices for Yakima Basin natural-origin spring Chinook are also very similar for both Upper Yakima (Figure 8) and Naches (Figure 9) populations. Under present conditions, productivity for spring Chinook appears to peak at about 1,000 to 1,500 spawners and declines as spawner abundance approaches 2,000 fish or greater (Figures 8-9). The trend in adult productivity indices for natural-origin coho (Figure 10) is not as obvious, and 2014 marked the first year that we observed high coho spawner escapements (when hatchery-origin spawning escapement is included) similar to those we have observed with spring Chinook in some recent years. These data indicate that density-dependent limiting factors (see YSFWPB 2004) depress natural productivity at fairly low population abundance in the Yakima River Basin, as is the case for most salmon populations throughout the Columbia River Basin (ISAB 2015). Until these factors are fully addressed, supplementation yields higher overall productivity rates and can be used to return adults to fisheries and to augment natural spawning populations (Table 3). While higher spawner abundances under present conditions do not yield increased adult production, these fish still contribute to more fully seeding available habitats, increased spatial and temporal diversity, and nutrient enhancement that should eventually lead to increased natural food supply and higher productivity in the future (NRC 1996, see especially pp. 368-369; Kiffney et al. 2014).

## Status and Trend of Juvenile Abundance

Methods: The Yakama Nation releases a number of hatchery-origin smolts annually pursuant to U.S. v Oregon Management Agreements. Adult returns from these releases serve to mitigate for lost harvest opportunity (due to alteration of the Columbia River ecosystem and associated losses in natural production and productivity), to augment the number of fish spawning naturally (supplementation), or a combination of the two. Juveniles are released from many locations as yearlings or subyearlings depending on the goals of the specific programs. As these juveniles migrate downstream, they are mixed with naturally produced juveniles.

Above Prosser Dam, a portion of the river flow is diverted into the Chandler canal to generate electrical power and serve irrigation districts downstream. Juvenile fish are diverted into the Canal (and subsequently the Chandler juvenile monitoring facilityCJMF, Figure 1) at different rates depending on river and canal flow. Smolt sampling efforts at the CJMF near Prosser Dam were conducted annually from early winter through early summer corresponding with salmon smolt out-migrations. A portion of entrained salmon outmigrants (regulated by a timed gate) was manually counted and sampled for biological data on a daily basis and all PIT tagged fish were interrogated.

Sampling methods were described in Busack et al. (1997) and were consistent with monitoringresources.org methods 1562, 1563, 1595, and 1614.

Paired releases of PIT-tagged smolts were made in order to estimate the fish entrainment and canal survival rates in relation to river conditions and canal operations. For outmigration years 1999 through 2014, these data were used to generate a multi-variate river flow/canal entrainment relationship (D. Neeley 2010 and 2012a). Over a range of flow diversion rates, juvenile fish entrainment rates generally fit a logistic curve: at low diversion rates, the entrainment rate is lower than the diversion rate, and at high diversion rates the entrainment rate is higher than the diversion rate. In recent years it became difficult to adapt the model to higher winter and spring flows and to river channel changes, partly because at low diversion rates it was difficult to capture enough fish to get many point estimates of entrainment rate. The releases that were made, however, still tended to support a low entrainment rate relative to diversion rate at high river flows. For some years, Prosser smolt passage estimates produced by this model were outside of what were considered reasonable bounds (e.g., entrainment-based Prosser passage estimates approached or even exceeded known releases for hatchery-origin spring Chinook far upstream). This required us to reevaluate and change our methodology. The proportions of all PITtagged smolts released above Prosser and detected at mid-Columbia dams that were previously detected in the Chandler Canal bypass now serve as estimates of bypassdetection efficiency. Expanded Prosser passage estimates were then derived using the juvenile sample counts and detection efficiencies as described in Appendix C. These methods were generally consistent with monitoringresources.org methods 435, 623 and 1743.

## Results and Discussion:

At the CESRF, the number of release groups and total number of spring Chinook released diverged from the facility goal of 810,000 smolts in some years. In brood year 1997, the Jack Creek acclimation facility was not yet complete and project policy and technical teams purposely decided to under-collect brood stock to allow a methodical testing of the new facility's operations with less risk to live fish, which resulted in the stocking of only 10 of the 18 raceways. In brood year 1998, the project did not meet facility release goals due to a biological specification that no more than $50 \%$ of returning wild fish be taken for brood stock. As a result, only 16 raceways were stocked with progeny of the 1998 brood. In the same year, raceway 4 at the Jack Creek acclimation site suffered mechanical failures causing loss of flow and reduced oxygen levels and resulted in the loss of approximately one-half the fish in this raceway prior to release. In the drought year of 2001, a large number of returning adults presented with high enzyme-linked immunosorbent assay (ELISA) levels of Renibacterium salmoninarum, the causative agent of bacterial kidney disease (BKD). The
progeny of these females were purposely destroyed. As a result, only nine raceways were stocked with fish. The project decided to use the fish from an odd raceway for a predator avoidance training sub-experiment (these fish were subsequently acclimated and released from the Easton acclimation site).

1. Brood years 1997-2001: Optimum Conventional Treatment (OCT). Brood Years 2002-2004: Normal (High) growth. Brood Years 2005-2012: Normal feed at Cle Elum or accl. sites.
2. Brood years 1997-2001: Semi-natural Treatment (SNT). Brood Years 2002-2004: Slowed (Low) growth. Brood Year 2005, 2007-2012: saltwater transition feed at accl. Sites; 2014: BioPro vs BioVIT. Brood Year 2006: EWS diet at CESRF through May 3, 2007.
3. $\mathrm{CFJ}=$ Clark Flat; ESJ=Easton; JCJ=Jack Creek.
4. At the Jack Creek acclimation site only 4 of 6 raceways were stocked, and raceway 4 suffered mechanical failures resulting in the loss of about 20,000 OCT (control) fish.
5. High BKD incidence in adult broodstock reduced production to just 9 ponds (Clark Flat 1-2, Jack Creek, and Easton). Easton ponds were used for predator avoidance trained (PAT) fish and a single Cle Elum pond was spread between 6 ponds at Easton with crowders used to simulate pond densities for fish at other acclimation sites. These releases were excluded from mean pond density calculations by treatment.
6. At the Jack Creek acclimation site raceway 3 suffered mechanical failures resulting in the loss of about 45,000 high-growth (control) fish.

1. All fish released as subyearlings unless otherwise noted.

For smolt migration years 2000 to present, annual abundance estimates of juvenile smolts migrating downstream at Prosser Dam averaged 219,400 wild/natural spring Chinook, 329,700 CESRF-origin spring Chinook, 44,000 wild/natural-origin coho, and 262,800 hatchery-origin coho (Table 9). These are the years for which our data and methods are considered most reliable. Juvenile passage estimates for earlier years
are provided below under "Status and Trend of Juvenile Productivity"; however, the reader should be aware that we have less confidence in these data because we have refined data collection protocols and passage estimation methods over time. As the majority of fall Chinook smolt migrants are unmarked hatchery-origin fish, we provide only the gross abundance indices below under "Status and Trend of Juvenile Productivity". The reader is cautioned to pay particular attention to the factors complicating estimates of juvenile abundance and productivity described under "Status and Trend of Juvenile Productivity".

Table 9. Estimated smolt passage at Prosser Dam for Yakima Basin wild/natural and hatchery-origin spring Chinook and coho.

## Status and Trend of Juvenile Migration Survival to McNary Dam

Methods: For all species, releases of PIT tagged smolts provided a means to estimate smolt survival to McNary Dam. For most releases, PIT-tag detectors were located in or near the exit(s) from the release sites (monitoringresources.org 1558) and allowed estimation of the number of PIT-tagged fish leaving the release sites. To estimate the survival of smolts detected leaving the release sites that eventually pass McNary Dam, the proportion of PIT-tagged smolts detected leaving the release sites that were later detected at McNary Dam was divided by McNary Dam's detection efficiency. The estimated detection efficiency was the number of smolts detected passing dams
downstream of McNary that were previously detected passing McNary divided by the total number of smolts passing the downstream dams, whether or not the smolts were previously detected at McNary. Our methods are described in detail in Appendix C and are generally consistent with Sandford and Smith (2002) and with monitoringresources.org methods 623 and 1536. We used weighted logistic or weighted least squares analysis of variance to analyze differences in survival metrics and indices between various release sites, years and treatments. Additional detail, results and discussion are provided in Appendices D (spring Chinook), E (coho), and F (summer-run Chinook). There were no PIT-tagged releases of fall-run Chinook in 2019; the latest results for this species were presented in Appendix G of Fiander et al. (2019).

## Results and Discussion:

For spring Chinook, we compared survivals to McNary Dam of CESRF hatchery-and natural-origin PIT-tagged smolts released into the Roza Dam bypass and migrating downstream of Roza Dam contemporaneously on or after March 16. This date was selected because CESRF fish were not allowed to begin volitional emigration from the acclimation sites until March 15. Approximately $81 \%$ of natural-origin spring Chinook smolts PIT-tagged and released at Roza since 1999 migrated downstream of Roza Dam prior to March 16 (derived using queries of PTAGIS database 7/12/2013). Natural and hatchery-origin smolts contemporaneously migrating past Roza from March 16 on are referred to as "late" migrants.

Survival from Roza Dam to McNary Dam was better for late-migrating natural-origin relative to hatchery-origin spring Chinook smolts and for late-migrating relative to early-migrating natural-origin smolts (Figure 11; Appendix D). The pooled mean survival estimate for migration years 1999-2019 was significantly higher for the natural-origin smolts (Figure 11A).

For coho, we estimated survival from acclimation site release to McNary Dam based on life stage, brood source, location, and timing of the releases (Appendix E). The average survival probability of Coho Salmon smolts from the release sites to McNary Dam in 2019 was $14.27 \pm 2.64 \%$, which was lower than both the 2017 estimate ( $29.06 \pm 3.4 \%$ ) and 2018 estimate ( $24.51 \pm 3.2 \%$ ), but higher than the 2015 estimate $(10.12 \pm 1.14 \%)$. Fish released at the Prosser site had higher ( $25.19 \% \pm 2.85 \%$ ) survival compared to releases at all other locations. The survival rate was higher for the Yakima-stock releases ( $17.51 \pm 0.8 \%$ ), followed by Eagle Creek- stock release ( $15.04 \pm 2.4 \%$ ) and Washougal-stock release ( $8.49 \pm 1.6 \%$ ). For the parr-release group, the survival rate of the group was less than the survival rate of the smolt-release group, however the inter-annual variation of the survival rates among these years was similar to that for smolt-releases.

Figure 11. Box plot showing the 20-year average survival probabilities of natural-origin (Natural) and hatchery-origin (Hatchery) spring Chinook Salmon smolt (S. Pandit, Appendix D). A. is the comparison of Late hatchery- and natural-origin smolt; and B. is the comparison between Early- and Late-migrating natural-origin Smolt.

Juvenile survival rates to McNary Dam for summer-run Chinook varied by year over migration years from 2010 through 2019 (Figure 12). The highest average annual survival rate was in $2011(40.15 \% \pm 1.94 \%)$ and the lowest was in 2015 $(0.73 \% \pm 0.47 \%)$. For 2019, the average survival rate from the combined release locations to McNary Dam was $7.22 \% \pm 1.35 \%$, which was higher than 2018's overall survival rate $(2.58 \% \pm 0.41 \%)$. The relationship between the average of May and June river flow measured below Prosser Dam and the annual survival rate (release location to McNary Dam from 2009 through 2019) was strong and statistically significant ( $\mathrm{r}^{2}=0.45, \mathrm{p}=0.03$ ) indicating that survival rate was a function of river flow in May and June. Higher flow in these months results in higher survival of juvenile Summer Chinook outmigrants. We also found that the relationship of size to survival rate from Prosser to McNary dams was similar for April and May releases, but that releases in June depressed the Prosser-to-McNary survival rate over the entire range of fish sizes. A complete report of our study of juvenile outmigration survival of Yakima Basin Summer Chinook to Prosser and McNary dams is provided in Appendix F.

Figure 12. Average annual survival rate (release to McNary Dam) of juvenile Summer Chinook smolts migrating from 2010 through 2019 (S. Pandit, Appendix F).

The data indicate that there are substantial sources of juvenile mortality limiting survival of smolts migrating from release sites in the Yakima River basin. The YKFP is working with partners in multiple forums to implement habitat restoration and water resource management projects that address factors limiting survival and productivity (see Yakima Subbasin, Recovery, and Integrated plans).

## Status and Trend of Juvenile Productivity (smolt-to-adult returns)

## Methods:

Smolt abundance passage estimates at Prosser and the methods used to derive them were described above. For spring Chinook, adult return estimates to the Yakima River mouth were derived using Prosser and Roza adult abundance and harvest data (described in other sections of this report and in Appendix B) and run reconstruction techniques (Appendix B). For coho, we used Prosser adult abundance.

Adult fall Chinook returning to the Yakima Basin consist of hatchery-origin returns from releases at and above Prosser Dam and natural-origin returns from fish spawning naturally in the Yakima River. Due to fiscal, physical, logistical, and policy considerations, only a small proportion of hatchery-origin releases have been externally marked. Therefore, it is impossible at present to know the origin of unmarked adult fall Chinook counted at Prosser. Additional marking is proposed for hatchery-origin releases as part of the Master Plan (Yakama Nation 2019). To derive rough smolt-to-adult return indices for fall Chinook, aggregate (marked and unmarked
combined) smolt passage estimates for the age-3, -4 , and -5 components for a given return year were averaged and the aggregate adult passage estimate for that return year was divided by this average smolt passage estimate. For example, the "Prosser Average Smolts" for adult return year 1988 is the average of marked and unmarked Prosser smolt estimates for juvenile migration years 1983-1985.

We also queried the PTAGIS database for PIT-tagged summer- and fall-run Chinook and Coho that were released in the Yakima Subbasin in recent years and produced McNary Dam juvenile (smolt) to Bonneville Dam adult SAR indices using juvenile detections at or downstream of McNary and adult detections at or upstream of Bonneville Dams.

## Results:

Table 10. Estimated smolt passage at Chandler and smolt-to-adult return indices (Chandler smolt to Yakima R. mouth adult) for Yakima Basin wild/natural and CESRF-origin spring Chinook.

1. Mean flow (cfs) approaching Prosser Dam March 29-July 4 of juvenile migration year. No data available for migration year 1991. In high flow years (flows at or > 5000 cfs ) operation of the Chandler smolt sampling facility may be precluded during portions of the outmigration. Data courtesy of U.S. BOR hydromet.
2. Aggregate of Upper Yakima, Naches, and American wild/natural populations.
3. Estimated smolt-to-smolt (release from upper Yakima River acclimation sites to Chandler) survival for CESRF juveniles.
4. Includes combined age- 3 through age-5 returns. CESRF adult returns and smolt-to-adult survival values are understated relative to wild/natural values since these figures are not adjusted for differential harvest rates in mark selective fisheries in marine and lower Columbia River fisheries.
5. Available data were not sufficient to estimate juvenile flow-entrainment and passage of wild/natural fish.
6. Data for most recent year are preliminary; return data do not include age-5 adult fish.

Table 11. Average combined hatchery- and natural-origin smolt counts at Prosser for fish returning at age-3, -4 , and -5, combined adult returns to Prosser Dam of all age classes, and estimated Prosser smolt-to-adult return indices for Yakima River fall-run Chinook for adult return years 1988-2019.

${ }^{\text {a }}$ PIT-tagged fish released as parr in brood year 2003, 2004 (Upp. Yak.), and 2013 (Naches) experienced very poor $(<1 \%)$ survival to McNary Dam as juvenile smolts and were omitted from this analysis.

## Discussion:

Calculation of smolt-to-adult survival rate indices for Yakima Basin anadromous salmonids are complicated by the following factors:

1) Smolt accounting at Prosser is based on statistical expansion of Chandler smolt trap sampling data using available PIT-detection and flow data and estimated Chandler entrainment rates. Chandler smolt passage estimates are prepared primarily for the purpose of comparing relative marked versus unmarked passage estimates and not for making survival comparisons. While these Chandler smolt passage estimates represent the best available data, there may be a high degree of error associated with
these estimates due to inherent complexities, assumptions, and uncertainties in the statistical expansion process. Therefore, these estimates are subject to revision.
2) Large numbers of Yakima Basin salmonid releases (all CESRF spring Chinook) are adipose-fin clipped and subjected to higher harvest rates than unmarked wild/natural fish in marine and Columbia River mark-selective fisheries. No adjustments have yet been made in the above SAR estimates to account for differential harvest rates in these mark-selective fisheries.
3) Due to issues such as water diversion permitting, size required for tagging, and allowing sufficient time for acclimation, release time for many hatchery-origin juveniles (including all CESRF spring Chinook) may be delayed relative to their wild counterparts. For example, spring Chinook from the CESRF are not allowed to volitionally migrate until at least March 15 of their smolt outmigration year; however, juvenile sampling observations at Roza Dam indicate that a substantial number of wild/natural juveniles migrate downstream during the summer, fall, and winter months prior to their smolt outmigration year. Analysis of juvenile migrant PIT detections at Roza Dam (PTAGIS queries run 7/12/2013) indicated that approximately $81 \%$ of natural-origin spring Chinook migrated downstream of Roza in the fall or winter as juveniles (before CESRF fish would have the opportunity). Comparison of SAR data for non-contemporaneously migrating juveniles may be invalid.

Given these complicating factors, Tables 10-14 present available smolt-to-adult survival indices for Yakima River spring and summer/fall Chinook and coho. Because of the complexities noted above, these data are useful for analysis of trends but should not be used as direct citations of, or for comparisons of marked and unmarked, smolt-to-adult survival rates. The reader is encouraged to contact Yakama Nation technical staff to discuss these and other issues prior to any use of these data or any other estimation of Yakima Basin SARs that may be available through data obtained from public web sites such as RMPC, PTAGIS, DART, FPC or others.

Substantial juvenile mortality of subyearling releases of summer- and fall-run Chinook occurs in the Yakima River between their release sites and McNary Dam (Neeley 2012b). Strategies have been proposed to address limiting factors (YSFWPB 2004) and improve survival of these releases (Yakama Nation 2019). As these strategies are implemented, we expect SARs for summer- and fall-run Chinook to improve substantially from the estimates provided in Table 11 (Yakama Nation 2019). Additional discussion and results for Yakima Basin spring Chinook SARs are presented in Appendix B.

## Status and Trend of Spatial Distribution (Redd Counts)

Methods: Regular foot and/or boat surveys (monitoringresources.org methods 30, $131,285,1508$ ) were conducted within the established geographic range for each species (this is increasing for coho as acclimation sites are located upriver and as the run increases in size). Redds were individually marked during each survey and carcasses were sampled to collect egg retention, scale sample, sex, and body length information and to check for possible experimental marks. River conditions vary from year to year and preclude complete accounting, especially for fall Chinook and Coho. Other agencies (WDFW, Pacific Northwest National Laboratory, and private contractors) have also conducted foot, boat, or aerial surveys for fall Chinook redds in the Yakima River Basin and we have attempted to incorporate available information from those surveys here.

## Discussion:

Spatial distribution of spring Chinook spawners has increased as a result of acclimation site location, salmon homing fidelity and more fully seeding preferred spawning habitats (Dittman et al. 2010). Redd surveys in the Teanaway River conducted annually by Yakama Nation staff since 1981 demonstrate the benefits of reintroducing salmonids into underutilized habitat (Figure 14). The Jack Creek acclimation site began releasing CESRF spring chinook in 2000, with the first age-4 females returning from these releases in 2002. Redd counts in this tributary have increased from a pre-supplementation average of 3 redds per year to a post supplementation average of 55 redds per year. The proportion of natural-origin carcasses increased from less than one percent in 2002 (when CESRF fish first returned to the natural spawning grounds) to $42 \%$ in 2006 when the progeny of the 110 redds produced in 2002 (virtually $100 \%$ of which were produced by CESRForigin fish) returned. These data clearly indicate that naturally-spawning CESRF spring Chinook were successful in returning natural-origin adults back to the Teanaway River. However, redd counts in the Teanaway River remain at or below pre-supplementation levels in some years, including 2018, indicating that habitat factors (primarily low late-summer and fall season flows) continue to deter returning fish and these fish are likely spawning in nearby mainstem and tributary reaches more conducive to survival of progeny (Fast et al. 2015).

Fall Chinook redd distribution in the Yakima River Basin appears to be experiencing a major transition in recent years. Historical redd survey data indicates that a substantial number of fall Chinook spawned below Prosser Dam in the lower Yakima River. However, from 2003-present, an average of approximately 80 percent (range 62 to 90 percent) of surveyed fall Chinook redds have been located above Prosser Dam (Figure 16). Biologists and habitat experts in the subbasin at least partially attribute this change in spawning distribution to the invasion of water stargrass (see Wise et al. 2009) in the lower 43 miles of the Yakima River. With the reintroduction of summer run Chinook, the Yakama Nation is expanding the distribution of summer/fall run Chinook spawners and redds into the middle reaches of the Yakima Basin between the town of Wapato upstream to the confluence with the Tieton River in the Naches subbasin and to Roza Dam in the Upper Yakima subbasin (Figures 1 and 15; Yakama Nation 2012). Summer-run Chinook have now spawned naturally in these habitats since 2013 after an absence of over 40 years.

Coho redd counts and spawner distribution have increased substantially since reintroduction efforts began (Table 16 and Figure 17). Many redds in the mainstem were located intermixed with fall chinook redds, tucked under cut banks or were found in side channels. Tributary redd enumeration and identification continues to be accurate due to the fall low water levels, improving interagency cooperation, and
relatively good weather. One of the overall goals during the present implementation phase (Phase II) of the coho program is to evaluate the transition of redds from the mainstem river into historic tributaries. With the beginning of Phase II of the Coho Program we observed large increases in tributary spawning, with an annual average exceeding 200 redds counted in tributaries since 2004 (Table 16). Although, there were large numbers of potential spawners in $2014(\sim 9,000$ females), river conditions were very unfavorable for finding redds. Winter anchor ice in early December kept surveys to a minimum. This was followed by winter freshets that reduced visibility in the Naches River to the point where visibility was near zero. However, the stability of low water conditions in 2015 might have contributed to good survival of coho eggs from the 2014-2015 spawning season. The 2019 redd count was again below the recent average at 112 (Table 16). However, Coho continue to volunteer into many tributaries, and the fidelity of adults from summer parr plants has shown good results.

Adult Coho plants have also been used to evaluate the feasibility of increasing fish abundance in several tributaries. To determine the spawning success and effects on resident trout of these adult outplants, an intensive monitoring program was conducted in Taneum Creek for brood/spawn years 2007-2014. The results of this evaluation indicate that Coho spawned successfully and have the potential to produce large numbers of returning adult offspring per smolt that survive to McNary Dam as juveniles (Table 17). The total biomass of all salmonids in the stream increased and there were no discernable impacts to resident trout (Temple et al. 2012, 2017).

## Status and Trend of Diversity Metrics

## Methods:

Diversity metrics collected for the Cle Elum Supplementation and Research Facility spring Chinook program in the Upper Yakima River include parameters relating to: eggs (e.g., egg size, KD at emergence, emergence timing, etc.), juveniles (growth and survival, migration timing, fish health, etc.), and adults (size at age, sex composition, migration timing, etc.). Methods for monitoring the spring Chinook program were documented in: the YKFP Monitoring Plan (Busack et al. 1997), the project's "Supplementation Monitoring Plan" (Chapter 7 in 2005 annual report on project genetic studies), and numerous manuscripts in the published literature (see Results and References).

Diversity metrics for returning adult summer/fall Chinook and coho collected at the Prosser Dam denil fish trap include sex ratios, lengths, and weights (monitoringresources.org methods $454,1454,1548,1549,1551,4008,4041$ ). We also queried the PTAGIS database for PIT-tagged summer- and fall-run Chinook that were released in the Yakima Subbasin in recent years and used PIT-detection data at Bonneville Dam for upstream migrants to estimate age composition and run timing of returning fish.

## Results and Discussion:

A detailed presentation of current results for the spring Chinook monitoring program (YN-collected data) are included in Appendix B of this report and are discussed in greater detail in the annual report(s) for WDFW-companion project 1995-064-25. Generally, we have detected small, but significant differences between hatchery- and natural-origin fish in some juvenile and adult traits. Results in the published literature include: Busack et al. (2007), Knudsen et al. $(2006,2008)$, Larsen et al. $(2004,2006$, 2010, 2013), and Pearsons et al. (2009).

Sex ratios, lengths, and weight data for fall Chinook and coho salmon sampled at the Prosser denil adult sampling facility from 2001-present are presented in Tables 18-21. Age composition of summer- and fall-run Chinook are presented in Table 22 and run timing in Figure 18. In addition, preliminary results of some diversity metrics relating to the effort to reestablish a natural spawning coho population in the Yakima Basin were published in Bosch et al. (2007). That study observed divergence in some diversity traits between hatchery- and natural-origin fish suggesting that some renaturalization can be detected in just a few generations after outplanting of hatcheryorigin fish in the wild.

${ }^{1} 10$ of $154(6.5 \%)$ of detections occurred about 90 days post-release in adult ladders at Bonneville Dam and were assumed to be age- 1 returns. However, only 2 of these 10 were confirmed as upstream detections based on later detections at dams upstream of Bonneville. The other 8 detections at Bonneville could have been late-migrating juveniles.

Figure 18. Adult return timing at Prosser Dam of PIT-tagged summer- and fall-run Chinook reared at the Marion Drain and Prosser Hatcheries and released as subyearlings, pooled for return years 2009-2018.

## Habitat Monitoring

While the majority of YKFP habitat activities in the Yakima Basin are addressed in a separate project (1997-051-00), we are monitoring stream sediment loads associated with the operation of dams and other anthropogenic factors (e.g. logging, agriculture and road building) under this contract as sediment loads can affect survival of salmonids (see description and references here).

## Status and Trend of Fine Sediment

Methods: Representative gravel samples (McNiel core samples, monitoring resources 1504) were collected from various reaches in the Little Naches and Upper Yakima Rivers in the fall of 2019. Each sample was analyzed to estimate the percentage of fine or small particles present $(<0.85 \mathrm{~mm})$. The Washington State Timber, Fish, and Wildlife program established guidelines that specify the impacts that estimated sedimentation levels can have on salmonid egg-to-smolt survival. These impact guidelines will inform future analyses of "extrinsic" factors on natural production in the Yakima Basin.

## Results and Discussion:

## Little Naches

A total of 106 McNiel core samples were collected and processed from 9 spawning reaches in the Little Naches drainage this past year. Pyramid Creek has not been sampled since 2009 when the main road going into this reach was decommissioned. Other means to access this sampling site is needed. With this year's monitoring work, the data set for the Little Naches drainage now covers a time period of 35 years for the two historical reaches, and 28 years for the expanded sampling area that includes several tributary streams.

The average percent fine sediment less than 0.85 mm for the entire Little Naches drainage in 2019 was $10.3 \%$ which, although higher than the low observed in 2015, is still below the watershed average observed every year from 1992-2008 (Figure 19). The overall trend remains downward and similar trends can be seen when looking at individual reach conditions over the longer term monitoring period since 1992.

The overall average fine sediment found in spawning substrate remains relatively low and should lessen mortality on incubating eggs and alevins. The reduced rate of fine sediment found can be partially attributed to less anthropogenic disturbance occurring in the watershed in recent years, other than recreational activity. Timber harvest activity and road building has been minimal for several years.

Landowners have also improved roads and trails to reduce sediment delivery. Further, enhanced stream protection measures have been instituted through the Northwest Forest Plan and the Central Cascades Habitat Conservation Plan for over 20 years. These factors have likely helped reduce fine sediment inputs to the stream system. However recreational activity, such as dispersed camping sites and off-road vehicle use near streams, continues to be a concern. Sediment delivery, bank erosion, and loss of riparian vegetation from recreational use have been observed in some localized areas.

Figure 19. Overall Fine Sediment ( $<0.85 \mathrm{~mm}$ ) Trends with $95 \%$ confidence bounds in the Little Naches River Drainage, 1992-2019.

## South Fork Tieton

One reach on the South Fork Tieton River (in the vicinity of Minnie Meadows) has been sampled in the past by the U.S. Forest Service. To the best of our knowledge this reach has not been sampled since 2015. This stream reach typically receives significant bull trout spawning activity and the monitoring efforts provide valuable information on their spawning conditions. Average fine sediment in this reach was $8.9 \%$ in 2015, matching the previous low observed in 1999, and is well below the mean for sediment levels for the 17 years that were sampled (Figure 20).

## Upper Yakima

A total of 60 samples were collected and processed from the Upper Yakima River drainage this past year ( 5 reaches, 12 samples from each reach). The same reaches (Stampede Pass, Easton, Camelot to Ensign Ranch, Elk Meadows, and Cle Elum) have been sampled annually for the past 23 years. The 23 -year trend in average percent fine sediment less than 0.85 mm for the combined Upper Yakima drainage remains downward, although observed fine sediments the past three years have been at or above the average observed since 2009 (Figure 21).

Figure 20. Fine Sediment Trends in the South Fork Tieton River, 1999-2015. Note: Data for 2007 were collected from only 1 Riffle. Data courtesy of U.S. Forest Service.

Figure 21. Overall average percent fine sediment ( $<0.85 \mathrm{~mm}$ ) in spawning gravels of the Upper Yakima River, 1997-2019.

## Summary

We continue to observe a general decreasing trend in average fine sediment levels in the Little Naches and Upper Yakima drainages. Increases observed since 2015 in both drainages could mean that we are experiencing some effect from the large fires in recent years. Overall, the generally low rates of fine sediment should be conducive for egg and alevin survival and should favor salmonid spawning success.

The results of the USFS sampling in the South Fork Tieton River have also been low over a 17 -year sampling period. These conditions should be favorable for early life history survival of bull trout.

Detailed field data including additional tables and graphs for samples collected in the upper Yakima and Naches basins can be obtained from Jim Matthews, fisheries biologist for the Yakama Nation (matj@yakamafish-nsn.gov).

## Harvest Monitoring

## Marine and Mainstem Columbia Fisheries

Methods: We evaluated recoveries of coded-wire tags (CWTs) and PIT tags in out-of-basin fisheries using queries of regional mark information system (RMIS) and PIT Tag Information System (PTAGIS) databases. We coordinated with agencies responsible for harvest management (WDFW, ODFW, USFWS, CRITFC, etc.) to estimate the harvest of target stocks. We reviewed reports produced annually by the Pacific Fisheries Management Council (marine) and the U.S.v Oregon Technical Advisory Committee (mainstem Columbia) to evaluate estimated harvest or
exploitation rates on comparable stocks in these fisheries.

For spring Chinook, additional information was employed that is not readily available for fall Chinook and coho. Standard run reconstruction techniques (Appendix B) were employed to derive estimates of harvest from the Columbia River mouth to the Yakima River mouth for spring Chinook. Data from databases maintained by the U.S. $v$ Oregon Technical Advisory Committee were used to obtain harvest rate estimates downstream of the Yakima River for the aggregate Yakima River spring Chinook population and to estimate passage losses from Bonneville through McNary reservoirs. These data, combined with the Prosser Dam counts and estimated harvest below Prosser, were used to derive a Columbia River mouth run size estimate and Columbia River mainstem harvest estimate for Yakima spring Chinook.

## Results:

Table 23. Marine and freshwater recoveries of CWTs from brood year 1997-2014 releases of spring Chinook from the CESRF as reported to the Regional Mark Information System (RMIS) 04 Dec 2019.

1. Preliminary.

Figure 22. Distribution of coded-wire tag recoveries of Yakima Basin summer/fall run Chinook releases in marine, mainstem Columbia River, and Yakima Basin fisheries. Data retrieved from the regional mark information system (RMIS) for brood year 1997-2007 recoveries.

Recovery data for Yakima River-origin coho are presently limited because few fish have been coded wire-tagged until recent years. We will continue to collect and analyze CWT-recovery data from regional databases and will report this information in the future. 'All H Analyzer' (AHA) modeling for Master Planning purposes assumed that natural- and hatchery-origin Yakima River coho have an exploitation rate of approximately 40 and 60 percent, respectively (Yakama Nation 2019). These estimates include coho caught in marine, Columbia River and Yakima River fisheries.

## Discussion:

Based on available CWT information, harvest managers have long assumed that Columbia River spring Chinook are not harvested in any abundance in marine fisheries as their ocean migration does not generally overlap either spatially or temporally with the occurrence of marine fisheries (TAC 1997). Harvest recoveries of CESRF spring Chinook as reported to RMIS to date appear to confirm this, as marine harvest apparently accounts for only about $0-3 \%$ of the total harvest of Yakima Basin spring Chinook (Table 23). Adult returns of spring Chinook from the CESRF appear to be making substantial contributions to Columbia Basin fisheries (Table 24).

Yakima Basin summer/fall Chinook are harvested in marine fisheries from Alaska to southern Oregon, and in Columbia River fisheries from the mouth to the Hanford Reach (Figure 22). Approximately $71 \%$ of harvest recoveries from Yakima Basin fall Chinook releases for brood years 1997-2007 occurred in marine (44\%) and mainstem Columbia ( $27 \%$ ) fisheries. Out-of-basin harvest rates have not been estimated
specifically for Yakima Basin summer/fall run Chinook, but the 1982-89 brood year average ocean fisheries exploitation rate for mid-Columbia River summer/fall Chinook was $39 \%$, with a total exploitation rate of $68 \%$ estimated for the same years (PSC 1994). Chapman et al. (1994) estimated that the 1975-87 brood year mean exploitation rate for fall Chinook released from Priest Rapids Hatchery was $64 \%$. Harvest rates of these stocks in U.S. fisheries since the mid-1990s have been reduced due to Endangered Species Act (ESA) management concerns as these stocks are intermixed with ESA-listed Snake River fall Chinook populations (NMFS 1999a-d and 2000a-c). It is assumed that Yakima River summer/fall run Chinook are harvested at the same rate in these fisheries as other mid-Columbia River summer/fall Chinook stocks.

## Yakima Subbasin Fisheries

Methods: The two co-managers, Yakama Nation and WDFW, are responsible for monitoring their respective fisheries in the Yakima River. Each agency employs fish monitors dedicated to creel surveys and/or fisher interviews at the most utilized fishing locations and/or boat ramps. From these surveys, standard techniques are employed to expand fishery sample data for total effort and open areas and times to derive total harvest estimates. Fish are interrogated for various marks. Methods are consistent with monitoringresources.org methods 404 and 960.

## Results:

## Discussion:

Adult returns of spring Chinook from the CESRF have substantially increased fishing opportunity for all fishers in the Yakima Basin (Table 25) and returned recreational fisheries to the Basin after a 40 -year absence. This has contributed to improved relationships between all the Basin's stakeholders and increased opportunities for collaboration.

Recreational fishers enjoy a successful annual fall Chinook fishery situated primarily near the mouth of the Yakima River (Table 26). Tribal fishers harvest a substantial, but unquantified number of Yakima Basin-destined fall Chinook (Figure 22) and coho in commercial gillnet fisheries in the Zone 6 fishing area. Because of the quantity and relatively higher quality of fall Chinook and coho available to tribal fishers in Zone 6 Columbia and Klickitat River fisheries, Yakima River tribal harvest is typically at or near zero even though regulations allowing fall season fisheries in the Yakima River are propagated annually by the Yakama Nation.

## Hatchery Research

## Effect of Artificial Production on the Viability of Natural Fish Populations

WDFW is addressing some critical uncertainties (see Columbia River Basin Research Plan and Critical Uncertainties for the Columbia River Basin Fish and Wildlife Program) related to genetic and ecological interactions under project 1995-064-25. We are working jointly with WDFW to address the following additional fish propagation uncertainties:
1.2. Can hatchery production programs meet adult production and harvest goals (integrated and segregated) while protecting naturally spawning populations?
1.4. What is the magnitude of any demographic benefit or detriment to the production of natural-origin juveniles and adults from natural spawning of hatchery-origin supplementation adults?
1.5. What are the range, magnitude and rates of change of natural spawning fitness of integrated (supplemented) populations, and how are these related to management rules including the proportion of hatchery fish permitted on the spawning grounds, and the proportion of natural origin adults in the hatchery broodstock?

## Methods:

The YKFP began a spring Chinook salmon hatchery program at the CESRF near Cle Elum on the upper Yakima River (river kilometer 297, measuring from the confluence with the Columbia River; Figures 1 and 23) in 1997. This program is a supplementation effort targeting the upper Yakima River population and is designed to test whether artificial propagation can be used to increase natural production and harvest opportunities while limiting ecological and genetic impacts (RASP 1992). It is an integrated hatchery program (Mobrand et al. 2005) because only natural-origin brood-stock are used and returning hatchery-origin adults are allowed to spawn in the wild. The program employs "best practice" hatchery management principles (see Cuenco et al. 1993, Mobrand et al. 2005) including reduced pond densities, strict disease management protocols, random brood-stock selection, and factorial mating (Busack and Knudsen 2007) to maximize effective population size. Fish are reared at the central facility, but released from three acclimation sites located near the central facility at: Easton approximately 25 km upstream of the central facility, Clark Flat about 25 km downstream of the central facility, and Jack Creek about 12 km upstream from the Teanaway River's confluence with the Yakima River (Figure 23). The CESRF collected its first spring Chinook brood-stock in 1997, released its first fish in 1999, and age-4 adults have been returning since 2001. The first generation of offspring of CESRF and wild fish spawning in the wild returned as adults in 2005. The program uses the adjacent, un-supplemented Naches River population as an environmental and wild control system.

To evaluate demographic benefits for spring Chinook, we compared redd count and natural-origin adult return data for the supplemented Upper Yakima and unsupplemented (control) Naches populations using a Before/After Control/Impact (BACI) analysis (Stewart-Oaten et al. 1986; Smith et al. 1993). For redd counts, the before period was defined as 1981 to 2000 and the after period as 2001 to present (hatchery-origin age-4 adults first returned to integrate with natural-origin fish on the natural spawning grounds in 2001). The first natural-origin returns of age-4 fish from these integrated population redds did not occur until 2005 , so the pre- and postsupplementation (before/after) periods for natural-origin return evaluation were defined as 1982 to 2004 and 2005 to present, respectively. The spring Chinook findings described below were published in Fast et al. (2015). We are working with WDFW to incorporate additional out-of-basin control populations in this evaluation and these results will be considered for publication at a later date.

To evaluate fitness parameters for an integrated spring Chinook population, we used methods described in Knudsen et al. (2008), Schroder et al. (2008, 2010, and 2012) and Waters et al. (2015; discussed further below under Hatchery Reform). For coho, we conducted preliminary evaluation of both demographic benefits and some fitness parameters using methods described in Bosch et al. (2007).

Figure 23. Map of the Yakima River Basin, Cle Elum Supplementation and Research Facility (CESRF) locations, and timeline of the spring Chinook supplementation program.

## Results:

Figure 24. Spring Chinook redd counts in the supplemented Upper Yakima (red bar) relative to the unsupplemented Naches (control; blue bar) for the pre- (1981-2000) and post-supplementation (2001-2019) periods.

Figure 25. Natural-Origin returns of Spring Chinook in the supplemented Upper Yakima (red bar) relative to the un-supplemented Naches (control; blue bar) for the pre- (1982-2004) and post-supplementation (20052019) periods.

## Discussion:

Supplementation has increased spring Chinook redd abundance in the Upper Yakima relative to the Naches control system (Figure 24). Redd counts in the postsupplementation period (2001-2019) increased in the supplemented Upper Yakima ( $+82 \%$; $\mathrm{P}=0.026$ ) but the change observed in the un-supplemented Naches control system relative to the pre-supplementation period (1981-2000) was not significant $(+25 \% ; \mathrm{P}=0.308)$. As noted above, spatial distribution of spring Chinook has also increased as a result of supplementation with dramatic increases in redd abundance observed in the Teanaway River (Figure 14) in some years.

Changes in mean natural-origin return abundance in the post-supplementation period (2005-2019) relative to the pre-supplementation period (1982-2004) were not significant in either the supplemented upper Yakima River ( $-1.4 \%$; $\mathrm{P}=0.96$; Figure 25) or the unsupplemented Naches River system ( $-23.2 \%$; $\mathrm{P}=0.36$; Figure 25). We have already noted that limiting factors appear to be inhibiting natural productivity (see status and trend of adult productivity) throughout the Yakima Basin.

With respect to spring Chinook fitness parameters we found the following. The relationships between reproductive traits and body length were not significantly
altered by a single generation of hatchery exposure. However, because hatchery females had smaller body sizes, the distributions of linked traits, such as total gamete mass and fecundity, differed by as much as 0.6 SD , probably resulting in some fitness loss. Our data support the idea that a single generation of state-of-the-art conservation hatchery propagation can produce fish with reproductive traits similar to those of wild fish, given comparable body size (Knudsen et al. 2008). No differences were detected in the egg deposition rates of wild and hatchery origin females, but pedigree assignments based on microsatellite DNA showed that the eggs deposited by wild females survived to the fry stage at a $5.6 \%$ higher rate than those spawned by hatchery-origin females (Schroder et al. 2008). Behavior and breeding success of wild and hatchery-origin males were found to be comparable (Schroder et al. 2010). Large anadromous males produced $89 \%$, jacks $3 \%$, yearling precocious $7 \%$, and sub-yearling precocious $1 \%$ of the fry in our tests suggesting that large anadromous males generate most of the fry in natural settings when half or more of the males present on a spawning ground use this life history strategy (Schroder et al 2012). For additional detail on Spring Chinook findings, see Fast et al. (2015). Finally, in addition to the relative reproductive success (RRS) results reported by Schroder et al. (2008 and 2010) for artificial spawning channel studies, we are also working with our project collaborators at WDFW and CRITFC to evaluate RRS for all integrated hatchery- and natural-origin spawners above Roza Dam for brood years 2007-2011 (see https://www.cbfish.org/Document.mvc/Viewer/P159280 for the latest progress report on this project). We expect to complete genotyping for this work this year and hope to publish findings in 2021. Preliminary results for just the 2007 brood year were reported by CRITFC at the 2017 Science and Management conference and are encouraging: a demographic boost from the CESRF program of 2.2 X with only jacks showing statistically significant differences in RRS between hatchery-reared and natural-origin fish spawning naturally.

The YKFP is presently studying the release of over 1.0 million coho smolts annually from acclimation sites in the Naches and Upper Yakima subbasins. These fish are a combination of in-basin production from brood-stock collected in the vicinity of Prosser Dam plus out-of-basin stock generally reared at Willard or Eagle Creek National Fish Hatcheries and moved to the Yakima Subbasin for final rearing and release. Monitoring of these efforts to re-introduce a sustainable, naturally spawning coho population in the Yakima Basin have indicated that coho returns averaged over 5,300 fish from 1997-2019 (an order of magnitude improvement from the average for years prior to the project) including estimated returns of wild/natural coho averaging over 800 fish annually since 2001 (Figure 4). Coho re-introduction research has demonstrated that hatchery-origin coho, with a legacy of as many as 10 to 30 generations of hatchery-influence, can reestablish a naturalized population after as few as 3 to 5 generations of outplanting in the wild (Bosch et al. 2007). The project is
working to further develop a locally adapted brood-stock and to establish specific release sites and strategies that optimize natural reproduction and survival.

## Effectiveness of Hatchery Reform

Hatcheries have long been a part of the fisheries landscape in the Pacific Northwest with programs originally designed to provide abundant returns for harvest in river ecosystems that were becoming increasingly exploited to serve human needs (Lichatowich 1999). Historically, hatchery programs were designed to release a specified number of juveniles from a central facility, and adult survivors, after providing many fish for harvest during their marine and freshwater migrations, would return to swim-in ladders and adult holding ponds at that same facility to spawn successive generations. Over the past two decades or more, such programs have been the subject of much scientific study regarding risks, such as domestication, they pose to natural populations if these fish spawn in the wild.

The concepts of supplementation and hatchery reform, where hatchery programs could be (re)designed to serve conservation as well as harvest purposes, first began to appear in regional discussions and the literature in the late 1980s and early 1990s (e.g, RASP 1992; Cuenco et al. 1993). In Mobrand et al. (2005) and Paquet et al. (2011), the Hatchery Scientific Review Group (HSRG) described in more scientific detail several principles that should guide integrated (conservation-oriented) hatchery programs which purposefully allow fish to spawn in the wild (note that virtually all of the HSRG recommendations were designed into the integrated CESRF program described above). The HSRG reports also recommended that traditional, harvestoriented hatchery programs should be segregated as much as possible from natural populations to minimize risks by limiting the number of returning fish that escape to natural spawning grounds.

YKFP efforts to monitor and evaluate hatchery reform focus on the CESRF spring Chinook program which was designed explicitly for this purpose from its inception (BPA 1996). To the extent that is practical, we will evaluate similar metrics for the summer/fall run Chinook and coho programs and publish those results in future reports as the Master Plan (Yakama Nation 2019) is implemented and the programs mature over time.

In addition to the integrated (supplementation-S) hatchery program described above for the CESRF, this facility also introduced a segregated "hatchery control" (HC) program in 2002 as recommended by independent scientific review. To protect the integrity of the integrated program evaluation described above, returning HC line fish were either harvested or trapped and removed at the Roza Adult Monitoring Facility
(RAMF); no HC line fish were allowed to escape to the spawning grounds (determination of fish origin was based on a differential marking strategy for $S$ and HC fish; unmarked fish were presumed wild). CESRF-project scientists hypothesized that HC-line fish, which use only returning hatchery-origin fish as brood source, would increasingly diverge in phenotypic and genetic characteristics from wild (WC or wild control) fish with increasing generations of hatchery influence, whereas S-line fish, which use only wild or natural-origin fish for brood source, would remain relatively close in characteristics to wild fish (Figure 26). These hypothetical outcomes were based on hatchery reform theory which suggests that, by using only wild or natural-origin parents to spawn successive generations of fish in the hatchery environment, mean fitness of an integrated population in the natural environment can be maintained relatively close to that of a wild population (Mobrand et al. 2005).

Figure 26. Hypothetical outcomes of trait divergence (domestication effects) over time for a segregated (hatchery-control or HC) line of fish, compared to an integrated (supplementation or S) line of fish and a wild (wild-control or WC) line of fish (D. Fast, Yakama Nation).

This section reports on our efforts to evaluate the effectiveness of hatchery reform measures implemented in the CESRF program.

## Methods:

Methods for enumerating natural- and CESRF-origin fish at Roza Dam were described above (Status and Trend of adult abundance) and in Knudsen et al. (2006).

Methods for evaluating genetic differentiation between the wild founding, integrated, and segregated populations at the CESRF were described in Waters et al. (2015).

A recently developed parameter to monitor the mean fitness of an integrated population in the natural environment is called Proportionate Natural Influence (PNI). PNI is an approximation of the rate of gene flow between the natural environment and the hatchery environment (Busack et al. 2008). The equation describing PNI is

$$
\mathrm{PNI}=\frac{\mathrm{pNOB}}{\mathrm{pNOB}+\mathrm{pHOS}}
$$

where pNOB is the proportion of natural-origin brood-stock and pHOS is the proportion of hatchery-origin spawners. We evaluated PNI for the CESRF program using a pNOB value of 1.0 as only natural-origin fish were used for the integrated program's broodstock.

## Results and Discussion:

For CESRF integrated program return years 2001-2019, PNI averaged $65 \%$ while pHOS averaged $52.9 \%$ (Table 28). As stated in the introduction to this report and in the final Environmental Impact Statement for the Yakima Fisheries Project (BPA 1996), one of the explicit purposes of the project is to test the assumption that new artificial propagation or hatchery reform techniques (Cuenco et al. 1993, Mobrand et al. 2005) can be used to increase natural production without causing significant impacts to existing natural populations. Therefore, it has always been the intent of this project to purposely allow integrated hatchery-origin fish to escape to the natural spawning grounds, i.e., we intentionally maintained a relatively high pHOS rate. Even with a high pHOS relative to recommendations, PNI for the CESRF integrated program remained in the "low hatchery influence for conservation of natural populations" category described by the HSRG (Paquet et al. 2011).

The project will continue to monitor PNI considering factors such as: policy input regarding controlling the number and types of fish allowed to escape to natural spawning areas, meeting overall production goals of the project, guidance from the literature relative to percentage of hatchery fish on the spawning grounds with fitness loss, considerations about what risk is acceptable in a project designed to evaluate impacts from that risk, and the numerous risk containment measures already in place in the project. The State of Washington is using mark-selective fisheries in the lower Columbia River and, when possible, in the lower Yakima River in part as a tool to manage escapement proportions. In 2011, the project implemented an effort to transfer some returning hatchery-origin CESRF adults from Roza Dam to Lake Cle

Elum for the purpose of returning marine derived nutrients and salmon to the watersheds that feed the lake. These measures will also increase PNI in the major spawning areas of the Upper Yakima Basin. Additional adaptive management measures will be considered when and if monitoring and evaluation indicates a need.

1. Proportionate Natural Influence equals Proportion Natural-Origin Brood-stock (PNOB; 1.0 as only NoR fish are used for supplementation line brood-stock) divided by PNOB plus Proportion Hatchery-Origin Spawners (PHOS).
2. This is a rough estimate since Roza counts are not available for 1991.
3. For NoR columns, mean of 1997-present values. For all other columns, mean of 2001-present values.

Both the CESRF integrated and segregated programs have now proceeded for several generations and we can evaluate actual outcomes relative to the hypothetical outcomes given in Figure 26 above. Results were presented in Waters et al. (2015) and empirically demonstrate that using managed gene flow (i.e, using only naturalorigin fish for brood stock) reduced genetic divergence over time in the CESRF integrated (S-line) fish compared to the segregated (HC-line; hatchery-origin parents) fish (Figure 27). The actual results are remarkably consistent with the projected outcomes in Figure 25 demonstrating that there is considerable merit to the concepts behind hatchery reform. While some detractors of hatchery supplementation choose to highlight the differences the CESRF program has found between hatchery and natural-origin fish such as those documented in Knudsen et al. (2006 and 2008), it is important to note that integrated hatchery-origin fish were never expected to be identical to wild fish (Figure 26), but rather similar enough to increase demographic abundance of natural spawners while minimizing risk, which is exactly what the results to date for this project demonstrate (Fast et al. 2015; Koch et al. 2017). Additional evaluation is required before definitive answers to key biological cost and benefit questions relative to using this type of management over the long-term will be known with scientific certainty (Fraser 2008). The YKFP is continuing its collaboration with University of Washington and NOAA scientists to further evaluate and associate genetic divergence results from Waters et al. (2015) with the phenotypic trait analyses in Knudsen et al. (2006 and 2008).

Figure 27. Estimated genetic divergence (variation) for integrated (INT blue), segregated (SEG red), and wild founder (black) spring Chinook in the CESRF program after 4 parental-generations of the hatchery program ( $\mathbf{P} 1=\mathbf{1 9 9 8}, F 1=2002, F 2=2006, F 3=2010, F 4=2014$; updated from Figure 4 in Waters et al. 2015).

Additional information and results from the CESRF program are provided in Appendix B and in Fast et al. (2015).

## Predation Management and Predator Control

## Avian Predation Index

Avian predators are capable of significantly depressing smolt production. The loss of wild spring Chinook salmon juveniles to various types of avian predators has long been suspected as a significant constraint on production and could limit the success of supplementation. Therefore, a long-standing objective of the YKFP has been to monitor, evaluate, and index the impact of avian predation on annual salmon and steelhead smolt production in the Yakima Subbasin. Accurate methods of indexing avian predation across years have been developed.

## Methods:

## River Reach Surveys

The spring river surveys included six river reaches (Table 29) and were generally consistent with avian point count methods described in monitoringmethods.org method 1151. The survey accounts for coverage of approximately 70 miles of the lower portion of the Yakima River.

Table 29. Avian predation river reach survey start and end locations and total reach length.

| Survey Name | River Mile Start | River Mile End | Survey Distance |
| :---: | :---: | :---: | :---: |
| Parker | 107.0 | 93.8 | 13.2 |
| Granger-Emerald | 85.3 | 66.5 | 18.8 |
| Mabton- Prosser | 60.6 | 48.5 | 12.1 |
| Below Prosser | 46.4 | 36.6 | 9.7 |
| Chandler Power Plant -Benton | 36.6 | 30.2 | 6.5 |
| Below Horn Rapids-Van Giesen | 16.8 | 9.4 | 7.4 |

All river reach surveys were conducted by a two-person team from a 16 -foot drift boat or 12-foot raft. Surveys began between 8:00 am and 9:00 am and lasted between 2 to 6 hours depending upon the length of the reach and the water level. All surveys were conducted while actively rowing the drift boat or raft downstream to decrease
the interval of time required to traverse the reach. One person rowed the boat while the other person recorded piscivorous birds encountered.

Table 30. Yakima River Avian Predators.

| Common Name | Scientific Name | Acronym |
| :---: | :---: | :---: |
| Common Merganser | Mergus merganser | COME |
| American White Pelican | Pelecanus erythrorhynchos | AWPE |
| California Gull | Larus californicus | GULL |
| Ring-billed Gull | Larus delawarensis | GULL |
| Belted Kingfisher | Ceryle alcyon | BEKI |
| Great Blue Heron | Ardea herodias | GBHE |
| Double-crested Cormorant | Phalacrocorax auritus | DCCO |
| Black-crowned Night-Heron | Nycticorax nycticorax | BCHE |
| Forster's Tern | Sterna forsteri | FOTE |
| Great Egret | Ardea alba | GREG |
| Hooded Merganser | Lophodytes cucullatus | HOME |
| Bald Eagle | Haliaeetus leucocephalus | BAEA |
| Osprey | Pandion haliaetus | OSPR |
| Caspian Tern | Sterna caspia | CATE |

All birds detected visually or aurally were recorded, including time of observation, species, and sex and age if distinguishable. Leica 10x42 binoculars were used to help observe birds. All piscivorous birds encountered on the river were recorded at the point of initial observation. Most birds observed were only mildly disturbed by the presence of the survey boat and were quickly passed. Navigation of the survey boat to the opposite side of the river away from encountered birds minimized escape behaviors. If the bird attempted to escape from the survey boat by moving down river a note was made that the bird was being pushed. Birds being pushed were usually kept in sight until passed by the survey boat. If the bird being pushed down river moved out of sight of the survey personnel, a note was made, and the next bird of the same species/age/sex to be encountered within the next 1000 meters of river was assumed to be the pushed bird. If a bird of the same species/age/sex was not encountered in the subsequent 1000 meters, the bird was assumed to have departed the river or passed the survey boat without detection, and the next identification of a bird of the same species/age/sex was recorded as a new observation.

## Avian Predator Hotspot Surveys

Two "hotspots" of avian predators have been identified within the Lower Yakima River (Figure 28). These "hotspots" consist of an area below the Chandler fish bypass outfall pipe and below Wanawish Dam. To include data about these hotspots weekly bird counts will be conducted at each of these "hotspots" by YN personnel and BOR personnel. Data will be single day counts of piscivorous birds during the early morning.

## Acclimation Site Surveys

Three Spring Chinook acclimation sites in upper Yakima River (Clark Flat, Jack Creek, and Easton) were surveyed for piscivorous birds from 2004 through 2018 (Figure 1). Surveys were conducted between January 23 and June 10, though dates varied for each site. Three surveys were conducted at the Spring Chinook sites each day, at 8:00 am, 12:00 noon, and 4:00 pm. Surveys were conducted on foot. All piscivorous birds within the acclimation facility, along the length of the artificial acclimation stream, and 50 meters above and 150 meters below the acclimation stream outlet, into the main stem of the Yakima River or its tributaries, were recorded.

Figure 28. Avian Predator Survey Locations.

## Results and Discussion:

## River Reach Surveys

Thirteen different piscivorous bird species were observed on the Yakima River. These included: American White Pelican, Bald Eagle, Black-crowned Night Heron, Belted Kingfisher, Caspian Tern, Common Merganser, Double-crested Cormorant, Forster's Tern, Great Egret, Great Blue Heron, Gull species (California and Ringbill), Hooded Merganser, and Osprey. With the exception of the Forster's Tern, 12 of the species have been observed in most survey years. Graph Data (Figure 29) for river reach surveys represents Avian Predator totals by reach of the lower Yakima River (surveys below Wapato Dam). The total avian predators in the Parker Reach by week are represented in (Figure 30) and numbers increased as river flows decreased. The avian predator counts within the Parker, Granger, Below Prosser, Benton, and Lower Yakima reaches are represented in the bar graphs by their survey acronyms (Figures 31-35).

The Osprey, Great Blue Heron, Common Merganser, and Belted Kingfisher were observed within all six reaches in 2019 while American White Pelicans and Double Crested Cormorants have also been observed in these six reaches in prior years. Common Mergansers were the most abundant Avian Predators in the upper surveyed reaches of the river. The abundance of the Common Merganser in the upper Yakima River in 2019 and all previous years monitored suggest they are the top avian predator for the upper river while American White Pelicans are dominant at Parker and Granger (Figures 31-32).

Gull numbers in the lower Yakima River decreased in 2016 and this trend continued into 2018. In 2019, gulls were again abundant showing increased numbers below Prosser Dam and in the Benton reach at the end of May and in June. Double Crested Cormorants numbers remained consistent in 2019. DCCO numbers remain a concern due to nest takeover of Great Blue Heron Rookeries in various areas along the Yakima River along their high capacity for consuming salmon smolts. Monitoring of the Double Crested Cormorant on the river and in rookeries will be a priority in upcoming years as the Army Corp of Engineers culls and removes breeding habitat at the estuary of the Columbia River in efforts to reduce juvenile salmon predation. These actions may result in displacement and searching out of new habitat for the Cormorants and lead to impacts on salmon in other rivers and basins. The American White Pelican numbers remain consistently high in the lower Yakima River. In the Yakima River pelicans can be seen in groups of over 100 in the Wapato Reach of the river along the borders of the Yakama Indian Reservation.

Figure 32. Granger Reach Avian Predator Species Counts.

Figure 33. Below Prosser Avian Predator Species Counts.

Figure 34. Benton Reach Avian Predator Species Counts.

Figure 35. Lower Yakima Reach Avian Predator Species Counts.

## Hotspot Surveys

Avian predator surveys were conducted at the Chandler fish bypass pipe (river mile $\sim 46$; Figure 36) and Wanawish Dam (river mile ~18.5; Figure 37) hotspots. In 2019 there was an increase in avian predators at both hotspot locations. At Chandler the species diversity stayed the same, where at Wanawish dam there was a decrease in diversity. Only three species were observed at Wanawish in 2019, American White Pelican, Double Crested Cormorant, and Gulls.

Figure 36. Avian Predator Counts at Chandler "hotspot".

Figure 37. Avian Predator Counts at Wanawish Dam "hotspot".

## Acclimation Sites Surveys

At the three Spring Chinook salmon acclimation sites in the upper Yakima River and its tributaries piscivorous bird surveys were conducted over a 3-5 month period in the winter and spring of 2019. The most common species of birds observed at acclimation sites were Bald Eagle, Belted Kingfisher, Common Merganser, Great Blue Heron, Great Egret, and Osprey. Using the assumption that birds frequenting
acclimation ponds are only consuming acclimating juvenile salmon, an average consumption rate can be determined. The average consumption rate can be calculated using the average number of birds at each site, daily energy requirements of the birds and the average size of juvenile salmon.

It was estimated that these bird species together consumed 786 juvenile Chinook at Clark Flat (Table 31). Great Blue Herons had the highest consumption rate, consuming 545 juvenile Chinook. At Easton, it was estimated that 375 juvenile Chinook were consumed. Great Blue Herons and Bald Eagles had the highest consumption rates. Great Blue Herons consumed 122 juvenile Chinook and Bald Eagles consumed 188 juvenile Chinook. Only Belted Kingfishers and Common Mergansers were observed at Jack Creek. It was estimated that they consumed 151 juvenile Chinook. Common Mergansers consumed 137 juvenile Chinook. In 2018, these bird species together consumed 950 juvenile Chinook at Clark Flat, 339 juvenile Chinook at Easton and 961 juvenile Chinook at Jack Creek.

## Fish Predation Index and Predator Control

Fish predators are also capable of significantly depressing smolt production. Thus the YKFP has a long-established objective to monitor, evaluate, and manage the impact of piscivorous fish on annual smolt production of Yakima Subbasin salmon and
steelhead. By indexing the mortality rate of upper Yakima spring Chinook attributable to piscivorous fish in the lower Yakima River, the contribution of in-basin predation to variations in hatchery- and natural-origin spring Chinook smolt-to-adult survival rate can be deduced.

Based on YKFP and WDFW studies of piscivorous fish in the Yakima River Basin (Fritts and Pearsons 2004, 2006, 2008), it was determined that management of the piscivorous fish populations in the area is necessary to improve survival of juvenile salmonids. Initial steps were taken in 2009 to identify locations that would be suitable for a multi-pass removal population study. In early 2010, the YKFP began initial study checks to determine management and study goals for piscivorous fish. Presence and absence of piscivorous fish was determined through electro-fishing various sections of the Yakima River to determine temporal and spatial trends of each species of piscivorous fish. On March 1, 2013, the Washington Fish and Wildlife Commission adopted numerous changes to sport fishing rules, including the elimination of catch restrictions for non-native predators.

## Methods:

Data was collected on piscivorous fish from six electrofishing sites within the Yakima River (Figure 38). Sites were sampled via boat electrofishing through time to assess spatial and temporal patterns of fish abundance and distribution. Each sampling segment was defined by river features of dams and boat launches. The partitioned sample locations consist of four ten mile surveys, one four-mile survey, and one six mile survey (Table 32). Total river mile distance of the combined Yakima River surveys is 50 miles. Survey locations were marked by GPS unit (Garmin GPSmap 78; Garmin International, Olathe, Kansas). After marking sampling reaches, we sample weekly beginning April 2nd and ending June 22nd (dates may vary depending on river stage). (Fish Predators Schei, monitoring methods 47), (Predator Reduction Mclellan, monitoring methods 438).

Sampling was conducted using three different types of vessels and electrofisher; 1. For five of the Yakima River surveys sampling were conducted using a Smith Root SR16H Electrofishing boat equipped with the 7.5 GPP electrofishing unit powered by a $6,000-\mathrm{W}$ Kohler boat generator in; 2. For the Yakima River survey below Prosser sampling was conducted with a 13 foot raft equipped with a smith root $1.5-\mathrm{KVA}$ electrofisher powered by Honda EU2000i generator; 3. For the survey in the McNary pool sampling was conducted with a 16 foot aluminum jet boat equipped with a Smith Root VVP-15B electrofisher powered by a Honda EM3500S generator. Electrofishing settings were adjusted to continuous DC for an output of approximately 700 V and 9-12 A. Invasive species monitoring for the Yakima River will be used as an aid
for tracking changes in fish populations and abundance as the area experiences global climate change.

Figure 38. Fish Predator Survey Locations.
Table 32. Fish Predator Survey River Miles and Distances.

| Survey Name | River Mile Start | River Mile End | Survey Distance Miles |
| :---: | :---: | :---: | :---: |
| Parker | 106.1 | 96.1 | 10 |
| Granger | 85.3 | 75.3 | 10 |
| Above Prosser | 52.4 | 48.4 | 4 |
| Below Prosser | 46.4 | 40.4 | 6 |
| Benton | 31.1 | 21.1 | 10 |
| Lower Yakima | 13.8 | 3.8 | 10 |

Sampling was conducted continuously along river margins when possible. As river stage changes, limiting access to areas within survey segments, continuous electrofishing was not always possible. The start and endpoints of shocker operation within the segment at low river stages was marked, resulting in discontinuous, marked subsegments of electrofisher operation within each survey area.

Data collected during each sampling event consisted of:

- Water Temperature, Dissolved Oxygen, Specific Conductivity gathered by a HACH 30qd water multi-meter
- Water Turbidity gathered by a HACH TSS Handheld Instrument
- River CFS gathered from Bureau of Reclamation gaging stations
- Electrode start and end times
- Numbers and species (Table 33) of all fish observed and their size class greater than or less than 100 mm

At the start of each sampling event a small group of fish were caught and examined to insure that electro-fishing settings were not causing visible injuries. To further insure injuries to fish were minimized, sampling procedures by the National Marine Fisheries Service, "Guidelines for Electrofishing Waters Containing Salmonids Listed under the Endangered Species Act," were followed.

## Results and Discussion:

During surveys of 2018 to 2019 the highest abundance of non-native fish predators were found in the lower reaches of the Yakima River (Figure 39). Piscivorous fish were identified in all 6 survey reaches of the Yakima River. Smallmouth Bass and Channel Catfish were the fish predators found in the highest abundance. These two predators are often considered to be the top salmon predators in the lower Yakima River.

Northern Pike Minnow are the dominant piscivorous fish in the upper portion of the 2019 surveyed reaches of Yakima River (reaches above Prosser Dam). They were the fish predator found in the highest abundance in this area during electro-fishing surveys of 2019. Fish counts for all species observed during the 2019 surveys are given for all reaches in figures 40 through 45.

Figure 39. Fish Predator Counts by Reach and Species.

Figure 40. Parker Reach Fish Counts by Species.

Figure 41. Granger Reach Fish Counts by Species.

Figure 42. Above Prosser Dam Fish Counts by Species.

Figure 43. Below Prosser Dam Fish Counts by Species.

Figure 44. Benton Reach Fish Counts by Species.

Figure 45. Lower Yakima Reach Fish Counts by Species.

Large amounts of introduced fish predators inhabit the Lower Yakima River. Predator numbers tend to increase as time progresses in the spring and summer. Increases in predator abundance in 2019 showed significant correlation with increasing date (Figure 46). These increases also correspond with increasing water temperatures and decreasing river flows.

Figure 46. Total Count of Fish Predators below Prosser Dam.

Smallmouth Bass (SMB) have been found to exhibit a spike in abundance during their spawning periods in the Lower Yakima River. Spawning for Smallmouth Bass is typically between April 1 and July 1. This time period coincides with juvenile salmonid outmigration. This timing provides a readily available prey source for the adult spawning bass and their young recruits. Catch and catch per unit effort for adult Smallmouth Bass begins to rise in the May and June survey periods (Figure 47) as Smallmouth Bass migrate from the Columbia River into the Yakima River to spawn. A rise in catch in adults also correlates with a rise in Yakima River water temperature (Figure 48).

The rise and fall of SMB relative abundance may correlate with the water year of 2015 which produced extremely low flows and high water temperatures and the subsequent high water year in 2016, 2017, and 2018. It is the increase in water temperature in the lower Yakima River which is thought to create productive habitat for SMB. Overall
years there is increased catch success during the late summer and fall months and electro-fishing efforts are increased to maximize catch for managing numbers of SMB in the lower Yakima River. Current efforts to increase salmon populations target SMB populations for management in hopes to increase survival of juvenile salmon outmigration.

## Adaptive Management and Lessons Learned

As noted extensively throughout this report, this project is a collaborative effort involving many agencies, boards, and individuals. As such, project coordination and review of project standards and protocols occurs continually amongst tribal, state, federal, and local entities during normal day-to-day operations of the project. Project results are communicated broadly through the annual science and management conference, technical reports and peer-reviewed journal publications (see references and project-related publications), and via several related web sites described in Appendix A.

We support the principles established in Mobrand et al. (2005) and Paquet et al. (2011) that hatchery programs should be well-defined, scientifically defensible, and use informed decision making tools including adaptive management. Many of these principles were initially published in Cuenco et al. (1993) including specific recommended decision criteria, management protocols, release strategies, and risk management strategies for hatchery programs. We designed a number of these protocols and strategies into the CESRF program and they are clearly contributing to
the results documented here for the Upper Yakima River Basin spring Chinook populations.

Results to date from Yakama Nation supplementation and research efforts in the Yakima River Basin indicate several lessons that may be of broader application on the regional scale.

1. We need to be realistic. Can or should we expect to see "self-sustaining natural populations" in river systems that have been highly altered from their historical state due to ever-increasing human demands on shared resources? In the highly altered systems we live and work in today, hatchery programs provide a necessary means to ameliorate some of the effects of human population growth and development.
2. We need to be honest. Hatchery programs are not the cause of poor productivity. The historical record is replete with documentation (see Dompier 2005) that the region knew exactly what it was doing to natural salmon productivity when development of the region began to intensify with implementation of the Federal Columbia River Power System as early as the 1930s.
3. We need to be patient. Hatchery reform is a relatively new concept and results for longer term 20-25 year efforts such as the Idaho Supplementation Studies (ISS; Venditti et al. 2017) and CESRF program (Fast et al. 2015) are only now becoming available. These programs empirically support the idea that hatchery reform principles can provide the expected benefits.
4. While hatchery supplementation has demonstrated increases in natural production (increased redd and juvenile abundance), supplementation by itself cannot and was never intended to increase natural productivity. To accommodate expanding human population growth and resource demand, it is imperative that we continue and even increase habitat restoration actions to ensure that sufficient spawning and rearing habitat remains available to all naturally spawning fish.
5. Every subbasin, species, and study is unique, so we should not be surprised to see differing results from the many studies of hatchery effects that are ongoing. Researchers need to continue efforts to better understand the root causes of poor natural productivity and the extent to which hatchery programs effect productivity.
6. Evaluation of hatchery programs should include evaluation of environmental and other factors so that hatchery effects are properly reported.
7. Hatchery programs should be regularly evaluated at the local level using expertise across disciplines to collaboratively and iteratively develop appropriate solutions that address the unique problems and limiting factors encountered in each subbasin or tributary that hosts a hatchery program. In the Yakima Basin, this is achieved with the annual Yakima Basin Aquatic Science and Management Conference, and we use the results to evaluate existing goals, objectives, and strategies and to adaptively manage projects in response to new information.

F. Juvenile Outmigration Survival study of Yakima Basin Summer Chinook Smolts to Prosser and McNary Dams, 2009-2019

## Appendix A: Use of Data \& Products

All data and findings should be considered preliminary until results are published in the peer-reviewed literature.

## Where will you post or publish the data your project generates?

## Fish Passage Center

Yakama Nation Fisheries website
RMIS - Regional Mark Information System
StreamNet Database
cbfish.org
PTAGIS Website
Washington State SaSI
A system has been developed that serves Yakima Basin adult abundance and trap sampling (requires login) data for the Prosser and Roza data sets. This system can be accessed at: https://www.yakamafish-nsn.gov/fish-data.

Describe the accessibility of the data and what the requirements are to access them?

- Prosser and Roza dam daily count and trap sample (requires login) data https://www.yakamafish-nsn.gov/fish-data.
- Integration of PIT and CWT release and recovery data with PTAGIS, RMIS, and Fish Passage Center databases
- Production and support of data bases necessary to support BPA quarterly and annual reports (e.g., PISCES, available via CBfish.org)
- Production and support of data bases necessary to support NPCC project proposals (available via CBfish.org)
Additional data is available in the main body and other appendices of this report and by email contact through the data managers (Yakima Basin, contact Bill Bosch, bill bosch@yakama.com; Klickitat Basin, contact Michael Babcock, mbabcock@ykfp.org). Project data managers continue to participate in the Coordinated Assessments process to develop pilot exchange templates for adult and juvenile abundance and productivity parameters. However, we continue to believe that the best way to prioritize our data management work load is to develop databases to store the status and trend data we have been collecting over many years as well as the web tools necessary to access these data in downloadable format. The system we have developed to share Prosser and Roza dam daily count and trap sample data is an example of the progress we are making towards this end.

## Acknowledgments

Monitoring and evaluation efforts for the Cle Elum Supplementation and Research Facility (CESRF) and Yakima River spring Chinook salmon are the result of a cooperative effort by many individuals from a variety of agencies including the Yakama Nation Fisheries Program (YN), the Washington Department of Fish and Wildlife (WDFW), the United States Fish and Wildlife Service (USFWS), the National Oceanic and Atmospheric Administration Fisheries department (NOAA Fisheries) as well as some consultants and contractors.

The core project team includes the following individuals: Dave Fast, Mark Johnston, Bill Bosch, David Lind, Paul Huffman, Joe Hoptowit, and a number of technicians from the YN; Charles Strom and a number of assistants from the CESRF; Anthony Fritts, Gabe Temple, Christopher Johnson, and a number of assistants from the WDFW; Curt Knudsen from Oncorh Consulting and Doug Neeley from IntSTATS Consulting; Sharon Lutz and assistants from the USFWS; and Don Larsen, Andy Dittman, and assistants from NOAA Fisheries. The technicians and assistants are too numerous and varied to mention each by name (and risk leaving some out). However, their hard work in the field is the source of much of the raw data needed to complete this report. We sincerely appreciate their hard work and dedication to this project.

We would especially like to thank former members of the Yakima/Klickitat Fisheries Project, Bruce Watson, Joel Hubble, Bill Hopley, Todd Pearsons, Steve Schroder, and Craig Busack. These individuals put in countless hours of hard work during the planning, design, and implementation of this project. Their contributions helped to lay a solid foundation for this project and our monitoring and evaluation efforts. Dan Barrett (retired) served as the manager of the CESRF from 1997-2002. He helped to lay a solid foundation for the critical work done day in and day out at the Cle Elum facility.

We also need to recognize and thank the Yakama Nation and WDFW for their continued support, and the Columbia River Inter-Tribal Fish Commission, the University of Idaho, the Pacific States Marine Fisheries Commission, Mobrand, Jones, and Stokes, and Central Washington University for their many contributions to this project including both recommendations and data services.

This work is funded by the Bonneville Power Administration (BPA) through the Northwest Power and Conservation Council's (NPCC) Fish and Wildlife Program. Michelle O'Malley is BPA's contracting officer and technical representative (COTR) for this project. David Byrnes and Patricia Smith preceded Michelle in this position and contributed substantially to the project over the years.

#### Abstract

Historically, the return of spring Chinook salmon (Oncorhynchus tshawytscha) to the Yakima River numbered about 200,000 fish annually (BPA, 1990). Spring Chinook returns to the Yakima River averaged fewer than 3,500 fish per year through most of the 1980s and 1990s (less than $2 \%$ of the historical run size).

In an attempt to reverse this trend the Northwest Power and Conservation Council (formerly the Northwest Power Planning Council, NPPC) in 1982 first encouraged Bonneville Power Administration (BPA) to "fund the design, construction, operation, and maintenance of a hatchery to enhance the fishery for the Yakima Indian Nation as well as all other harvesters" (NPPC 1982). After years of planning and design, an Environmental Impact Statement (EIS) was completed in 1996 and the CESRF was authorized under the NPCC's Fish and Wildlife Program with the stated purpose being "to test the assumption that new artificial production can be used to increase harvest and natural production while maintaining the long-term genetic fitness of the fish population being supplemented and keeping adverse genetic and ecological interactions with non-target species or stocks within acceptable limits". The CESRF became operational in 1997. This project is co-managed by the Yakama Nation and the Washington Department of Fish and Wildlife (WDFW) with the Yakama Nation as the lead entity.

This report documents data collected from Yakama Nation tasks related to monitoring and evaluation of the CESRF and its effect on natural populations of spring Chinook in the Yakima Basin through 2017. This report is not intended to be a scientific evaluation of spring Chinook supplementation efforts in the Yakima Basin. Rather, it is a summary of methods and data (additional information about methods used to collect these data may be found in the main section of this annual report) relating to Yakima River spring Chinook collected by Yakama Nation biologists and technicians from 1982 (when the Yakama Nation fisheries program was implemented) to present. Data summarized in this report include:

- Adult-to-adult returns
- Annual run size and escapement
- Adult traits (e.g., age composition, size-at-age, sex ratios, migration timing, etc.)
- CESRF reproductive statistics (including fecundity and fish health profiles)
- CESRF juvenile survival (egg-to-fry, fry-to-smolt, smolt-to-smolt, and smolt-toadult)
- CESRF juvenile traits (e.g., length-weight relationships, migration timing, etc.)
- Harvest impacts

The data presented here are, for the most part, "raw" data and should not be used without paying attention to caveats associated with these data and/or consultation with project biologists. No attempt is made to explain the significance of these data in this report as this is left to more comprehensive reports and publications produced by the project. Data in this report should be considered preliminary until published in the peer reviewed literature.

## Introduction

## Program Objectives

The CESRF was authorized in 1996 under the NPCC's Fish and Wildlife Program with the stated purpose being "to test the assumption that new artificial production can be used to increase harvest and natural production while maintaining the long-term genetic fitness of the fish population being supplemented and keeping adverse genetic and ecological interactions with non-target species or stocks within acceptable limits". The CESRF became operational in 1997. The experimental design calls for a total release of 810,000 smolts annually from each of three acclimation sites associated with the facility (see facility descriptions). To minimize risk of over-collecting brood stock and to maintain lower pond rearing densities, the YKFP policy group took action in 2011 to reduce the release target to 720,000 smolts for brood collection purposes. Female percentage, fecundity and survival rates are expected to result in releases between 720,000 and 810,000 smolts in most years. The first program cycle (brood years 1997 through 2001) also included testing new Semi-Natural rearing Treatments (SNT) against the Optimum Conventional Treatments (OCT) of existing successful hatcheries in the Pacific Northwest. The second program cycle (brood years 2002-2004) tested whether a slower, more natural growth regime could be used to reduce the incidence of precocialism that may occur in hatchery releases without adversely impacting overall survival to adult returns. Brood years 2005-2007 tested survival using different types of feed treatment. Subsequent broods have used a standard treatment in all raceways. With guidance and input from the NPCC and the Independent Scientific Review Panel (ISRP) in 2001, the Naches subbasin population of spring Chinook was established as a wild/natural control. A hatchery control line at the CESRF was also established with the first brood production for this line collected in 2002. Please refer to the project's "Supplementation Monitoring Plan" (Chapter 7 in 2005 annual report on project genetic studies) for additional information regarding these control lines.

## Facility Descriptions

Returning adult spring Chinook are monitored at the Roza adult trapping facility located on the Yakima River (Rkm 205.8). This facility provides the means to monitor every fish returning to the upper Yakima Basin and to collect adults for the CESRF program. All returning CESRF fish (adipose-clipped fish) are sampled for biological characteristics and marks and returned to the river with the exception of fish collected for broodstock, experimental sampling, and all hatchery control line fish. Through 2006, all wild/natural fish passing through the Roza trap were returned directly to the river with the exception of fish collected for broodstock or fish with metal tag detections which were sampled for marks and biological characteristics. Beginning in 2007, all wild/natural fish were sampled (as described above) and tissue samples were collected for a "Whole Population" Pedigree Study of Upper Yakima Spring Chinook (see related project 2009-009-00).

The CESRF is located on the Yakima River just south of the town of Cle Elum (rkm 295.5). It is used for adult broodstock holding and spawning, and early life incubation and rearing. Fish are spawned in September and October of a given brood year (BY). Fish are typically ponded in March or April of BY+1. The juveniles are reared at Cle Elum, marked in October through

December of BY+1, and moved to one of three acclimation sites for final rearing in January to February of BY+2. Acclimation sites are located at Easton (ESJ, rkm 317.8), Clark Flats near the town of Thorp (CFJ, rkm 266.6), and Jack Creek (JCJ, approximately 32.5 km north of Cle Elum) on the North Fork Teanaway River (rkm 10.2). Fish are volitionally released from the acclimation sites beginning on March 15 of BY +2 , with any remaining fish "flushed out" of the acclimation sites by May 15 of $\mathrm{BY}+2$. The annual production goal for the CESRF program is 720,000 to 810,000 fish for release as yearlings at $30 \mathrm{~g} / \mathrm{fish}$ or 15 fish per pound (fpp) although size-at-release may vary depending on experimental protocols (see Program Objectives).

## Yakima River Basin Overview

The Yakima River Basin is located in south central Washington. From its headwaters near the crest of the Cascade Range, the Yakima River flows 344 km ( 214 miles) southeastward to its confluence with the Columbia River (Rkm 539.5; Figure 1).

Figure 1. Yakima River Basin.

Three genetically distinguishable populations of spring Chinook salmon exist in the Yakima basin: the American River, the Naches, and the Upper Yakima Stocks (Figure 1). The upper Yakima was selected as the population best suited for supplementation and associated evaluation and research efforts.

Local habitat problems related to irrigation, logging, road building, recreation, agriculture, and livestock grazing have limited the production potential of spring Chinook in the Yakima River basin. It is hoped that recent initiatives to improve habitat within the Yakima Basin, such as those being funded through the NPCC's fish and wildlife program, the Pacific Coastal Salmon Recovery Fund, and the Washington State salmon recovery fund, will: 1) restore and maintain natural stream stability; 2) reduce water temperatures; 3) reduce upland erosion and sediment delivery rates; 4) improve and re-establish riparian vegetation; and 5) re-connect critical habitats throughout the basin. These habitat restoration efforts should permit increased utilization of habitat by spring Chinook salmon in the Yakima basin thereby increasing fish survival and productivity.

## Adult Salmon Evaluation

## Broodstock Collection and Representation

One of the program's goals is to collect broodstock from a representative portion of the population throughout the run. If the total run size could be known in advance, collecting brood stock on a daily basis in exact proportion to total brood need as a proportion of total run size would result in ideal run representation. Since it is not possible to know the run size in advance, the CESRF program uses a brood collection schedule that is based on average run timing once the first fish arrive at Roza Dam. We have found that, while river conditions dictate run timing (i.e., fish may arriver earlier or later depending on flow and temperature), once fish begin to move at Roza, the pattern in terms of relative run strength over time is very similar from year to year. Thus a brood collection schedule matching normal run timing patterns was developed to assure that fish are collected from all portions of the run (Figure 2).

Figure 2. Mean spring Chinook run timing and broodstock collection at Roza Dam, 2010-2019.
Appendix B. Yakima River / CESRF Spring Chinook Salmon - Yakama Nation Data Summary 2019 Annual Report, May 29, 2020

Another program goal is to take no more than $50 \%$ of the wild/natural adult return to Roza Dam for broodstock. Given this goal and with a set brood collection schedule at Roza Dam, the project imposed a rule that no more than $50 \%$ of the fish arriving on any given day be taken for broodstock. Under-collection relative to the schedule is "carried over" to subsequent days and weeks. This allows brood collection to adjust relative to actual run timing and run strength. Performance across years with respect to these brood collection goals is given in Table 1. Since 2015, the spring Chinook return has been impeded by thermal barriers in the lower Yakima River as warmer air temperatures combined with reduced summer and fall flows have increased water temperatures. Mean daily water temperatures near Prosser (rkm 76 from the mouth of the Yakima R.) have exceeded $68^{\circ} \mathrm{F}$ on several days between June and September during these years (source U.S. BOR hydromet database). This may have caused a large number of fish to stray or be delayed in their migration above Roza Dam.

Table 1. Counts of wild/natural spring Chinook (including jacks), brood collection, and brood representation of wild/natural run at Roza Dam, 1997 - present.

| Year | Trap Count | Brood <br> Take | Brood \% | Portion of run collected: ${ }^{1}$ |  |  | Portion of collection from: ${ }^{2}$ |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  | Early ${ }^{3}$ | Middle ${ }^{3}$ | Late ${ }^{3}$ | Early ${ }^{3}$ | Middle ${ }^{3}$ | Late ${ }^{3}$ |

| 2013 | 2,784 | 398 | 14.3\% | 18.5\% | 13.0\% | 22.0\% | 9.5\% | 75.1\% | 15.3\% |
| 2014 | 4,168 | 384 | 9.2\% | 4.8\% | 8.6\% | 16.9\% | 2.3\% | 80.5\% | 17.1\% |
| 2015 | 3,962 | 442 | 11.2\% | 3.1\% | 8.2\% | 40.6\% | 2.0\% | 59.9\% | 38.1\% |
| 2016 | 2,712 | 376 | 13.9\% | 5.3\% | 14.8\% | 18.6\% | 2.5\% | 84.7\% | 12.9\% |
| 2017 | 1,711 | 382 | 22.3\% | 53.6\% | 19.0\% | 45.4\% | 11.4\% | 69.9\% | 18.7\% |
| 2018 | 827 | 294 | 35.6\% | 3.0\% | 33.7\% | 87.6\% | 0.3\% | 75.1\% | 24.6\% |
| 2019 | 703 | 312 | 44.4\% | 48.1\% | 46.3\% | 29.1\% | 8.3\% | 84.3\% | 7.3\% |

1. This is the proportion of the earliest, middle, and latest running components of the entire wild/natural run which were taken for broodstock. Ideally, this collection percentage would be equal throughout the run and would match the "Brood \%".
2. This is the proportion of the total broodstock collection taken from the earliest, middle, and latest components of the entire wild/natural run. Ideally, these proportions would match the definitions for early, middle, and late given in 3.
3. Early is defined as the first $5 \%$ of the run, middle is defined as the middle $85 \%$, and late as the final $10 \%$ of the run.

## Natural- and Hatchery-Origin Escapement

While the project does not actively manage for a specific spawning escapement proportion (natural- to hatchery-origin adults), we are monitoring the proportion of natural influence (PNI; Table 2). The project will adaptively manage this parameter considering factors such as: policy input regarding surplusing of fish, meeting overall production goals of the project, guidance from the literature relative to percentage of hatchery fish on the spawning grounds with fitness loss, considerations about what risk is acceptable in a project designed to evaluate impacts from that risk, and the numerous risk containment measures already in place in the project. The State of Washington is using mark-selective fisheries in the lower Columbia River and, when possible, in the lower Yakima River in part as a tool to manage escapement proportions. In 2011, the project initiated an effort to transfer some returning hatchery-origin CESRF adults from Roza Dam to Lake Cle Elum for the purpose of returning marine derived nutrients and salmon to the watersheds that feed the lake. This effort will also increase PNI in the major spawning areas of the Upper Yakima Basin. Natural- and hatchery-origin escapement to the upper Yakima Basin is given in Table 2. Wild/natural escapement to the Naches subbasin is given in Table 3.

Table 2. Escapement (Roza Dam counts less brood stock collection and harvest above Roza) of natural(NoR) and hatchery-origin (HoR) spring Chinook to the upper Yakima subbasin, 1982 - present.

1. Proportion Natural Influence equals Proportion Natural-Origin Broodstock (pNOB; 1.0 as only NoR fish are used for supplementation line brood stock) divided by pNOB plus Proportion Hatchery-Origin Spawners (pHOS).
2. This is a rough estimate since Roza counts are not available for 1991.
3. For NoR columns, mean of 1997-present values. For all other columns, mean of 2001-present values.

## Adult-to-adult Returns

The overall status of Yakima Basin spring Chinook is summarized in Table 3. Adult-to-adult return and productivity data for the various populations are given in Tables 4-8 (Means are for 1988 to present).

Table 3. Yakima River spring Chinook run (CESRF and wild, adults and jacks combined) reconstruction, 1990-present.

1. River Mouth run size is the greater of the Prosser count plus lower river harvest or estimated escapement plus all known harvest and removals.
2. Estimated as the average number of fish per redd in the upper Yakima times the number of redds between the Naches confluence and Roza Dam.
3. Roza removals include harvest above Roza, hatchery removals, and/or wild broodstock removals.
4. Estimated escapement into the upper Yakima River is the Roza count, less harvest or broodstock removals above Roza Dam except in 1991 when Upper Yakima River escapement is estimated as the (Prosser count - harvest above Prosser - Roza subtractions) times the proportion of redds counted in the upper Yakima.
5. Naches River escapement was estimated as the Prosser count, less harvest above Prosser and the Roza counts, except in 1982,1983 and 1990 when it was estimated as the upper Yakima fish/redd times the Naches redd count.
6. Recent 10 -year average (2010-2019).

Appendix B. Yakima River / CESRF Spring Chinook Salmon - Yakama Nation Data Summary
2019 Annual Report, May 29, 2020

Estimated spawners for the Upper Yakima River are calculated as the estimated escapement to the Upper Yakima plus the estimated number of spawners in the Upper Yakima between the confluence with the Naches River and Roza Dam (Table 3). Total returns are based on the information compiled in Table 3. Age composition for Upper Yakima returns is estimated from spawning ground carcass scale samples for the years 1982-1996 (Table 11) and from Roza Dam brood stock collection samples for the years 1997 to present (Table 13). Since age- 3 fish (jacks) are not collected for brood stock in proportion to the jack run size, the proportion of age-3 fish in the upper Yakima for 1997 to present is estimated using the proportion of jacks (based on visual observation) counted at Roza Dam relative to the total run size.

Table 4. Adult-to-adult productivity indices for upper Yakima wild/natural stock.

| Brood Year | Estimated <br> Spawners | Estimated Yakima R. Mouth Returns |  |  |  | Returns/ <br> Spawner |

1. The mean jack proportion of spawning escapement from 1999-2019 was 0.22 (geometric mean 0.17).

Estimated spawners for the Naches/American aggregate population (Table 7) are calculated as the estimated escapement to the Naches Basin (Table 3). Estimated spawners for the individual Naches and American populations are calculated using the proportion of redds counted in the Naches Basin (excluding the American River) and the American River, respectively (see Table 31). Total returns are based on the information compiled in Table 3. Age composition for Naches Basin age-4 and age-5 returns are estimated from spawning ground carcass scale samples (see Tables 9-12). The proportion of age-3 fish is estimated after reviewing jack count (based on visual observations) data at Prosser and Roza dams. Since sample sizes for carcass surveys in the American and Naches Rivers can be very low in some years (Tables 9 and 10), it is recommended that the data in Tables 5 and 6 be used as indices only. Table 7 likely provides the most accurate view of overall productivity rates in the Naches River Subbasin.

Table 5. Adult-to-adult productivity indices for Naches River wild/natural stock.

1. The mean jack proportion of spawning escapement from 1999-2019 was 0.09.

Estimated spawners at the CESRF are the total number of wild/natural fish collected at Roza Dam and taken to the CESRF for production brood stock. Total returns are based on the information compiled in Table 3 and at Roza dam sampling operations. Age composition for CESRF fish is estimated using scales and PIT tag detections from CESRF fish sampled passing upstream through the Roza Dam adult monitoring facility.

1. 357 or $48 \%$ of these fish were jacks.
2. Geometric mean.

## Age Composition

Comparisons of the age composition in the Roza adult monitoring facility (RAMF) samples and spawning ground carcass recovery samples show that older, larger fish are recovered as carcasses on the spawning grounds at significantly higher rates than younger, smaller fish (Knudsen et al. 2003 and Knudsen et al. 2004). Based on historical scale-sampled carcass recoveries between 1986 and 2016 (there were no carcass recoveries in 2017 or 2018), age composition of American River spring Chinook has averaged $1,44,54$, and 1 percent age- $3,-4,-5$, and -6 , respectively (Table 9). Naches system spring Chinook averaged $2,61,36$ and 0.5 percent age- $3,-4,-5$ and -6 , respectively (Table 10). The upper Yakima River natural origin fish averaged 8,88 , and 4 percent age- $3,-4$, and -5 , respectively (Table 11). While these ages are biased toward the older age classes, we believe the bias is approximately equal across populations and is a good relative indicator of differences in age composition between populations. The data show distinct differences with the American River population having the oldest age of maturation, followed closely by the Naches system and then the upper Yakima River which has significantly more age-3's, fewer age-5's and no age-6 fish.

Table 9. Percentage by sex and age of American River wild/natural spring Chinook carcasses sampled on the spawning grounds and sample size ( n ), 1986-present.

Appendix B. Yakima River / CESRF Spring Chinook Salmon - Yakama Nation Data Summary 2019 Annual Report, May 29, 2020

Carcasses from upper Yakima River CESRF origin fish allowed to spawn naturally have also been sampled since age-4 adults began returning in 2001. These fish averaged 13, 85 , and 1 percent age- $3,-4$, and -5 , respectively (Table 12) from 2001-2014 compared to 8,88 , and 4.3 percent respectively for their wild/natural counterparts in the upper Yakima for the same years (Table 11). The observed difference in age distribution between wild/natural and CESRF sampled on the spawning grounds may be due in part to the carcass recovery bias described above. A better comparison of age distribution between upper Yakima wild/natural and CESRF fish is from samples collected at Roza Dam which are displayed in Tables 13 and 14. However, it must be noted that jacks (age-3 males) were collected at Roza in proportion to run size from 1997 to 1999, but from 2000-present we have attempted to collect them at their mean brood representation rate (approximately $7 \%$ of the spawning population). Age- 3 females do occur rarely in the Upper Yakima population, but it is likely that the data in Table 13 slightly over-represent the proportion of age- 3 females due to human error associated with scale collection, handling, processing, and management and entry of these data.

Table 12. Percentage by sex and age of upper Yakima River CESRF spring Chinook carcasses sampled on the spawning grounds and sample size ( $\mathbf{n}$ ), 2001-present.

Appendix B. Yakima River / CESRF Spring Chinook Salmon - Yakama Nation Data Summary 2019 Annual Report, May 29, 2020

## Sex Composition

In the American River, the mean proportion of males to females in wild/natural carcasses sampled on the spawning grounds from 1986-2016 was 41:59 for age-4 and 33:67 for age- 5 spring Chinook (Table 15). In the Naches River, the mean proportion of males to females was 41:59 for age-4 and 27:73 for age-5 fish (Table 16). In the upper Yakima River, the mean proportion of males to females was 33:67 for age-4 and 23:77 for age-5 fish (Table 17). Collection of carcass samples from the spawning grounds throughout the Yakima Basin did not occur in 2017 or 2018.

For upper Yakima fish collected at Roza Dam for brood stock or research purposes from 1997-2017, the mean proportion of males to females was 38:62 and 35:65 for age-4 fish from the wild/natural and CESRF populations, respectively (Tables 19 and 20). For these same samples, the mean proportion of males to females was $38: 62$ and $41: 59$ for age- 5 fish from the wild/natural and CESRF populations (excluding years with very small age-5 sample sizes), respectively (Tables 19 and 20). For adult fish, the mean proportion of males to females in spawning ground carcass recoveries was substantially lower than the ratio found at RAMF (Tables 17 and 19), indicating that sex ratios estimated from hatchery origin carcass recoveries were biased due to female carcasses being recovered at higher rates than male carcasses (Knudsen et al, 2003 and 2004). Again, despite these biases, we believe these data are good relative indicators of differences in sex composition between populations and between years.

Sample sizes for Tables 15-20 were given in Tables 9-14. As noted earlier, few age-6 fish are found in carcass surveys and those that have been found were located in the American and Naches systems. The data indicate that age- 3 females may occasionally occur in the upper Yakima and, to a lesser extent, the Naches systems.

## Size at Age

Prior to 1996, samplers were instructed to collect mid-eye to hypural plate (MEHP) lengths from carcasses surveyed on the spawning grounds. From 1996 to present the method was changed and post-eye to hypural plate (POHP) lengths have been recorded. Mean POHP lengths averaged 39, 61, and 76 cm for age-3, -4 , and -5 males, and averaged 63 and 72 cm for age- 4 and -5 females, respectively, from carcasses sampled on the spawning grounds in the American River from 1996-2016 (Table 21). In the Naches River, mean POHP lengths averaged 42, 60, and 76 cm for age- $3,-4$, and -5 males, and averaged 61 and 72 cm for age-4 and -5 females, respectively (Table 22). For wild/natural spring Chinook sampled on the spawning grounds in the upper Yakima River, mean POHP lengths averaged 44, 60, and 72 cm for age- $3,-4$, and -5 males, and averaged 59 and 69 cm for age- 4 and -5 females, respectively (Table 23). Beginning in 2012, carcass sampling in the Upper Yakima was scaled back considerably as large numbers of escaping fish are sampled at Roza Dam (Tables 27-28). From 2001-2018, CESRF fish returning to the upper Yakima have been generally smaller in size-at-age than their wild/natural counterparts (Tables 25-28).

Table 21. Counts and mean mid-eye (MEHP) or post-orbital (POHP) to hypural plate lengths (cm) of American River wild/natural spring Chinook from carcasses sampled on the spawning grounds by sex and age, 1986-present.

[^3]Table 22. Counts and mean mid-eye (MEHP) or post-orbital (POHP) to hypural plate lengths (cm) of Naches River wild/natural spring Chinook from carcasses sampled on the spawning grounds by sex and age, 1986-present.

## Migration Timing

Wild/natural spring Chinook adults returning to the upper Yakima River have generally shown earlier passage timing at Roza Dam than CESRF spring Chinook (Figures 2 and 3).

Figure 3. Proportionate passage timing at Roza Dam of wild/natural and CESRF adult spring Chinook (including jacks), 2010-2019.

Table 29. Comparison of $5 \%$, median ( $50 \%$ ), and $95 \%$ passage dates of wild/natural and CESRF adult spring Chinook (including jacks) at Roza Dam, 1997-Present.

1. In 2000 all returning CESRF fish were age-3 (jacks).
2. Mean daily water temperatures at Kiona (rkm 40 from the mouth of the Yakima R.) exceeded $70^{\circ} \mathrm{F}$ every day from May 21 to August 29, 2015 (source U.S. BOR hydromet database) causing delayed passage for late migrating fish.

## Spawning Timing

Median spawn timing for CESRF spring Chinook is earlier than that observed for wild/natural fish in the Upper Yakima River. These differences are due in part to environmental conditions and spawning procedures at the hatchery. It must also be noted that spawning dates in the wild are only a coarse approximation, derived from weekly redd counts not actual dates of redd deposition. A clear delineation of wild/natural spawn timing between subbasins is apparent, with American River fish spawning about 1 month earlier than Naches Basin fish which spawn about 2 weeks earlier than Upper Yakima fish.
Table 30. Median spawn ${ }^{1}$ dates for spring Chinook in the Yakima Basin.

| Mean | 15-Aug | 12-Sep | 25-Sep | 22-Sep |

1. Approximately one-half of the redds in the system were counted by this date and one-half were counted after this date. For the CESRF, approximately one-half of the total broodstock were spawned by this date and one-half were spawned after this date.
2. Spawner surveys impacted by fires; especially in the Naches system.

## Homing

A team from NOAA fisheries conducted studies to determine the spatial and temporal patterns of homing and spawning by wild and hatchery-reared salmon released from CESRF facilities from 2001 to 2010. These studies collected GPS information on each redd and carcass recovered within a survey reach. Carcass surveys were conducted annually in late-September to early October by NOAA personnel in cooperation with Yakama Nation survey crews over five different reaches of the upper Yakima River and recorded the location of each redd flagged and carcass recovered. For each carcass sex, hatchery/wild, male status (full adult, jack, mini-jack), and CWT location was recorded. Data collected on the body location of CWTs allowed the identification of the release site of some fish. While these studies were not designed to comprehensively map carcasses and redds in all spawning reaches in the upper watershed, preliminary data indicate that fish from the Easton, Jack Creek, and Clark Flat acclimation facilities had distinct spawner distributions. A more complete description of this project is available from NOAA fisheries and in this publication:

Dittman, A. H., D. May, D. A. Larsen, M. L. Moser, M. Johnston, and D. Fast. 2010. Homing and spawning site selection by supplemented hatchery- and naturalorigin Yakima River spring Chinook salmon. Transactions of the American Fisheries Society 139:1014-1028.

## Straying

The regional PTAGIS (PIT tag) and RMIS (CWT) databases were queried in December 2019 to determine the number of CESRF releases not returning to the Yakima River Basin (RMIS CWT data are incomplete for the most recent years). For adult (age-3, -4, or -5) PIT tagged fish, a stray is defined as detection at an out-of-basin facility in the Snake (Ice Harbor or Lower Granite) or Upper Columbia (Priest Rapids, Rock Island, or Wells) without a subsequent detection at Prosser or Roza Dam. For coded-wire tagged fish, a stray is generally defined as a tag recovery in tributaries of the Columbia River upstream (and including the Snake River Basin) of its' confluence with the Yakima River. Marked (adipose fin clipped) fish are occasionally found during carcass surveys in the Naches River system. All marked fish observed in spawning ground carcass surveys in the Naches Basin are assumed to be CESRF fish and are used to estimate in-basin stray rates.

Table 32. Estimated number of PIT- and CWT-tagged CESRF fish not returning to the Yakima River Basin (strays), and marked fish sampled during spawner surveys in the Naches Basin, per number of returning fish, brood years 1997-present.

[^6]
## CESRF Spawning and Survival

As described earlier, a portion of natural- and hatchery-origin (NoR and HoR, respectively) returning adults are captured at Roza Dam during the adult migration and taken to the CESRF for broodstock and/or research purposes. Fish are held in adult holding ponds at the CESRF from capture in the spring and summer until spawning in September through early October. All mortalities during the holding period are documented by sex and origin. During the spawning period data are kept on the number of males and females of each origin used for spawning or other purposes. All females have samples taken that are later evaluated for presence of BKD-causative agents. Eggs from females with high BKD-presence indicators are generally excluded (see Female BKD Profiles). Once fertilized, eggs are placed in holding troughs until shock time. Dead eggs are then sorted and hand-counted. All live eggs are machine counted, sorted into two lots per female (treatment and control) and placed into incubation (heath) trays. Using hand counts of egg samples from a subsample of female egg lots, WDFW staff determined that machine counts are biased and that the best approximation of live egg counts is given by the following equation:
$\left(\left(\frac{\text { no. eggs in subsample }}{\text { wt. of subsample }} *\right.\right.$ total egg mass wt $\left.) * 0.945\right)$-dead eggs
where
the first 3 parameters are from egg samples taken from females at spawn time, dead eggs are the number of dead or unfertilized eggs counted at shock time, and the 0.945 value is a correction factor from 1997 and 2000 WDFW studies.

Total egg take is calculated as the total number of live eggs, dead eggs, and all documented egg loss (e.g. spilled at spawn time, etc.). Heath trays are periodically sampled during incubation and dead fry are culled and counted. The number of live eggs less documented fry loss is the estimate of the number of fry ponded. Once fry are ponded, mortalities are counted and recorded daily during the rearing period. Fish are hand counted in the fall prior to their release as they are 100 -percent marked. This handcount less documented mortalities from marking through release is the estimate of smolts released. Survival statistics by origin and life-stage are given in Tables 33 and 34.

Table 33. Cle Elum Supplementation and Research Facility spawning and survival statistics (NoR brood only), 1997 - present.

1. Total collected minus total mortalities does not equal total spawned. This is because some fish are used in the spawning channel, some have been released back to the river, and some have not been used.
2. Includes jacks.
3. All documented egg loss at spawn time plus dead eggs counted at shock divided by the estimated total egg take.
4. Based on physical counts at mark time and all documented rearing mortality from ponding to release, except for BY2013 it is live eggs (est.) minus fry loss.
5. Approximately one-half of these were jacks, many of which were not used in spawning.
6. Approximately 45,000 smolts lost at Jack Creek due to frozen equipment in February, 2006.
7. EWOS feed treatment had high mortality and was discontinued in May 2007; resulted in lower survival to release.
8. Approximately 36,000 NoR (Table 33) and $12,000 \mathrm{HoR}$ (Table 34) fish were culled in July 2009 to reduce pond densities; these fish were added back in to fry-smolt and live-egg-smolt survival calculations.
9. Table 34 -- From 2002 to present this is the estimated total egg take from all HxH crosses. Due to the large surplus of eggs over the approximately 100 K needed for the HxH line, many surplus fry were planted in nearby land-locked lakes and some surplus eggs were destroyed.
Appendix B. Yakima River / CESRF Spring Chinook Salmon - Yakama Nation Data Summary
2019 Annual Report, May 29, 2020

See footnotes for Table 33 above.
10. Table 34 -- For only those HxH fish which were actually ponded.
11. The number of segregated, hatchery-control line brood raceways was increased from 2 to 4 for this brood due to overall brood shortages.

## Female BKD Profiles

Adults used for spawning and their progeny are tested for a variety of pathogens accepted as important in salmonid culture (USFWS Inspection Manual, 2003), on a population or "lot" basis. At the CESRF, and in the Columbia Basin it has been accepted that the most significant fish pathogen for spring Chinook is Renibacterium salmoninarum, the causative agent of Bacterial Kidney Disease (BKD). All adult females and 30-60 juveniles from each acclimation pond are individually tested for levels of Renibacterium salmoninarum using ELISA (Enzyme linked Immuno-sorbant Assay). ELISA data are reported annually to CESRF and YKFP staff for management purposes, eventual data entry and comparisons of ponds and rearing parameters. To date, no significant occurrences of other pathogens have been observed. Periodic field exams for external parasites and any signs of disease are performed on an "as needed" basis. Facility staff have been trained to recognize early signs of behavior changes or diseases and would report any abnormalities to the USFWS, Olympia Fish Health Center for further diagnostic work.

Adult females are ranked from 0 to 13 based on the relative amounts of BKD in the tissue samples of the tested fish. All BKD ranks below 5 are considered low risk for transferring significant BKD organisms through the egg to cause significant disease in progeny receiving proper care. The progeny of adults with BKD rank 6 are considered to be moderate risk and those with BKD rank 7 or greater are considered to be high risk. Given these data, the CESRF chose to rear only the progeny of females with a BKD rank of 6 or less through brood year 2001. Beginning with brood year 2002, the progeny of fish with BKD rank 6 (moderate risk) or greater (high risk) have not been used for production purposes at the CESRF. For additional information, see Appendix B.

Figure 4. Proportion of wild/natural females spawned at CESRF by BKD rank, 1997 - present.

## Fecundity

Fish collected at Roza Dam are taken to the CESRF for spawning and/or research purposes. Egg loss due to spill or other reasons at spawn time is documented. When eggs are shocked, unfertilized (dead) eggs are hand-counted and remaining eggs are machine counted. Due to error associated with machine counts, average fecundity is calculated using spawn-time egg sample data (see discussion above under CESRF Spawning and Survival) and adding in documented egg loss for all females divided by the number of females $(\mathrm{N})$ in the sample.

Table 35. Mean fecundity by age of adult females (BKD rank < 6) spawned at CESRF, 1997-present.

| Brood <br> Year | Wild/Natural (SN) |  |  |  |  |  | CESRF (HC) |  |  |  |  |  |

1. Given their length and fecundity, these fish may have been incorrectly aged.

## Juvenile Salmon Evaluation

## Food Conversion Efficiency

At the end of each month that fish are in the rearing ponds at the CESRF or the acclimation sites, a sample of fish are weighed and measured to estimate growth. These data, in addition to monthly mortality and pond feed data are entered into the juvenile growth and survival tracking database. Hatchery managers monitor food conversion (total pounds fed during a month divided by the total pounds gained by the fish) to track how well fish are converting feed into body mass and to evaluate the amount of feed that needs to be provided on a monthly basis. Average monthly food conversion and growth statistics for the CESRF facilities by brood year are provided in the following tables and figures.

Table 36. Mean food conversion (lbs fed/lbs gained) of CESRF juveniles by brood year and growth month, 1997 - present.

| Brood <br> Year | Apr | May | Jun | Jul | Aug | Sep | Oct | Nov | Dec | Jan | Feb | Mar |

## Length and Weight Growth Profiles

Figure 5. Mean fork length (cm) of CESRF juveniles by brood year and growth month, 1997 - present.

Figure 6. Mean Weight (fish/lb) of CESRF juveniles by brood year and growth month, 1997 - present.

## Juvenile Fish Health Profile

Approximately 50-100 juveniles were sacrificed for juvenile fish health samples in the spring (usually in March) of their release year. Tissue samples from these fish were processed at USFWS laboratories in Olympia, Washington for presence of bacterial kidney disease (BKD) using enzyme-linked immunosorbent assay (ELISA) tests (see Female BKD Profiles and Appendix B for additional discussion). Fish were ranked high, moderate, or low (risk) based on the relative amounts of BKD in the tissue samples of the tested fish. These relative risk levels assume a good fish culture and rearing environment (i.e., water temperature and flows, nutrition, densities, etc. all must be conducive to good fish health). As indicated in Figure 7, juvenile fish released from the CESRF are largely in the low risk category for all brood years sampled to date.

Figure 7. ELISA-risk profile of CESRF juveniles by brood year, 1997 - present (data source: USFWS).
CESRF Spring Chinook juveniles released from Acclimation Sites (ELISA summary by Brood Year)

## Incidence of Precocialism

For brood years 2002-2004, the YKFP tested two different feeding regimes to determine whether a slowed-growth regime reduces the incidence of precocialism without a reduction in postrelease survival. The two growth regimes tested were a normal (High) growth regime resulting in fish which were about 30/pound at release and a slowed growth regime (Low) resulting in fish which were about 45/pound at release. As a critical part of this study, a team from NOAA Fisheries conducted research to characterize the physiology and development of wild and hatchery-reared spring Chinook salmon in the Yakima River Basin. While precocious male maturation is a normal life-history strategy, the hatchery environment may be potentiating this developmental pathway beyond natural levels resulting in potential loss of anadromous adults, skewing of sex ratios, and negative genetic and ecological impacts on wild populations. Previous studies have indicated that age of maturation is significantly influenced by endogenous energy stores and growth rate at specific times of the year. These studies will help direct rearing strategies at the CESRF to allow production of hatchery fish with physiological and life-history attributes that are more similar to their wild cohorts.

## CESRF Smolt Releases

The number of release groups and total number of fish released diverged from facility goals in some years. In brood year 1997, the Jack Creek acclimation facility was not yet complete and project policy and technical teams purposely decided to under-collect brood stock to allow a methodical testing of the new facility's operations with less risk to live fish, which resulted in the stocking of only 10 of the 18 raceways. In brood year 1998, the project did not meet facility release goals due to a biological specification that no more than $50 \%$ of returning wild fish be taken for brood stock. As a result only 16 raceways were stocked with progeny of the 1998 brood. In the same year, raceway 4 at the Jack Creek acclimation site suffered mechanical failures causing loss of flow and reduced oxygen levels and resulted in the loss of approximately one-half the fish in this raceway prior to release. In the drought year of 2001, a large number of returning adults presented with high enzyme-linked immunosorbent assay (ELISA) levels of Renibacterium salmoninarum, the causative agent of bacterial kidney disease (BKD). The progeny of these females were purposely destroyed. As a result, only nine raceways were stocked with fish. The project decided to use the fish from an odd raceway for a predator avoidance training sub-experiment (these fish were subsequently acclimated and released from the Easton acclimation site).

1. Brood years 1997-2001: Optimum Conventional Treatment (OCT). Brood Years 2002-2004: Normal (High) growth. Brood Years 2005-2012: Normal feed at Cle Elum or accl. sites.
2. Brood years 1997-2001: Semi-natural Treatment (SNT). Brood Years 2002-2004: Slowed (Low) growth. Brood Year 2005, 2007-2012: saltwater transition feed at accl. Sites; BY2014-present: BioPRO vs BioVIT diet. Brood Year 2006: EWS diet at CESRF through May 3, 2007.
3. At the Jack Creek acclimation site only 4 of 6 raceways were stocked, and raceway 4 suffered mechanical failures resulting in the loss of about 20,000 OCT (control) fish.
4. High BKD incidence in adult broodstock reduced production to just 9 ponds (Clark Flat 1-2, Jack Creek, and Easton). Easton ponds were used for predator avoidance trained (PAT) fish and a single Cle Elum pond was spread between 6 ponds at Easton with crowders used to simulate pond densities for fish at other acclimation sites. These releases were excluded from mean pond density calculations by treatment.
5. At the Jack Creek acclimation site raceway 3 suffered mechanical failures resulting in the loss of about 45,000 high-growth (control) fish.

Mean length and weight at release by brood year are shown in Figures 5 and 6 under Juvenile Salmon Evaluation, length and weight growth profiles. Mark information and volitional release dates are given in Appendix A.

## Smolt Outmigration Timing

The Chandler Juvenile Monitoring Facility (CJMF) located on the fish bypass facility of Chandler Canal at Prosser Dam (Rkm 75.6; Figure 1) serves as the cornerstone facility for estimating smolt production in the Yakima Basin for several species and stocks of salmonids. Daily species counts in the livebox at the CJMF are expanded by the canal entrainment, canal
survival, and sub-sampling rates in order to estimate daily passage at Prosser Dam (Neeley 2019). Expansion techniques for deriving Chandler smolt passage estimates are continually being reviewed and revised to incorporate new information. A subset of fish passing through the CJMF is sampled for presence of internal (CWT or PIT) or external (fin-clip) marks. All fish with marks are assumed to be of hatchery origin; otherwise, fish are presumed to be of natural origin.

Figure 8. Mean flow approaching Prosser Dam versus mean estimated smolt passage at Prosser of aggregate wild/natural and CESRF spring Chinook for outmigration years 1999-2019.

## Smolt-to-Smolt Survival

OCT-SNT Treatment (Brood Years 1997-2001, Migration Years 1999-2003)
Results of this experiment have been published:
Fast, D. E., D. Neeley, D.T. Lind, M. V. Johnston, C.R. Strom, W. J. Bosch, C. M. Knudsen, S. L. Schroder, and B.D. Watson. 2008. Survival Comparison of Spring Chinook Salmon Reared in a Production Hatchery under Optimum Conventional and Seminatural Conditions. Transactions of the American Fisheries Society 137:1507-1518.

Abstract - We found insufficient evidence to conclude that seminatural treatment (SNT; i.e., rearing in camouflage-painted raceways with surface and underwater structures and underwater feeders) of juvenile Chinook salmon Oncorhynchus tshawytscha resulted in higher survival indices than did optimum conventional treatment (OCT; i.e., rearing in concrete raceways with surface feeding) for the specific treatments and environmental conditions tested. We reared spring Chinook salmon from fry to smolt in paired raceways under the SNT and OCT rearing treatments for five consecutive years. For four to nine SNT and OCT raceway pairs annually, we used passive integrated transponder, coded wire, and visual implant elastomer tags to compare survival indices for juvenile fish from release at three different acclimation sites 340-400 km downstream to passage at McNary Dam on the Columbia River, and for adults from release to adult return to Roza Dam in the upper Yakima basin. The observed differences in juvenile and adult survival between the SNT and OCT fish were either statistically insignificant, conflicting in
their statistical significance, or explained by significant differences in the presence of the causative agents of bacterial kidney disease in juvenile fish at release.

High-Low Growth Treatment (Brood Years 2002-04, Migration Years 2004-2006)
Two early-rearing nutritional regimes were tested using hatchery-reared Yakima Upper spring Chinook for brood years 2002 through 2004. A low nutrition-feeding rate (low treatment or low) was administered at the Cle Elum Hatchery through early rearing to determine whether that treatment would reduce the proportion of precocials produced compared to a conventional feeding rate during early rearing. The conventional feeding rate, which served as a control treatment, is referred to here as a high nutrition-feeding rate (high treatment or high). Feed was administered at a rate of 10 grams/fish for the low treatment and 15 grams/fish for the high treatment through mid-October, after which sufficient feed was administered to both sets of treated fish to meet their feeding demands. The treatments were allocated within pairs of raceways (blocks), there being a total of nine pairs. The Low nutritional feed (Low) had a significantly lower release-to-McNary survival than did the High nutritional feed (High), respective survivals being $18.1 \%$ and $21.2 \%$ ( $\mathrm{P}<0.0001$; D. Neeley, Appendix B of 2008 annual report). The Low survival to McNary was consistently lower than the High at all sites in all years. Low-treated fish were smaller fish at the time of release and had somewhat later McNary passage times than high-treated fish.

## Control versus Saltwater Transfer Treatment (Brood Years 2005, 2007- 2010; Migration Years

 2007, 2009-2013)Prior to releases in 2007, 2009-2013, two feed treatments were allocated to raceways within adjacent raceway pairs. Fish from each raceway within the pairs were fed BioVita prior to smoltification, then the BioVita feed for one of the raceway pairs was supplemented with a BioTransfer diet and the other was not. The intent of the experiment was to determine whether the Transfer-supplemented-feed treatment increased the rate of smoltification, the nonsupplemented treatment serving as the control. Analyses indicated no significant or substantial differences between the supplemented and non-supplemented feed when averaged over years. See Appendix F of our 2019 annual report for additional detail.

## Control (Bio-Oregon) versus EWOS Feed Comparison (Brood Year 2006, Migration Year 2008)

This experimental design was similar to that described above for the Control versus saltwater transfer treatment study, with the standard Bio-Oregon pellets fed to half of the rearing ponds and an EWOS (www.ewos.com) diet fed to the other ponds. The different feed treatments only lasted about 6 weeks from the time of initial ponding as we found substantially higher mortalities for fish receiving the EWOS feed. From May 7, 2007 until these fish were released in 2008 all fish in this study received the Bio-Oregon diet. For the parameters of interest, we found no significant or substantial differences between the two feeding treatments (Appendix B of 2008 annual report).

## Smolt-to-Adult Survival

Calculation of smolt-to-adult survival rates for Yakima River spring Chinook is complicated by the following factors:

1) Downstream of the confluence of the Yakima and Naches rivers the three populations of spring Chinook (Upper Yakima, Naches, and American) are aggregated. A subsample of the aggregate wild/natural populations is PIT-tagged as part of the Chandler juvenile sampling operation but their origin is not known at the time of tagging. Through 2003, the primary purpose of this subsampling effort was to derive entrainment and canal survival estimates (see 2 below). Due to issues such as tag retention and population representation, adult detections of smolts PIT-tagged at Chandler cannot be used in any valid smolt-to-adult survival analyses.
2) Smolt accounting at Prosser is based on statistical expansion of Chandler smolt trap sampling data using available flow data and estimated Chandler entrainment rates. Chandler smolt passage estimates are prepared primarily for the purpose of comparing relative wild versus CESRF passage estimates and not for making survival comparisons. While these Chandler smolt passage estimates represent the best available data, there may be a relatively high degree of error associated with these estimates due to inherent complexities, assumptions, and uncertainties in the statistical expansion process. Therefore, these estimates are subject to revision. We are continuing to develop methods to subdivide the wild/natural outmigration into Upper Yakima, Naches, and American components based on DNA samples of juveniles taken at Chandler since 1998.
3) Installation of adult PIT detection equipment at all three ladders at Prosser Dam was not completed until the fall of 2005. Therefore, detection of upstream-migrating PIT-tagged adult spring Chinook at Prosser Dam was not possible for all returning fish until the spring of 2006. Periods of high flow may preclude use of automated detection gear so $100 \%$ detection of upstream migrants is not possible in all years.
4) Through 2006, detection of upstream-migrating PIT-tagged adult spring Chinook at Roza Dam occurred at an approximate $100 \%$ rate only for marked CESRF fish and wild/natural fish taken for broodstock. The majority of wild/natural fish were passed directly back to the river without PIT interrogation.
5) For the 1997 brood (1999 out-migration), 400 Khz PIT-tags were used. Mainstem detection facilities were not configured to detect these tags at nearly the efficiency that they can detect the newer 134.2 kHz ISO tags. Although all marked adult fish are trapped and hand-wanded for PIT detections of adults at Roza Dam, the reliability of the 400 kHz detection gear and problems with hand-sampling in general likely precluded a complete accounting of all 1997 brood PIT returns.
6) All CESRF fish are adipose-fin clipped and subjected to higher harvest rates than unmarked wild/natural fish in marine and Columbia River mark-selective fisheries. No adjustments have yet been made in the following tables to account for differential harvest rates in these mark-selective fisheries.
7) PIT tag retention is a factor in estimating survival rates (Knudsen et al. 2009). No attempt has been made to correct the data in the following tables for estimates of tag retention.
8) The ISAB has indicated that "more attention should be given to the apparent documentation that PIT-tagged fish do not survive as well as untagged fish. This point has major implications for all uses of PIT-tagged fish as surrogates for untagged fish." Our data appear to corroborate this point (Tables 45-46). However, these data are not corrected for tag loss. If a fish loses its PIT tag after detection upon leaving the acclimation site, but before it returns as an adult to Roza Dam, it would be included only as a release in Table 45 and only as an adult return in Table 46. Knudsen et al. (2009) found that smolt-to-adult return rates (SARS) based on observed PIT tag recoveries were significantly underestimated by an average of $25 \%$ and that after correcting for tag loss, SARS of PIT-tagged fish were still $10 \%$ lower than SARS of non-PIT-tagged fish. Thus, the data in Table 45 under-represent "true" SARS for PIT-tagged fish and SARS for PIT-tagged and non-PIT-tagged fish are likely closer than those reported in Tables 45 and 46.
9) Due to issues relating to water permitting, size required for tagging, and allowing sufficient time for acclimation, CESRF juveniles are not allowed to migrate until at least March 15 of their smolt year. However, juvenile sampling observations at Roza Dam indicate that a substantial number of wild/natural juveniles migrate downstream during the summer, fall, and winter months prior to their smolt outmigration year (Figure 7). Comparison of SAR data for non-contemporaneously migrating juveniles may be invalid (see Copeland et al. 2015).

Given these complicating factors, Tables 40-46 present available smolt-to-adult survival data for Yakima River CESRF and wild/natural spring Chinook. Unfortunately, true "apples-to-apples" comparisons of CESRF and wild/natural smolt-to-adult survival rates are not possible from these tables due to complexities noted above. The reader is cautioned to correct these data for, or acknowledge the factors noted above prior to any use of these data.

1. Mean flow (cfs) approaching Prosser Dam March 29-July 4 of juvenile migration year. No data available for migration year 1991. In high flow years (flows at or > 5000 cfs ) operation of the Chandler smolt sampling facility may be precluded during portions of the outmigration. Data courtesy of U.S. BOR hydromet.
2. Aggregate of Upper Yakima, Naches, and American wild/natural populations.
3. Estimated smolt-to-smolt (release from upper Yakima River acclimation sites to Chandler) survival for CESRF juveniles.
4. Includes combined age-3 through age-5 returns. CESRF adult returns and smolt-to-adult survival values are understated relative to wild/natural values since these figures are not adjusted for differential harvest rates in mark selective fisheries in marine and lower Columbia River fisheries.
5. Available data were not sufficient to estimate juvenile flow-entrainment and passage of wild/natural fish.
6. Data for most recent year are preliminary; return data do not include age-5 adult fish.

Table 40. Estimated wild/natural smolt-to-adult return rates (SAR) based on adult detections of PIT tagged fish. Roza tagged smolts to Bonneville Dam adult returns. Footnotes follow Table 42.

| 2015 | 1,783 | 2 | 2 |  | 4 | $0.22 \%$ |
| 2016 | 2,578 | 1 |  |  |  |  |

1. CESRF adult returns and smolt-to-adult survival values are understated relative to wild/natural values since these figures are not adjusted for differential harvest rates in mark selective fisheries in marine and lower Columbia River fisheries.
2. The reliability of the 400 kHz detection gear precluded an accurate accounting of all 1997 brood PIT returns. Therefore, this is not a true SAR. It is presented for relative within-year comparison only and should NOT be compared to SARs for other years.

Table 42. Overall wild/natural smolt-to-adult return rates (SAR) based on juvenile and adult detections of fish PIT-tagged and released at Roza Dam (Table B. 74 in McCann et al. 2019). McNary smolts to Bonneville Dam adult returns. For 2010 and 2014 migration years, few if any wild smolts were PIT-tagged at Roza.

1. When tag detection data are available, this is the number of unique PIT tags physically detected leaving the acclimation sites. Otherwise, this is the number of fish PIT tagged less documented mortalities of PIT-tagged fish from tagging to release.
2. BY1997 used 400 kHz tags and Bonneville Dam was not fully configured for adult detection of this type of tag; therefore we saw more detections at Roza Dam where fish were manually wanded for adult PIT detections.
3. Includes HxH fish beginning with this brood year.

Table 45. Estimated release-to-adult survival of non-PIT-tagged CESRF fish (CESRF tagged smolts to Roza Dam adult returns).

1. These fish were adipose fin-clipped, coded-wire tagged, and (beginning with 4 of 16 ponds in 1998) elastomer eye tagged. This is the number of fish physically counted at tagging.
2. BY1997 used 400 kHz tags and Bonneville Dam was not fully configured for adult detection of this type of tag; therefore we saw more detections at Roza Dam where fish were manually wanded for adult PIT detections.
3. Includes HxH fish beginning with this brood year.

## Harvest Monitoring

## Yakima Basin Fisheries

For spring fisheries in the Yakima River Basin, both the WDFW and the Yakama Nation employ two technicians and one biologist to monitor and evaluate in-basin harvest in the respective sport and tribal fisheries. Harvest monitoring consists of on-the-water surveys to collect catch data and to record tag information (e.g., elastomer, CWT, etc.) where possible for adipose-clipped fish. Survey data are expanded for time, area, and effort using standard methods to derive estimates of total in-basin harvest by fishery type (sport and tribal) and catch type (CESRF or wild denoted by adipose presence/absence).

Table 46. Spring Chinook harvest in the Yakima River Basin, 1985-present.

| Year | Tribal |  | Non-Tribal |  | River Totals |  |  | Harvest Rate ${ }^{1}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| Mean | 493 | 608 | 529 | 79 | 1,021 | 613 | 1,126 | 13.3\% |

1. Harvest rate is the total Yakima Basin harvest as a percentage of the Yakima River mouth run size.
2. Includes estimate of post-release mortality of unmarked fish.

Appendix B. Yakima River / CESRF Spring Chinook Salmon - Yakama Nation Data Summary 2019 Annual Report, May 29, 2020

## Columbia Basin Fisheries

Standard run reconstruction techniques are employed to derive estimates of harvest from the Columbia River mouth to the Yakima River mouth for spring Chinook. Data from databases maintained by the United States versus Oregon Technical Advisory Committee (TAC) are used to obtain harvest rate estimates downstream of the Yakima River for the aggregate Yakima River spring Chinook population and to estimate passage losses from Bonneville through McNary reservoirs. These data, combined with the Prosser Dam counts and estimated harvest below Prosser, are used to derive a Columbia River mouth run size estimate and Columbia River mainstem harvest estimate for Yakima spring Chinook.

Table 47. Estimated run size, harvest, and harvest rates of Yakima Basin spring Chinook in Columbia River mainstem and terminal area fisheries, 1986-present.

| Year | Columbia <br> R. Mouth <br> Run Size | Col. R. Mouth to BON Harvest | BON to <br> McNary <br> Harvest | Yakima <br> R. Mouth <br> Run Size | Yakima <br> River <br> Harvest | Columbia Basin Harvest Summary |  |  | Col. Basin Harvest Rate |  |

Appendix B. Yakima River / CESRF Spring Chinook Salmon - Yakama Nation Data Summary

## Marine Fisheries

Based on available CWT information, harvest managers have long assumed that Columbia River spring Chinook are not harvested in any abundance in marine fisheries as the timing of their ocean migration does not generally overlap either spatially or temporally with the occurrence of marine fisheries (TAC 1997). The Regional Mark Information System (RMIS) will be queried regularly for any CWT recoveries of CESRF releases in ocean or Columbia River mainstem fisheries. Table 49 gives the results of a query of the RMIS database run on Dec. 4, 2019 for CESRF spring Chinook CWTs released in brood years 1997-2014 and Figure 8 shows recovery locations for CWTs recovered in marine fisheries 2008-2012. Based on the information reported to RMIS to date, it is believed that marine harvest accounts for about $0-3 \%$ of the total harvest of Yakima Basin spring Chinook. The apparent increase for brood year 2013 may be attributable to a number of factors including: preliminary data or changes in fish distribution, ecological conditions, or sampling rates. CWT recovery data for brood year 2015 were considered too incomplete to report at this time.

Table 48. Marine and freshwater recoveries of CWTs from brood year 1997-2014 releases of spring Chinook from the CESRF as reported to the Regional Mark Information System (RMIS) 04 Dec, 2019.

| Brood | Observed CWT Recoveries |  |  | Expanded CWT Recoveries |  |  |
| :---: | ---: | ---: | ---: | ---: | ---: | ---: |
| Year | Marine | Fresh | Marine $\%$ | Marine | Fresh | Marine \% |
| 1997 | 5 | 56 | $8.2 \%$ | 8 | 321 | $2.4 \%$ |
| 1998 | 2 | 53 | $3.6 \%$ | 2 | 228 | $0.9 \%$ |
| 1999 |  | 2 | $0.0 \%$ |  | 9 | $0.0 \%$ |
| 2000 |  | 14 | $0.0 \%$ |  | 34 | $0.0 \%$ |
| 2001 |  | 1 | $0.0 \%$ |  | 1 | $0.0 \%$ |
| 2002 |  | 7 | $0.0 \%$ |  | 36 | $0.0 \%$ |
| 2003 |  | 4 | $0.0 \%$ |  | 10 | $0.0 \%$ |
| 2004 | 2 | 154 | $1.3 \%$ | 15 | 526 | $2.8 \%$ |
| 2005 | 2 | 96 | $2.0 \%$ | 2 | 304 | $0.7 \%$ |
| 2006 | 14 | 328 | $4.1 \%$ | 16 | 1160 | $1.4 \%$ |
| 2007 | 8 | 145 | $5.2 \%$ | 13 | 1139 | $1.1 \%$ |
| 2008 | 5 | 245 | $2.0 \%$ | 7 | 1634 | $0.4 \%$ |
| 2009 | 4 | 91 | $4.2 \%$ | 7 | 588 | $1.2 \%$ |
| 2010 | 4 | 164 | $2.4 \%$ | 9 | 948 | $0.9 \%$ |
| 2011 | 5 | 186 | $2.6 \%$ | 5 | 1030 | $0.5 \%$ |
| 2012 | 4 | 73 | $5.2 \%$ | 2 | 273 | $0.7 \%$ |
| 2013 | 9 | 65 | $12.2 \%$ | 20 | 534 | $3.6 \%$ |
| 2014 | 4 | 68 | $5.6 \%$ | 8 | 542 | $1.5 \%$ |

1. Reporting of CWT recoveries to the RMIS database typically lags actual fisheries by one to two years. Therefore, CWT recovery data for brood year 2014 are considered preliminary or incomplete.

Figure 9. Marine recovery locations of coded-wire-tagged CESRF spring Chinook, recovery years 2008-2012.

${ }^{1} \mathrm{BIO}=$ BioVita (BioOregon Protein Inc.) or control diet; STF = salt-water transition diet at acclimation sites. All fish are progeny of wild/natural parents unless denoted as HH which designates the hatchery control line beginning with brood year 2002. "Avg BKD" denotes the average BKD ELISA ranking of the female parents whose progeny were in these ponds.
${ }^{2}$ The number of fish released is estimated as the total number of fish counted at marking less mortalities documented from mark to release.

${ }^{1} \mathrm{BIO}=$ BioVita (BioOregon Protein Inc.) or control diet; STF = salt-water transition diet at acclimation sites. All fish are progeny of wild/natural parents unless denoted as HH which designates the hatchery control line beginning with brood year 2002. "Avg BKD" denotes the average BKD ELISA ranking of the female parents whose progeny were in these ponds.
${ }^{2}$ The number of fish released is estimated as the total number of fish counted at marking less mortalities documented from mark to release.

${ }^{1}$ All fish are progeny of wild/natural parents unless denoted as HC which designates the hatchery control line beginning with brood year 2002. "Avg BKD" denotes the average BKD ELISA ranking of the female parents whose progeny were in these ponds. PRO=BioPro diet, VIT=BioVita diet, Bio-Oregon products.
${ }^{2}$ The number of fish released is estimated as the total number of fish counted at marking less mortalities documented from mark to release.

## Executive Summary

Outmigrating smolts have been monitored since 1983 at the Chandler Diversion Canal in the Yakima River at Prosser, Washington. Chandler monitoring facility improvements over the years have made it possible to count all species entering the juvenile bypass system each year from January into July, encompassing the entire juvenile (smolts) out-migration period. Winter operations are made possible by the dual purpose of the canal, which supplies a hydroelectric plant as well as an irrigation district. The diversion is located downstream from all Spring Chinook, Summer Chinook, Coho and Steelhead spawning and juvenile rearing areas in the Yakima River Basin.

Numerous projects to restore and protect channel and riparian habitat, along with fish reintroduction programs have been implemented in the Yakima Basin since the 1990s. The population status and trends for the different species in their freshwater life stages are important measures of management success, and the data collected through the facility have allowed us to answer the several management questions that can help to improve/modify the programs. This report provides the estimation of last year's (2019) out-migrating smolt populations (hatchery and wild) of spring Chinook from Prosser; its temporal (annual) trend from 1999 through 2019; and evaluation of whether the production and releases of hatchery smolts into the upper Yakima had an effect on the production of wild smolts and on the relative frequency of the three stock sources of wild smolts (Naches, American, and Upper Yakima Rivers). This evaluation is part of an ongoing study that was initiated in 1999 with the first release of hatchery Spring Chinook smolts.

The entire bypass flow leaving the juvenile screens enters the counting facility but only a portion is manually counted. A timer gate on an hourly cycle directs bypass flow to a holding tank for a portion of each hour that can be adjusted as often as once per day to compensate for fluctuations in fish abundance so as to not overwhelm the capacity of the staff to tally those smolts by species and stock.

Last year (2019), the Chandler monitoring facility was in operation from January $13^{\text {th }}$ to July 4th (a total of 183 days), with occasional closures (5 days) due to high stream flows or bad weather condition. There were three gate timing settings (TR) for fish sampling. Over the 183 operating/sampling days, the timer gate setting (TR) was set at a $33 \%$ sample rate ( 20 minutes per hour) for 141 days, $\mathrm{TR}=50 \%$ for 5 days, and $\mathrm{TR}=100 \%$ for 32 days.

Several statistical methods/approaches were applied for expanding the subsample data and analyzing them. Most of the methods used in these analyses were based on the methods that were used in the previous year. To address the objectives of the study, we answered the following research questions.

## 1. How many species were captured during the sampling period and what are the relative

 abundances of the species?During the sampling period (January $13^{\text {th }}$ to July $4^{\text {th }}, 2019$ ) , 17 species were captured in the sampling room (trap). Among them, 9 species had counts totaling more than 100 individuals. Population of the Spring Chinook (hatchery and wild) had the highest count; whereas the lowest count was for the population of Dace species (Leuciscus leucisus) (only 3 counts), which was captured only in the month of March. Total counts (after adjustment) of the hatchery and wild spring Chinook that were trapped in the sampling facility during the sampling period were found to be 102,701 and 53,374 , respectively. Wild Spring Chinook smolts captured in the trap begun from the first sampling date and finished by the end of June, whereas hatchery Spring Chinook smolts begun only in March and gradually increased peaking in May, ending in June. Almost $36 \%$ of the total wild Spring Chinook smolts were trapped by the end of March; whereas during the same time period, hatchery Spring Chinook smolts were trapped at only $1 \%$ of yearly total. Last year, volitional releases of hatchery Spring Chinook from acclimation sites began March 14, indicating that only a few percent of the release arrived to the Prosser by the end of March.

## 2. What was the detection efficiency of the monitoring facility and did the efficiencies vary among the sampling periods (pre-March, March, April, May, Post-May)?

Based on the pooled data over the three Columbia River dams (PTAGIS juvenile detection sites MCJ, JDJ and B2J/BCC) downstream from the Yakima River, the detection rate of the monitoring facility at Prosser during the sampling period was $27.85 \pm 0.7 \%$ (mean $\pm$ SE), however it varied among sampling months. The highest detection rate occurred in May (39.63\%) as diversion rate increased with decreasing river flow.
3. How many wild and hatchery Spring Chinook smolts were estimated to pass Prosser Dam during 2019 and was there any temporal trend from the 1999 through 2019 juvenile migration years?

Wild (natural-origin) spring chinook can be separated genetically into three stocks: Upper Yakima, from the Yakima River and tributaries above the Naches River confluence; American River, a tributary of the Naches River; and Naches River, from the Naches River and tributaries exclusive of the American River. Only the Upper Yakima stock receives hatchery supplementation.

The estimated number of wild Spring Chinook smolts passing Prosser Dam during the 2019 migration period ranged from 154,530 to 175,427; whereas hatchery smolts ranged from 310,836 to 353,803. The estimated total number of hatchery Spring Chinook smolts passing Prosser Dam during the 2019 sampling period was almost double that of wild Spring Chinook smolts. On average over out-migration years $2000-2019,230,512 \pm 26,669$ wild and $322,470 \pm 16,547$ hatchery Spring Chinook smolts out-migrated or passed from Prosser. The total number of wild outmigrating smolts as well as its upper Yakima component stock seemed to be decreasing over time (from 2000-2019 out-migration year), whereas the population of Upper Yakima hatchery smolts seemed to be increasing; however these trends were not statistically significant.

## 4. What was the proportion of wild (Spring Chinook) populations that out-migrated from Prosser contributed by different stocks (Naches, American, Upper Yakima) in the Yakima Basin?

About $60 \%$ of the total count of wild out-migrating smolts at Prosser Dam was contributed by Upper Yakima stock; whereas $28 \%$ and $12 \%$ of the total out-migrating smolt populations were contributed by Naches and American river stocks, respectively. The result showed that the rate of decline in the wild Upper Yakima stock averaged -1184/year, which was the highest of the three wild populations (Naches, American, Upper Yakima), but the estimated decline was not significant (Upper Yakima; $\mathrm{R}^{2}=0.005, \mathrm{p}=0.76$ ). The rate of decrease for Naches stock was $-394 /$ year, it was also not significant; however, only the American stock average reduction was significant (Slope= $1087 /$ year, $\mathrm{R}^{2}=0.228, \mathrm{p}=0.04$ ). There was also an interaction between the proportions of wild stocks (Naches, American, Upper Yakima) in the out-migrating population and years ( $\mathrm{F}_{32,255}=3.67, \mathrm{p}<0.01$ ), indicating that the proportion of out-migrating population between the three stocks (Naches, Amrican and Upper Yakima) varied among migration years. For example, on average $60 \%$ of the total wild out-migrating smolts was contributed by Yakima stock, but when this percentage was lower in some years, the proportion of Naches stock became higher than average. The interaction might have occurred due to variation in the river conditions among the river basins in those years.

The upper Yakima River is more highly regulated by reservoir storage and releases than the Naches River, which may cause different population responses to annual flow variations.

## 5. Did the production and releases of hatchery smolts into the upper Yakima have an effect on the production of wild smolts (Naches, American, and Upper Yakima stocks)?

To evaluate if there was an effect of the hatchery program on wild production, we tested a hypothesis that the rate of decline of out-migration should be higher in the Upper Yakima's wild Spring Chinook, because only the Upper Yakima stock receives hatchery supplementation, but not in Naches and American river stocks. The result showed that there was no significant linear trend in the proportion of out-migrating smolt populations with the out-migration year for all three stocks (Upper Yakima, Naches, and American), indicating that there was no influence of hatchery supplementation on these out-migrating smolts at Prosser in the lower Yakima River. If a hatchery effect was present, the proportions of wild in Upper Yakima would have decreased significantly across the migration years.

## 6. What was the effect of river flow (daily as well as annual flow) on the number of outmigrating Spring Chinook smolt?

The annual juvenile Prosser passage estimate of wild and hatchery Spring Chinook tends to increase with the river flow approaching Prosser Dam, suggesting that higher river flow can help to push out the smolt populations from the river basin. When looking at the relationship between daily estimated counts and daily river flow (approaching the dam), the relationship was very strong (and significant) for the month of April, May and June but this relationship was not significant during pre-March and post-May. The results indicate on those days during the out-migrating period in which the river flow increased, the out-migration of smolts also increased.

## 1. Introduction

Conservation and management of culturally and economically important species rely on monitoring programs to provide accurate and robust estimates of population size. Numerous projects to restore and protect channel and riparian habitat have been implemented on the Yakima River in coordination with reintroduction/supplementation programs. Quantifying and understanding whether juvenile out-migration or Smolt-to-Adult-Return (SAR) are increased/decreased over time, or which stocks perform better, are fundamental questions in determining whether species management and production goals are being reached.

Outmigrating smolts have been monitored since 1983 at the Chandler Diversion Canal in the Yakima River at Prosser, Washington (Figures 2 and 3). The diversion is located downstream from all Spring Chinook, Summer Chinook, Coho and Steelhead spawning and juvenile rearing areas in the Yakima River Basin. The Chandler monitoring facility improvements over the years have made it possible to count all species entering the juvenile bypass system each year from January into July, encompassing the entire juvenile (smolts) out-migration period. Winter operations are made possible by the dual purpose of the canal, which supplies a hydroelectric plant as well as an irrigation district. Chandler Diversion canal typically conveys 1000 cfs with a maximum of 1500 cfs over the course of a year. Most of the portions of the water are used for irrigation and the remaining portion is returned to the Yakima River eleven miles downstream at the Chandler Powerhouse. The Yakima River at Prosser is characterized by a high spring runoff peaking in March, and low summer flows reaching a minimum in August however, there is a tremendous variation in this flow pattern and the timing of high or low flows among several years.

At the present Chandler Juvenile Monitoring Facility, fish are counted from the portion of the river flow that is diverted into the irrigation canal and then into the juvenile fish bypass system. The monitoring data collected at the facility from January into July every year can be useful to determine the status and trends of different species at the out-migrating smolt stage, identify potential life-cycle bottlenecks, and evaluate the effectiveness of ongoing reintroduction and habitat improvement actions on population dynamics. The number of smolts of different species that out-migrate from the river basin can be influenced by several environmental factors such as water temperature and river flows. River flow of the Yakima River is highly regulated and modified due to a number of large reservoirs in the Yakima basin that have been developed to store water during the high flow
season and release water as required for irrigation and maintenance of ecological processes during summer months. River flows vary by year and day-by-day within a season. Reducing the river flow during the fish outmigration period can be detrimental to juvenile survival and the rate of outmigration. Several studies showed that peak flows can cue fish to out-migrate so that river flow pulses (higher temporal variability of river flow) can provide a greater opportunity for smolt movement downstream and to survival to the ocean. Relying entirely on annual totals may obscure how out-migrating smolt populations are affected by river flow in the Yakima Basin.

The main objectives of the study were to estimate prior-year (2019) out-migrating smolt populations (hatchery and wild) of spring Chinook; assess its temporal trend from 1999 through 2019; determine whether the production and releases of hatchery smolts into the upper Yakima had an effect on the production of wild smolts and on the relative abundances of the three stock sources of wild smolts (Naches, American, and Upper Yakima Rivers); and evaluate whether out-migration is higher in the years that had high river flow; as well as higher smolt out-migration on days in which river flow was higher. To address the objectives, we answered the following research questions:

- How many species were captured during the 2019 sampling period and what are the relative abundances of the species?
- What was the detection efficiency of the monitoring facility, and did the efficiencies vary among the sampling periods (pre-March, March, April, May, Post-May) in 2019?
- How many wild and hatchery Spring Chinook smolts emigrated from Prosser during 2019 and was there any temporal trend from 1999 through the 2019 juvenile migration year?
- What was the proportion of wild Spring Chinook populations that out-migrated from Prosser contributed by different stocks (Naches, American, Upper Yakima) in the Yakima Basin? Do the proportions of these stocks in the out-migrating smolt population vary by migration years?
- Did the production and release of hatchery smolts into the upper Yakima have an effect on the production of wild smolts (Naches, American, and Upper Yakima Rivers)?
- What was the effect of river flow (daily as well as annual flow) on the number of outmigrating Spring Chinook smolts?

### 2.0 Methodology

The Chandler juvenile monitoring facility is located on the fish bypass outlet of Chandler Canal at Prosser Dam (Figures 2 and 3), which is about 76 river km ( 47 river miles) upstream from the mouth of the Yakima River. This Canal is basically used to supply water for irrigation and to generate power. The Chandler Canal typically conveys 1000 cfs with a maximum of 1500 cfs over the course of a year (Pyper and Smith, 2005). However only the portion of the river flow that has been diverted into the irrigation canal enters the bypass system. Similarly, the entire bypass flow leaving the juvenile screens enters the counting facility but only a portion is manually counted. A timer gate on an hourly cycle directs bypass flow to a holding tank for a portion of each hour that can be adjusted as often as once per day to compensate for fluctuations in fish abundance so as to not overwhelm the capacity of the staff to tally those smolts by species and stock. For this study, several methods were used and are outlined in Fig. 1.

Figure 1. Outline of the methodology used for data analysis in this report

Figure 2. Yakima basin and the location of the Chandler juvenile facility at Prosser and different sub-basins or genetic stocks (Naches, Upper Yakima River and American River).

### 2.1. Estimating Sample Rate and Calibration

Figure 3 shows the Chandler Monitoring facility's layout and the details of the sampling area. Sampling period was from January $9^{\text {th }}$ to July $6^{\text {th }}$ in 2019 except a few days in which the facility was shut down due to adverse weather conditions. Timer gate settings (TR) varied over days based on the number of the sampled smolts entering the counting facility so as to not overwhelm the capacity of the facility or the ability of the staff to tally those smolts by species and stock.

In 2019, there were three time gate settings, $\mathrm{TR}=33 \%$ ( 20 minutes per hour), $\mathrm{TR}=50 \%$ ( 30 minutes per hour), and $\mathrm{TR}=100 \%$. The timer gate directs the bypass flow into the counting facility for a set percentage of each hour. That percentage, referred to herein as the timer-gate rate (TR), the
timer gate often changes between sampling days during the sampling period to accommodate the capability of staff to manage and tally the number of smolts. There are two PIT-tag detectors (Figure 3): one in the bypass upstream of the timer gate and one in the exit from the counting facility downstream of the timer gate where a set proportion of the smolts are tallied. Along with detectors in the Prosser adult ladders, these detectors comprise site PRO in the PIT Tag Information System (PTAGIS) maintained by the Pacific States Marine Fisheries Commission.

Figure 3. Site Overview of Chandler Juvenile Monitoring Facility at Prosser. The layout was adapted from the site configuration at https://www.ptagis.org/.

The timer gate, when opened, directs the Prosser bypass flow from Chandler Canal into the monitoring facility in which smolts are tallied. Data regarding species, its life stage, and abundance were tallied and counted daily during the sampling period. For a given daily TR-setting, the sample rate was computed as
$\mathrm{SR}_{\mathrm{t}}: \frac{\text { the number of PIT-tagged Spring Chinook smolts detected in the counting facility }}{\text { the total number detected by a bypass detector located upstream of the timer gate }\left(T G_{i}\right)}$; or
$\mathrm{SR}_{\mathrm{ti}}=\frac{\mathrm{n}[\text { counting facility }] /}{\mathrm{n}[\text { bypass }(\mathrm{TR})]}$; Where $t i$ is the timer setting.
Once we estimated the daily sample rate, the calibration value was computed as:

$$
\text { Calibration value }(\mathrm{CV})=\mathrm{w}(33 \%) *[\operatorname{SR}(\mathrm{TR}=33 \%) / 33 \%]+\mathrm{w}(50 \%) *[\operatorname{SR}(\mathrm{TR}=50 \%) / 50 \%]
$$

Where $\mathrm{w}(33 \%)$ and $\mathrm{w}(50 \%)$ are the weight, which are the proportion of bypass detections within the TR setting 0.33 and 0.50 , respectively. The weights being the proportions of bypass detections within the TR setting and estimated as (see, Neeley 2012):

$$
\begin{aligned}
& \mathrm{w}(33) \%=\mathrm{n}[\operatorname{bypass}(\mathrm{TR}=33 \%)] /\{\mathrm{n}[\operatorname{bypass}(\mathrm{TR}=33 \%)]+\mathrm{n}[\operatorname{bypass}(\mathrm{TR}=50 \%)]\} \\
& \mathrm{w}(50) \%=\mathrm{n}[\operatorname{bypass}(\mathrm{TR}=50 \%)] /\{\mathrm{n}[\operatorname{bypass}(\mathrm{TR}=33 \%)]+\mathrm{n}[\operatorname{bypass}(\mathrm{TR}=50 \%)]\}
\end{aligned}
$$

### 2.2. Missing data imputation

On a daily basis, fish were counted and tallied as to source (hatchery-spawned or wild). However, the sampling facility was shut down for a few days due to flow conditions or other technical problems. Data are missing for those days in which the sampling facility was closed. Linear interpolation was used to impute values (fill in data) for the missing information.

### 2.3. PIT tagged data

We queried the PTAGIS database (https://www.ptagis.org/) in April 2020 to retrieve available PITtag detection information for all Spring Chinook Salmon smolts (hatchery) released upstream of the Prosser Dam. A total of 42,542 smolts were used for this analysis and an encounter history for each fish with detection events (date and Dams) was constructed for further analysis.

### 2.4. Genetic information

During the sampling period each year, tissue samples were taken from the subsamples of wild smolts passing through the counting facility. In order to minimize bias, samples of smolts were distributed proportionally among five time strata (January-Feb., March, April, May and June). These tissue samples were processed in the Molecular Genetics Laboratory of the Washington Department of Fish and Wildlife (WDFW). Results of 2018 molecular samples are available (see, Seamons and Bowman, 2019) and this information was used to estimate 2018 out-migrating smolts; results of 2019 genetic data are not yet available.

### 2.5. Estimating Prosser bypass detection efficiencies

The proportions of all PIT- tagged smolts released above Prosser and detected at mid-Columbia dams that were previously detected in the Chandler Canal bypass serve as estimates of bypassdetection efficiency. Three downstream detection sites were used to estimate Prosser Bypass's detection efficiency—McNary, John Day, and Bonneville Dams—and detections were pooled over the three dams. A given downstream dam's daily Prosser bypass detection efficiency is unlikely to be homogeneous over days because the river flows and spill rates often vary and the detections are from a mixture of daily passages. Therefore for each downstream dam the detection efficiencies are stratified over the downstream passage time (pre-March, March, April, May and post-May) based on only McNary Dam or pooled over the three Columbia Dams (McNary, John Day and Bonneville Dams). The detection efficiency was estimated as:
$\mathrm{DE}=\mathrm{n}$ (daily joint site detections) $/ \mathrm{n}$ (total site detections)

These detection efficiencies based on hatchery Spring Chinook were applied to both populations coming from the hatchery and wild sources. The wild stocks were tallied smolts that were not coded-wire tagged. The wild Spring Chinook were made up of Naches, American, and UpperYakima stock (See fig. 1). All and only hatchery smolts were coded-wire tagged and were of Upper Yakima stock. Most hatchery smolts were also elastomer tagged by acclimation site. Acclimation sites included Clark Flat, Easton, and Jack Creek, respectively receiving red, green, and orange elastomer tags. These tags were also tallied and pooled. The hatchery smolts that were not elastomer-tagged were PIT-tagged prior to release.

The wild and elastomer-tagged hatchery tallies were expanded by four different estimates of Prosser detection rates as mentioned above.

1. McNary-based un-stratified detection rate estimate
2. McNary-based stratified detection rate estimate
3. Pooled-lower-dam-based un-stratified detection rate estimate
4. Pooled-lower-dam-based stratified detection rate estimate

Detailed methodology is given in Neeley (2019; appendix C).

In summary, four estimators were used, and the one chosen was a pooling of stratified estimates from the detection efficiencies from McNary, John Day, and Bonneville Dams on the Columbia Rivers; the strata being established for each of these dams by combining daily estimates that were deemed similar using Logistic stepwise regression of the daily detection efficiencies on Julian-date indicators that take the value 1 if the estimate was from a given date or a later date or 0 if the estimate was from an earlier date.

### 2.6. Wild and hatchery passage estimate

On a daily basis the sampled Spring Chinook smolts were tallied as to source (hatchery-spawned or wild). On those days when the facility was shut down, linear interpolation was used to impute values to the missing information as mentioned above. The daily actual and imputed tallies were divided by the sample rates in use on those days (SR). The sample-rate-adjusted tallies for each source were added over days within each of five time periods and were then divided by the respective period's detection efficiencies. The wild and hatchery smolts were tallied separately. The wild smolts were identified by the lack of a coded-wire tag. The hatchery smolts were identified by the presence of an elastomer tag and adipose fin clipped and absence of coded-wire tag. Expanded elastomer-tagged tallies were then divided by the proportion of hatchery smolts to obtain estimates of the passage of all hatchery smolts.

Within five time periods (pre-March, March, April, May, post-May), the tallied sample wild smolts were subsampled and genetically classified as to brood origin (stock from the American, Naches, or Upper Yakima Rivers). Within each period, the brood-origin proportions of those sampled smolts were computed by WDFW. The wild passage estimates within each period were multiplied by each of the period's brood-source proportions. Each brood's time-period wild passage estimates were then added over the time periods to estimate the brood's total passages as were the hatchery passage estimates. The detailed methodology can be found in Neeley, (2019).

### 2.7. Model validation (estimates comparisons)

The estimates of the number of smolts passing Prosser Dam can vary with different methods that are used in the analysis. To ascertain which of the passage estimates is the best to report and use for further analysis, we compared these estimated populations at Prosser of hatchery Spring Chinook smolts to another estimate that was derived using its survival rate (release site to Prosser). Since we know the total released number of hatchery Spring Chinook smolts in the upper Yakima, we
multiplied the survival rate by the total released populations, which provide us the total smolt populations passing at Prosser. This estimate can be viewed as an independent estimate for the comparison, however this estimate can also be biased because the survival rate seemed to be heterogeneous over days but here we assumed there was no variation in the survival rate among the sampling days. If detection efficiency is not homogeneous, survival rate cannot be homogeneous. However, this value can be an additional reference to cross check even if it is not perfect data to compare.

In addition to the above method, each of the other four methods' estimates of hatchery juvenile passage (see above section 2.5) was also compared with hatchery returns. If the estimate is a reasonable value it should be highly correlated with the predicted hatchery adult returns.

### 2.8. Estimated Daily smolt out-migration from Prosser

One of our objectives was to determine whether river flows influence the size of the population of out-migrating smolts If larger number of smolts out-migrated during high river flow, the rate of outmigration would be a function of river flow. To estimate daily passage at Prosser Dam, daily counts of each species in the live box at the Chandler Juvenile Monitoring Facility (CJMF) were expanded by the canal entrainment, canal survival (from prior paired releases), and sub-sampling rates using the following formula (Neeley, 2012).

Entrainment rate $(E R)=1 / 1+\exp (-5.60081+13.5861 *$ diversion rate $)$

Estimated daily count: Count/(Survival Probability * sample. rate(SR) * ER)

The model for the ER was based on the logistic regression using the daily proportion of Yakima River flow diverted into the canal. The Entrainment Rate (ER) is the predicted daily proportion of fish passing Prosser that are entrained into Chandler Canal, the Canal-Survival Rate (Survival probability) is the daily predicted proportion of those entrained fish that survive the canal from below the head-gate down the canal and into the bypass to a point just above the sampling station, and Sampling Rate (SR) is the estimated proportion of fish that are sampled from the bypass and enumerated.
2.8.1. Relationship between river flow and estimated daily count

To determine whether high river flow helped to increase the rate of smolt out-migration from Prosser, we built univariate relationships using two datasets (annual and daily).
A. Annual total estimates: A univariate linear relationship between the estimated total annual number of hatchery Spring Chinook smolts passing Prosser (2000-2019 out-migration years) and the average river flows (average of four months [March-June]) for each year for 20002019. We chose the average of only four months because the hatchery juvenile/smolts exited from the acclimation sites from March to June.
B. Daily estimates: A univariate linear relationship between the estimated daily count of wild Spring Chinook and daily river flow. River flow is considered as flow that approaches the dam, and sum of the flow measured at the gauge stations CHCW and YRPW. River flow data were accessed in April, 2020 from
https://www.usbr.gov/pn/hydromet/yakima/yakwebarcread.html.

### 3.0 Results and discussion

In 2019 the Chandler monitoring facility was operated from January $13^{\text {th }}$ to July $4^{\text {th }}$ ( 183 days total), with occasional closures (5 days) due to excessively high stream flows or other problems. There were three timer gate settings (TR) for sampling. Among the 183 days, the timer gate setting (TR) was $33 \%$ for 141 days, $\mathrm{TR}=50 \%$ for 5 days, and $\mathrm{TR}=100 \%$ for 32 days. In 2019 the results showed that when TR was $33 \%$, sample rate (SR) was $29.9 \%$ (see Table 1). In almost all cases, the SR was less than the TR, indicating not all fish passing through the bypass when the timer gate was open are actually entering and being detected in the counting facility.

Table 1. Sample-room sample rates for given timer-gate settings. Timer Gate Rate (TR) is the proportion of time that the bypass gate is opened to Sample Room.

| Out- <br> Migrati on Year | Calibrati on Value | Estimated Sample Rates (SR) for different Timer-Gate Rates |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Timer-Gate Rate (TR) |  |  |  |  |  |  |  |  |

Note: Estimates for the year1998-2018 were adopted from Neeley (2019)

### 3.1. Species composition and daily counts in the counting facility

During the sampling period, altogether 17 species were captured in the sampling room (trap).
Among them, 9 species (Smallmouth bass, Channel catfish, Chiselmouth, Coho, Lamprey, Spring Chinook, Steelhead, Sucker and Whitefish) had counts more than 100 individuals (see Figure 4). Spring Chinook (hatchery and wild) had the highest count (43,034, before adjusted) and the second highest count was Coho $(24,823)$ during the sampling period. The population of Dace (Rbinichthys sp.) had the lowest count (only 3 counts, see Fig. 4), which was captured only in March. Among the sampling periods (pre-March, March, April, May, post-May), almost $67 \%$ of the total counts were in May, whereas $15 \%$ in April, $9 \%$ in post-May, $4 \%$ in March and also 4\% in pre-March.

Adjusted total counts of the hatchery and wild spring Chinook during the sampling period were estimated to be 102,701 and 53,374 , respectively (see table 2, Figure 5A). Wild Spring Chinook smolts captured in the trap since the beginning of sampling and ended in end of June; whereas hatchery Spring Chinook smolts captured in the trap begun only in March, gradually increased and peaked in May, ending in June. Almost $36 \%$ of the total wild Spring Chinook smolts were trapped by the end of March; whereas during that time only $1 \%$ of hatchery Spring Chinook smolt were trapped (Figure 5B and C). It seems that the wild spring Chinook start to out-migrate earlier than the hatchery Spring Chinook, however the volitional releases are normally allowed beginning on or shortly before March 15th (as early as March 9th) and remaining fish are forced out of the acclimation sites no later than May 16th each year from the acclimation sites (Clark Flat (CFJ), Jack Creek (JCJ) and Easton (ESJ)).

Figure 4: Daily catch of different species from January through July, 2019 (sampling period). Number in green color is the total counts in the sampled during the sampling period.

Table 2. Adjusted total count of hatchery and wild Spring Chinook smolts in the monitoring facility (CJMF) during the sampling period of 2019 and among the strata (Pre-March, March, April, May and Post-May).

| Origin | Adjusted counts |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Pre-March | March | April | May | Post-May | Total |
| Wild | 15489 | 3937 | 10596 | 23290 | 63 | 53374 |
| Hatchery | 0 | 904 | 24775 | 76824 | 198 | 102701 |

Figure 5. Daily counts (Adjusted counts) of wild and hatchery Spring Chinook in the trap (counting facility) from January through July 2019 [A]; percentage of the catch by sampling period stratum [B]; and cumulative catch proportion (January to June, 2019; [C]).

### 3.2. Detection efficiencies of sampling facility

In 2019 approximately $6 \%$ of the total released juveniles (hatchery Spring Chinook smolts) were PIT-tagged and released from the acclimation sites (Clark Flat, Jack Creek and Easton). Using exit detections instead of tagging data eliminates mortalities and shed tags from release counts, but tag collisions when too many fish pass detectors at once can result in undercounting releases, although such detection failures have amounted to a few percent at most. In total, tagged earlier as well as
including untagged hatchery outmigrants captured and tagged at Roza Dam for downstream survival studies, 42,542 PIT tagged hatchery Spring Chinook were used for further analyses.
Among the PIT-tagged hatchery Spring Chinook, 5,858 were detected at the sampling facility in Prosser in 2019. The number of tagged fish detected at Prosser that were also detected at downstream dams depended on downstream detection probability in addition to downstream mortality. Joint detections between Prosser (PRO) and McNary (MCJ), PRO and John Day (JDJ); and PRO and Bonneville Dam (B2J/BCC) were found to be 369, 320, and 465, [1154 total], respectively for the 2019 released smolts (hatchery Spring Chinook).

The average detection rate of the sampling based on PRO and JDJ joint-detection (when taking the detection of Prosser with reference of JDJ) was relatively high ( $29.46 \pm 1.4 \%$; mean $\pm$ SE) compared to the based on Prosser and B2J/BCC (27.04\%) (see, Table 3). Based on the pooled over the three Columbia Dams (MCJ, JDJ and B2J/BCC), the detection rate of the monitoring facility of Prosser during the sampling period was $27.85 \pm 0.7 \%$ (mean $\pm \mathrm{SE}$ ). The joint detection rate also varied by strata. The highest detection rate was in May (39.63\%); whereas the lowest was in PreMarch (0\%) for hatchery Spring Chinook smolt.

Table 3. Detection efficiencies of Prosser (PRO) and joint detection of the smolts of the hatchery Spring Chinook between PRO and McNary (MCJ), PRO and John Day (JDJ), PRO and Bonneville (B2J/BCC); and PRO and the detection at all dams (Pooled). Detection of Bonneville included the juvenile (smolt) population of hatchery Spring Chinook detected by B2J, BCC antennas.

| Joint detection <br> bet $^{\mathrm{n}}$ | Months |  |  |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Pre- <br> March | March | April | May | Post- <br> May | Joint | detection $\pm$ SE |

Table 4. Detection at Prosser based on strata (Un-stratified and Stratified) with the reference of McNary Dam and pooled over the three Columbia River dams (MCJ, JDJ and B2J/BCC). Rate of Redistribution was estimated by pooling the five time periods into two groups: pre-March through April, and May through Post-May.

| Reference | Strata | Pre- <br> March | March | April | May | Post-May |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Based on MCJ | - Un-stratified | 27.61\% | 27.61\% | 27.61\% | 27.61\% | 27.61\% |
|  | - Stratified | 0.00\% | 19.38\% | 17.72\% | 35.63\% | 0.00\% |
|  | - Stratified <br> (Redistributed) | 18.47\% | 18.47\% | 18.47\% | 35.63\% | 35.63\% |
| Based on pooled Dams (MCJ, JDJ \& B2J/BCC) | - Un-stratified | 27.93\% | 27.93\% | 27.93\% | 27.93\% | 27.93\% |
|  | - Stratified | 0.00\% | 24.64\% | 20.27\% | 36.13\% | 0.00\% |
|  | - Stratified |  |  |  |  |  |
|  | (Redistributed) | 20.07\% | 20.07\% | 20.06\% | 35.88\% | 35.88\% |

### 3.3. Predicted number of out-migrating wild and hatchery Spring Chinook smolts

The total number of hatchery Spring Chinook smolts (Juvenile Prosser-passage estimates) passing at Prosser during the 2019's sampling period was almost double that of the Wild Spring Chinook smolts (Table 5). Based on the different methods that were used to estimate the detection rate at Prosser, the estimates of wild Spring Chinook smolts passing Prosser Dam also varied and ranged from 154,530 to 175,427 ; whereas the hatchery smolt estimates ranged from 310,836 to 353,803 . The estimates based on different estimators from 1999-2019 are given in the supplementary document (see attached Supplementary document A).

Table 5. The estimated number of wild and hatchery Spring Chinook smolts migrating past Prosser Dam during 2019 using four estimators (methods).

|  | Estimates |  |
| :--- | :--- | :--- |
| Estimators (Methods) | Wild | Hatchery |
| MCJ_Unstratified | 168,119 | 310,836 |
| MCJ_Stratified (redistributed) | 154,848 | 353,803 |
| Pooled_Unstratified | 175,427 | 319,579 |
| Pooled-Stratified (redistributed) | 154,530 | 343,212 |

Among the four estimates, choosing which estimate was the best was challenging. We further compared these estimates with another independent estimate derived by another method that was based on its survival rate. The average survival rate from the release sites to Prosser during the
sampling period was $50.82 \pm 2.2 \%$ (based on CJS model) and the total number of released hatchery Spring Chinook smolts during 2019 was 673,218 . Using the survival rate and released population, the total out-migration of hatchery Spring Chinook from Prosser would be 342,129 $\pm 14,810$ (mean $\pm$ SE). This estimate seemed to be compatible with the estimate derived from the pooled stratified (redistributed) method. However the estimates based on survival rate may still have some bias because the survival rate may not be homogeneous among the sampling months, especially due to variation of river flow at Prosser within the sampling period. However, previous years' analyses also showed that estimate based on pooled-lower-dam-based stratified detection rate (method 4) was highly correlated with hatchery returns.

### 3.4. Annual trend of juvenile Prosser-passage estimates (hatchery and wild) by stock

Annual juvenile Prosser-passage estimates from out-migration years 1999 through 2019 are given in Table 6 by stock of wild origin (Naches, American, and Upper Yakima Rivers) plus hatchery Upper Yakima River origin. It showed that Prosser juvenile estimates for both wild and hatchery vary among the out-migration year. In an average year, $230,512 \pm 26,669$ wild and $322,470 \pm 16,547$ hatchery Spring Chinook smolt out-migrated from Prosser (Table 6 and Figure 6). Wild Spring Chinook from the American River had the lowest average, Naches had the second,, and Upper Yakima subbasin had the highest average among the wild stocks (Figure 6). Total Spring Chinook out-migration per year was $552,982 \pm 30,492$. The number of out-migration of both wild and hatchery juvenile from Prosser during 2019 was relatively higher than the smolt out-migrated during 2018 out-migration year (Table 6).

Table 6: Annual estimated wild and hatchery-origin smolt passage at Prosser Dam from the 1999 through 2019 out-migration years.

| Brood Year (BY) | Outmigration Year | Wild Stock Estimates |  |  |  | Hatchery (Upper Yakima) | Total Wild \& Hatchery |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Total Wild | Naches | American | Upper <br> Yakima |  |  |

| 2016 | 2018 | 131,489 | 37,500 | 9,824 | 76,150 | 290,644 | 422,133 |
| 2017 | 2019 | 175,427 | Genetic samples not yet available |  |  | 319,579 | 495,006 |
| Average/year |  | 230,512 | 62,174 | 25,678 | 146,854 | 322,470 | 552,982 |
| Standard Error (SE) |  | 26,669 | 6,309 | 3,450 | 24,230 | 16,547 | 30,492 |

Estimates for the out-migration years from 1998 through 2018 were adopted from Neeley 2019 (Appendix C in Fiander et al. 2019).

Figure 6. Average annual Prosser-passage estimates (2000-2019; out-migration years) of wild and hatchery Spring Chinook by stock. Dot with red color is the mean and central line is the median. The out-migration year 1999 was not included for this box plots because in that year, only a few raceways were used for hatchery production compared to other years. Similarly, 1999 was the last outmigration year in which the old "ISO" tags with poor read range were used.

Although the out-migration populations of all three stocks (Total wild, Upper Yakima wild, and Upper Yakima hatchery) varied by out-migration year, we further estimated its linear trend over outmigration years and compared among stocks. In 1999, only 14 of 18 raceways were used for hatchery production. As a result, the Prosser passage estimates for hatchery smolts in 1999 seemed to be very low, which might not be compatible with other years' hatchery estimates. Brood year1997 (Migration Year 1999) had 10 raceways in use; Brood year 1998 (migration Year 2000) had 16 raceways in use; Brood year 2001 (Migration Year 2003) had 10 raceways in use with an 11 ${ }^{\text {th }}$ raceway's $\sim 40,000$ fish split among 6 raceways (to approximate the densities in other production raceways). Therefore, two relationships were developed using the data with and without 1999's passage estimates for all three stocks (total wild, Upper Yakima wild, and Upper Yakima hatchery). In both datasets, the total number of out-migrating wild smolts and the number of wild upper Yakima smolts seemed to be decreasing over time, whereas the population of Upper Yakima hatchery smolts seemed to be increasing; however these trends were not statistically significant [Figure 7 upper panel A1,B1 and C1- total Wild: slope $=-1184, \mathrm{R}^{2}=0.006 ; \mathrm{p}=0.76$; Wild upper

Yakima: slope $=-1956, \mathrm{R}^{2}=0.015 ; \mathrm{p}=0.605 ; ;$ Hatchery Upper Yakima: slope $=4140, \mathrm{R}^{2}=0.119$; $\mathrm{p}=0.137]$.

Figure 7. Estimated Juvenile Prosser-Passage populations of total wild, Upper Yakima wild, and Upper Yakima hatchery stocks with predicted trends by out-migration year. A1, B1, and C1 are for out-migration years 2000-2019 (omitting 1999 data); whereas A2, B2, and C2 were created using all out-migration years from 1999 through 2019.

Although out-migration of hatchery smolts of Upper Yakima is increasing but not significantly so, there was a possibility that a true positive increase in hatchery smolt passage coming from the Upper Yakima would have an associated true negative decrease in wild passage. Therefore, the assessment of wild and hatchery trends was further examined using the percentage changes in out-migrating smolt populations of wild and hatchery over years (hatchery plus wild).

Table 7. Percentage of wild (including American, Naches, and Upper Yakima) and hatchery (only upper Yakima) stocks in juvenile Prosser passage estimates.

| Brood Year (BY) | Outmigration Year | Total Yakima Basin |  | Only Upper Yakima River |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | \% <br> Hatchery of Total | \% Wild of Total | \% Hatchery of Upper Yakima Stock | \% Wild of Upper Yakima stock |
| 1997 | 1999 | 24.32\% | 75.68\% | 30.50\% | 69.50\% |
| 1998 | 2000 | 60.36\% | 39.64\% | 76.60\% | 23.40\% |
| 1999 | 2001 | 65.45\% | 34.55\% | Genetic sam | es not taken |
| 2000 | 2002 | 43.98\% | 56.02\% | 50.67\% | 49.33\% |
| 2001 | 2003 | 33.31\% | 66.69\% | 44.61\% | 55.39\% |
| 2002 | 2004 | 63.20\% | 36.80\% | 79.81\% | 20.19\% |
| 2003 | 2005 | 63.68\% | 36.32\% | 97.78\% | 2.22\% |
| 2004 | 2006 | 69.28\% | 30.72\% | 79.94\% | 20.06\% |
| 2005 | 2007 | 77.96\% | 22.04\% | 85.09\% | 14.91\% |
| 2006 | 2008 | 68.87\% | 31.13\% | 76.71\% | 23.29\% |
| 2007 | 2009 | 63.68\% | 36.32\% | 76.33\% | 23.67\% |
| 2008 | 2010 | 63.41\% | 36.59\% | 77.18\% | 22.82\% |
| 2009 | 2011 | 59.25\% | 40.75\% | 66.04\% | 33.96\% |
| 2010 | 2012 | 60.26\% | 39.74\% | 71.90\% | 28.10\% |
| 2011 | 2013 | 50.45\% | 49.55\% | 59.41\% | 40.59\% |
| 2012 | 2014 | 60.79\% | 39.21\% | 72.45\% | 27.55\% |
| 2013 | 2015 | 72.67\% | 27.33\% | 80.33\% | 19.67\% |
| 2014 | 2016 | 68.54\% | 31.46\% | 78.23\% | 21.77\% |
| 2015 | 2017 | 56.67\% | 43.33\% | 69.08\% | 30.92\% |
| 2016 | 2018 | 68.85\% | 31.15\% | 79.24\% | 20.76\% |
| 2017 | 2019 | 64.56\% | 35.44\% | Not yet Available |  |

Note: Estimates for the out-migration years from 1998 through 2018 were adopted from Neeley (2019).

The results showed that rate of change over years for both hatchery and wild groups seemed to be positive (Figure 8) but still it was not statistically significant. It indicates that the production and releases of hatchery smolts into the upper Yakima had no effect on the production of wild smolts.

Figure 8. Linear trend on the percentage of hatchery and wild components of the total out-migrating populations by out-migration year (2000-2019). For the Upper Yakima trend analysis (right), the 2019 estimate was not used because genetic analysis for the stock assignment was not yet available).

### 3.5. Genetic variations among the stocks (Upper Yakima, Naches, American)

As mentioned above, the wild Spring Chinook in the Yakima Basin are composed of multiple stocks including Upper Yakima River, Naches River, and American River among others. The reproductively isolated populations usually differ in productivity and capacity. We, therefore, further evaluated whether the rate of out-migration of these genetic stocks has changed over time. This analysis can also test a hypothesis if there was an effect of the hatchery program on wild production. If there is an effect of hatchery on wild production, we can also expect a high degree of decline in the wild smolt out-migration population from the Upper Yakima compared to the American and Naches River out-migrants because no hatchery program has been implemented in the American and Naches rivers. We, therefore, hypothesized that the rate of decline should be higher in the Upper Yakima's wild Spring Chinook, if there was an effect of the hatchery program. The result showed that the wild Spring Chinook smolt population declined over the2000-2019 out-migration years (Figure 9) for all three stocks. The rate of decline in the Wild Upper Yakima stock was -

1184/year, which was the highest of the three wild, but the estimate was not significantly different $\left(\mathrm{r}^{2}=0.005, \mathrm{p}=0.76\right)$. The rate of decline for the Naches River stock was $-394 /$ year, it was also not significant. Only the American stock average reduction was significant (Slope= -1087/year, $R 2=0.228, p=0.04$, Figure 9); there has been no introduction of hatchery smolts into the American River. The American River seems to have a relatively low anthropogenic effect compared to other rivers. It is also coldest and has entirely natural flow that persists through the summer. The Juveniles probably grow the slowest and may be the smallest at outmigration. One can speculate that if ocean conditions are worsening, the fish that spend more time there are affected more, but relating this to population decline. Similarly, earlier studies (Zabel and Achord 2004; and Zabel et al. 2005) found that juvenile survival rate of wild salmonids was related to fish size (fork length), with larger juveniles having higher downstream survival. These factors may have played a role in declining the survival rate.

Figure 9. The relationship between the estimated out-migration populations of Naches, American, and Upper Yakima by out-migration year.

About $60 \%$ of the total wild out-migrating smolts from Prosser was contributed by the Upper Yakima wild stock; whereas $28 \%$ and $12 \%$ of the total population were contributed by Naches and American River stocks, respectively (Table 8 and Figure 10). There was no significant linear trend in
the wild proportion by out-migration year for any of the three stocks (Upper Yakima, Naches, and American), indicating that there was no hatchery effect on out-migrating smolts sampled at Prosser Dam. If the hatchery effect was present, the proportion of wild Spring Chinook in the Upper Yakima would have decreased over migration years.

Table 8. American, Naches and Upper Yakima Percentages of Prosser passage of wild Spring Chinook smolts at Prosser Dam.

| Out-migration |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
| Brood Year |  | Naches | American | Upper Yakima |
| 1997 | 1999 | 16.00\% | 10.79\% | 73.22\% |

| 2016 | 2018 | 28.52\% | 7.47\% | 57.91\% |
| 2017 | 2019 Genetic samples not yet available |  |  |  |
| Mean |  | 28.17\% | 11.61\% | 59.88\% |
| SE |  | 1.32\% | 1.39\% | 2.32\% |

There was an interaction between the proportions among stocks and years ( $\mathrm{F}_{32,255}=3.67, \mathrm{p}<0.01$, Figure 10. A), indicating that the contribution in the out-migrating smolt populations from the different stocks was different among years but the contribution percentage of one stock depends on another stock's contribution.

Figure 10. Proportion of each stock in the out-migrating smolt populations from 1999 through 2019 (data from WDFW, see table 10).

Table 9. Estimated Wild Spring Chinook stock distributions (American, Naches and Upper Yakima River) within the genetic sampling periods (from Pre-March through Post-May).

### 3.6. Relationship between Wild Juvenile passage estimates and estimated Adult Returns

Since the number of smolts out-migrating from Prosser (Prosser-passage estimates) varied among years, we further evaluated whether this variation corresponded to adult returns. Or in other words, does the fluctuation of annual wild juvenile Prosser passage (out-migrating smolts from Prosser) synchronize with the fluctuation of the adult returns at Prosser? To answer the question, we built a univariate relationship between the total Juvenile Prosser estimates of wild Spring Chinook and the predicted adult return to Prosser. Table 10 presents the brood year Prosser escapement (the escapement measures are taken as a surrogate of spawner number) of the parental generation in addition to total juvenile Prosser passage and Prosser return. The relationship between the escapement and estimated juvenile passage was not significant, however the correlation of total wild juvenile passage to adult return was significantly high (Figure 11). The year-to-year trends (Figure 12) between the total wild juvenile-passage adult return and estimated return seemed to be consistent and it was only $70 \%$ correlation.

Table 10. Total estimated wild escapement, juvenile passage and return to Prosser. Estimated value for the Prosser escapement and Prosser return were adopted from Table 10, and Table 3 of Bosch, 2020 , respectively. The shaded yellow color indicates no or incomplete estimates.

| Brood <br> Year | Out- <br> migration <br> Year | Prosser <br> Escapement | Total Juvenile <br> Prosser <br> Passage | Prosser <br> return |

### 3.7. Relationship between estimated Juvenile Prosser passage and river flow

### 3.7.1. Annual

The annual juvenile Prosser-passage estimate of wild and hatchery Spring Chinook tends to increase with the river flow, however this was significant only in the Upper Yakima hatchery smolts (See Figure 13).

Figure 13. The relationship between the annual estimate of the juvenile Prosser-Passage (total number of out-migrating smolts of Total Wild, Upper Yakima Wild and Upper Yakima hatchery) and the four month average river flow approaching Prosser Dam (March through June). The flow is the sum of the flow measured at the gaging stations CHCW and YRPW.

### 3.7.2. Daily

We further evaluated whether daily estimated number of wild out-migrating smolts is affected by daily river flow (the river flow approaching the dam, which is the sum of the flow measured at the gaging stations CHCW and YRPW). Figure 14 shows day-to-day trends of the estimated daily counts and the daily river flow. It showed that in general, daily estimated out-migrating smolts was high if the river flow was high, but this relationship was strong only in the months of March, April and May, which indicates that rate of out-migration from Prosser was a function of river flow during those months and, when smolt migration appears to be stalled, releases of pulses in flow from reservoirs can improve the rate of smolt out-migration.

Figure 14. Daily estimated counts of wild/natural Spring Chinook smoltsand river flow for the period in which Chandler Canal's monitoring facility was operated during 2019. Gaps in the estimated population (red line) represent the missing count data. The river flow (blue line) is the flow approaching the dam (sum of the flow measured at the gaging stations CHCW and YRPW). The arrows (green color) along the lines corresponding to river flow and estimated counts show synchronizing events between increasing river flow and increasing fish counts.

We further examined how much synchrony there was between daily river flow and outmigration population for each month of the 2019 sampling period. We analyzed scatter plots and linear relationships between the daily estimated counts of wild Spring Chinook and daily river flow and found that if river flow increased, the out-migrating smolt population increased in the months, March, April and May. The relationship between daily out-migration and river flow seemed to be
negative for Pre-March and Post-May, but it was not significant. However, the positive relationship was very strong for the months of March, April and May.

Figure 15. The relationship between daily estimated wild/natural Spring Chinook smolt passage and river flow for the period in which the Chandler Canal monitoring facility was operated during 2019.

## Executive Summary

This report summarizes the results of an evaluation to estimate survival rate and travel time of juvenile Spring Chinook Salmon (Oncorbynchus tshanytscha) released at the Roza Dam bypass during 2019. This evaluation is part of an ongoing study that was initiated in 1999. Differences between natural and hatchery rearing environments have a significant influence over the demographic attributes of natural- (born in the natural) and hatchery-origin Chinook salmon beginning in early developmental stages of fish. Moreover, hatchery-origin smolts released into the natural environment experience in-stream conditions that are dramatically different from a controlled hatchery rearing environment. Therefore, attempts to infer the survival rate for natural-origin smolts based on survival of hatchery-reared smolts (or vice versa) can be biased by relative differences in fish size, behaviors such as outmigration timing, fitness, and environmental conditions encountered during outmigration. Our investigation of interannual variation in survival rate and travel time for both natural- and hatchery-origin emigrating smolts will inform managers in the implementation of effective strategies for conserving abundances and viability of the natural spring-run Chinook Salmon population in the Upper Yakima River Basin.

In 2019, we tagged 2,238 hatchery-origin smolts and 238 natural-origin smolts with passive integrated transponder (PIT) tags at Roza Dam. Tagged fish were released from April 02 through May 10 at the Roza Dam bypass system. The size of tagged and released hatchery-origin smolts ranged from 88 mm to 187 mm (average 121 mm ). Hatchery fish were significantly larger than PITtagged natural-origin fish, which ranged in size from 77 mm to 147 mm (average 118 mm ).

Our results indicated variable travel times for hatchery- and natural-origin smolts in the population, based on travel between the Roza Diversion Dam's bypass (about 206 kilometers upstream from the mouth of the Yakima River) and the downstream detection site at McNary Dam, a distance of 64 rkm. Most fish in each group were released during the month of April, and fish generally exhibited immediate outmigration behavior after released. In 2019 the travel time from Roza Dam to McNary Dam for hatchery-origin smolts ranged from 4 to 40 days (mean $\pm$ SE $18.13 \pm 0.9$ days). By comparison, the travel time for natural-origin smolts ranged from 9 to 37 days ( $19 \pm 2.49$ days). Mean travel times in 2019 appeared to be shorter for both groups compared to the 2018 outmigration year ( $24.81 \pm 0.89$ days, and $36.81 \pm 3.08$ days for hatchery- and natural-origin fish respectively). Travel time was positively related with rate of river flow during emigration (outmigration), and results of analysis of variance (ANOVA) showed an interaction effect between fish size and groups (hatchery
and natural) on travel time. Specifically, hatchery fish which were larger on average exhibited shorter travel times (days to reach McNary Dam) compared to travel times of smaller, natural-origin fish. These results are consistent with Melnychuk et al. (2010) who found that in small rivers, downstream travel speed increased with increasing body length. In addition, downstream emigration timing and travel days are believed to be affected by many environmental variables, including photoperiod, river discharge, precipitation, lunar phase, air and water temperature, and fish size (Duston and Saunders 1995; McCormick et al. 1995; McCormick 2012; Sykes and Shrimpton 2009; Zydlewski et al. 2014).

In this study, the survival rates from release location to downstream detection at McNary Dam were estimated using the Cormack-Jolly-Seber (CJS) mark-recapture model, which has been commonly used within the Federal Columbia River Power System (FCRPS) to estimate survival rates for juvenile anadromous fish species (salmon and steelhead, see Tuomikoski et al. 2013). The model uses multiple detections of individual marked fish at several dams with PIT-tag detection capabilities. Rather than the CJS model, the data collected in prior years (1999 to 2018) was based on a logistic regression model described in the 2018 annual report. We further evaluated the effects of river flow on survival rate by introducing flow as a covariate in the CJS model. Results indicated that survival rate between the Roza Dam release site and the McNary Dam detection site was $28 \%$ and $31 \%$ for natural- and hatchery-origin fish, respectively; a similar result was observed in 2017 and 2018. Results also revealed that survival rate increased with increasing river flow during the downstream migration time but the effect was not significantly different between hatchery- and natural-origin smolts. However, when using mean survival rate of all previous years (21 years, 1999-2019), the survival rate was significantly higher for the natural-origin fish ( $\mathrm{F}_{1,34}=0.778, \mathrm{p}=0.028$ ). Since all fish were released in April (late release) last year, no comparisons were made between early and late periods (i.e. monthly) for the last year, 2019. Further, we were unable to estimate juvenile survival rates by weekly basis for some of the groups because of high standard errors (SE) in some weeks or because the model failed to converge (convergence issue), indicating insufficient sample sizes for estimating it on weekly basis especially for natural-origin juveniles.

### 1.0 Introduction

In recent years, naturally spawning Pacific salmon populations have declined relative to historical abundances, resulting in many ESA listings, and heightened conservation concerns (Prince et al. 2019; Rand et al. 2012; Ford 2011; Gustafson et al. 2007). The recovery of depressed stocks is contingent on obtaining accurate and precise estimates of survival through the hydro system. Juvenile salmon emigrating from the Yakima Basin must navigate downstream through several dams in the Yakima and Columbia rivers during migration to the ocean. For over a decade, hatchery production in Yakima basin has been used to supplement natural salmon populations in order to benefit fisheries opportunities, and to boost declining natural populations. These hatchery programs are likely to continue and possibly increase significantly within the Columbia River Basin (WDFW 2019).

Since 1999, the Yakama Nation has been conducting a study to examine juvenile salmon survival, with a focus on understanding whether or not survival, and the factors affecting survival, are similar between hatchery-origin and natural-origin components of the population. The study involves annual releases of hatchery-origin and natural-origin Chinook salmon (smolt) that have been inserted with passive integrated transponder (PIT) tags. There is some evidence to suggest that captiverearing of salmon under certain hatchery protocols (e.g. segregated programs) confers a genetic fitness deficit (domestication) to hatchery fish released into the natural environment compared to naturally reared salmon (Lynch and O' Hely 2001; Ford 2002; Frankham et al. 2002). This is especially poignant for hatchery-origin smolts that are exposed to highly inconsistent environments between captive rearing conditions and the natural in-river conditions they experience after release. Differences between natural and hatchery rearing environments have a significant influence over the demographic attributes of natural- and hatchery-origin Chinook salmon beginning in early developmental stages of fish. Inferring survival rates for natural-origin smolts based on survival rates for hatchery-rearing smolt can be misleading due to differences in fish size, behavior, fitness, and environmental conditions encountered during outmigration (e.g., predisposition or acclimation). Hatchery-origin smolts are often larger owing to feed regimens and accelerated growth rates implemented during hatchery rearing.

Further, the survival rate, which is also dependent on river flow and fish size during the outmigration period (Zabel and Achord, 2004). With regard to survival, juvenile outmigration (and
travel time) is a particularly critical phase in the overall life history of salmon (NPPC, 1992). Mortality rate is likely to increase as a function of migration distance (often hundreds of miles), where risk is compounded by exposure to several factors, including predation, extreme temperatures and diseases (Miller et al., 2014), and entrainment at diversions or dams. Furthermore, outmigration is concurrent with the smoltification process, where a fish undergoes physiological, behavioral and biochemical changes in preparation for saltwater habitat (Hoar 1976). Therefore, it is vital that the coordination between smoltification, outmigration, and arrival time to the estuary be preserved (Folmar and Dickhoff 1980); that is, outmigration and travel time must remain commensurate (on schedule) with physiological readiness for saltwater.

The downstream emigration timing and travel days are believed to be affected by many environmental variables, such as fish size, photoperiod, discharge, precipitation, lunar phase, water temperature and type of origin (natural vs. hatchery) (Duston and Saunders 1995; McCormick et al. 1995; McCormick 2012; Sykes and Shrimpton 2009; Zydlewski et al. 2014). In order to determine whether or not downstream survival rate and downstream migration dynamics (e.g., travel time) of juvenile Chinook (Smolt) differ between natural and hatchery populations, our study focused on the following objectives:

1) evaluate the survival rate from the released location (Roza dam) to McNary Dam (McN) between hatchery- and natural-origin smolts based on PIT-tag detections,
2) determine if survival rate is significantly different between early and late release groups,
3) determine the effect of river flow on survival rate for both groups (hatchery- and natural-origin), and
4) determine whether or not downstream migration dynamics (e.g., travel time) differ between natural and hatchery smolts in Yakima river.

### 2.0 Methodology

We queried the PTAGIS database (https://www.ptagis.org/) in February 2020 to retrieve available PIT-tag detection information for all spring Chinook Salmon smolts (hatchery- and natural-origin) released at Roza Dam in the Yakima Basin between 2015 and 2019 (Roza bypass; Fig. 1). A total of

2238 hatchery-origin smolts and 238 natural-origin smolts with passive integrated transponder (PIT) tags were released from April 02 through May 10, 2019 at the Roza bypass system (Fig. 2).

Hatchery-origin juveniles were acclimated at three sites upstream of Roza Dam (Jack Creek, Easton, and Clark Flat; Fig. 1). Travel time and survival estimates were compared between PIT-tagged hatchery-origin smolts and PIT-tagged natural-origin smolts beginning when hatchery-origin juveniles were tagged/released at the Roza Dam bypass. Natural-origin smolts were identified as "early" for those sampled and PIT-tagged before the first hatchery-origin smolts were sampled, and "late" for those sampled and PIT-tagged once hatchery-origin fish were released in the Roza bypass sample. In each release year, survival-estimate comparisons were made between late and early natural smolts, and travel time was measured as the difference between the release date at the Roza bypass and recovery/detection date at the downstream dam/detection facilities at McNary Dam.

Although the survival rate from Roza Dam to McNary Dam in each year from $1999^{+}$to 2018 was estimated using weighted logistic regression (see Neeley, 2018), the survival rates for both groups (natural- and hatchery-origin smolts) for the last 5 years (2015-2019) were estimated using the Cormack-Jolly-Seber (CJS) mark-recapture model (see, White and Burnham 1999; Lebreton et al. 1992; Williams et al. 2002; Conner et al. 2015), in accordance with Federal Columbia River Power System (FCRPS) methodology (Tuomikoski 2013). The CJS model uses multiple detections of individual marked fish at several dams equipped with PIT-tag detection capabilities. The assumption of the CJS model is that there is no immigration or emigration during capture and recapture intervals, which is valid in the hydrosystem (which involves passage at several hydroelectric dams) because fish behavior is relatively consistent (all fish are moving in one direction and over a relatively short period; see Conner et al. 2015). The CJS model was originally conceived to calculate time-interval survival of tagged animals by recapturing individuals and estimating survival and recapture probabilities using maximum likelihood. A spatial form of the CJS model can be used for species that migrate uni-directionally, and are recaptured/detected within a discrete migratory corridor (Burnham 1987; Henderson et al. 2018). We used individual fish encounter histories to estimate the likelihood that a fish would survive and be detected at each tag receiver facility (i.e. dams; Lebreton et al. 1992).

The CJS model was run for different groups by year based on an encounter history constructed

[^11]from the number of fish released at Roza dam and subsequent detection events at McNary and Bonneville Dams. Similar to previous studies (Neeley 2018), all smolt releases were grouped into seven-day periods for analyses. For example, smolts released during ordinal days 1-7 and 8-14 were treated as two distinct release groups. These groups are referred to as Julian/ordinal periods. The estimated survival rates were compared among release groups where the sample sizes were sufficient to provide statistical confidence. Analysis of variance (ANOVA) was performed to evaluate differential survival between hatchery- and natural-origin smolts, using group (hatchery-origin vs. natural-origin) and release period (early and late) as factors and years as replicates. Note that there were no PIT-tagged smolts released for our study in 2014 due to the occurrence of a radio-tagged study being conducted at Roza in that year. Although a radio-tag study was also conducted in 2016, the temporal overlap with PIT-tag releases in our study was minimal, enabling estimation of Roza-to-McNary survivals based on a smaller number of releases.

Several environmental factors are known to influence downstream smolt survival, and river flow is among the most impactful (Raymond 1968; Connor et al. 2003; Tiffan et al. 2009). We therefore further evaluated survival rate with the effects of river flow by introducing flow rate as a covariate in the CJS model. Bureau of Reclamation (BOR) flow data were accessed at:
https://www.usbr.gov/pn/hydromet/yakima/yakwebarcread.html. The average travel time from Roza Dam to McNary Dam was about 20 days (both hatchery-origin and natural-origin smolts) so that the time series river flows were averaged by 20 days using a moving averaging technique. For example, a fish released on April $1^{\text {st }}$ would reach McNary Dam by about April 20 th , and the 20-day average flow rate for that time period would be assigned for that fish to determine the effect of river flow survival.

Several CJS candidate models were built and compared using every possible combination of variables in the models with river flow. For example, candidate models were defined using a combination of 1) two temporal variation in survival probability: time variation, which assumed that survival probability $(\psi)$ varies by year; and no time variation which assumed that $\psi$ remains constant for all years; and 2) two temporal variation in detection probability: time variation, which assumed that detection probability varies by year; and no time variation which assumed that detection remains constant for all years; 3) variation of survival and detection probabilities between natural- and Hatchery-origin, and 4) influence of river flow on the survival and detection probabilities. Altogether, 49 models were built using these combinations (see table 3).

To determine the rank of the different models (49 models), we used the difference in QAICc score relative to the top model. For models with the difference of QAICc (QAICc) $<2$, we selected the model with the lowest QAICs and fewest parameters as the best model (Burnham and Anderson 2002). We tested the Goodness of Fit (GOF) of competing models using the Bootstrapping Goodness of Fit Approach ("Bootstrap GOF") in program MARK (Cooch and White 2012) to estimate the variance inflation factor for the model constructed to have the most parameters while remaining biologically meaningful (hereafter referred to as the "global model"). All subsequent models were then corrected for over-dispersion using c-hat ( $\hat{c}$ ). Using the best selected model, we estimated the effect of river flow on downstream survival rate (Roza Dam to McNary Dam) for both groups (hatchery- and natural-origin smolts). The CJS models and program MARK (White and Burnham 1999) were run within the RMark package (Laake and Rexstad 2019) in R statistical software, version 3.3.6 (R Core Team 2019).

Figure 1. Showing Yakima river and Roza Dam where the fish (hatchery- and natural-origin) were captured/tagged/released. Survival rate and travel time were estimated between Roza Dam and McNary Dam. Hatchery-origin smolt exited either from Easton, Jack Creek or Clark Flat acclimation sites during March 9 through May 16, 2019. The map was adopted from Fast et al., (2015).

Figure 2. Number of spring Chinook tagged/released at Roza Dam (Hatchery-origin smolt, red; and natural-origin smolt, blue) for each year from 2015-2019. The value on the top of the bar diagram represents the total number of released smolt on that specific day of that year. Total released number of released PIT taggs fish (natural and hathery-origin) of each are also given in the figure.

Date of release in 2019

### 3.0 Results and Discussion

### 3.1 Fish sizes

During the last five years (2015-2019), fish with passive integrated transponder (PIT) tags were released for this study from early February to May at the Roza bypass system. Releases started in February and ended on May in 2015, whereas from 2016-2019, fish were released from the second week of March through the $1^{\text {st }}$ week of May (see figure 2).

Last year 2019, 2238 hatchery-origin smolt and 238 natural-origin smolt with PIT tags were released and the size of the released hatchery-origin smolt that were PIT-tagged at the dam ranged from 88 mm to 187 mm (mean 121 mm ), whereas the range of the size of the natural-origin smolt was 77 mm to 147 mm (mean 118 mm size; figure 3). The size of released hatchery-origin smolts was significantly larger than that of natural-origin smolts ( $\mathrm{F}_{1,8}=16.87, \mathrm{p}<0.01$ ).

Figure 3. Frequency distribution of the fish size of the populations (hatchery and natural-origin smolt) released with PIT tags at Roza Dam. Size of the fish was measured at the time of tagging for each year 2015-2019 before release.

### 3.2 Yakima River flow below Prosser Dam

The river flow below Prosser dam (gauging station YRPW, which represents the reach between Prosser Dam and the Chandler Power Plan outfall) during the month of April (fish tagged/released month) in the year 2019 was about 4,444 cubic feet per second (cfs), which was slightly lower than the flow of that month during 2016 and 2017 but it was higher than April 2015 (see figure 4, table 1). For all years, the river flow from June to August was generally less than 800 cfs.

Figure 4. Average daily River flow (cfs, blue line) and 20-day average flow (20 day moving average, yellow line) of Yakama River near Prosser dam from January to December for 2015-2019. The boxes with red color are the period in which the fish (natural- and hatchery-origin) were tagged/released during that year.

Table 1. Average monthly river flow (cfs) of Yakama River below Prosser dam for 2015-2019.

|  | Month |  |  |  |  |  |  |  |  |  |  |  |
| :---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |

| 2015 | 4793 | 4420 | 2523 | 1043 | 895 | 420 | 387 | 526 | 581 | 892 | 3549 | 5237 |
| 2016 | 2632 | 8603 | 7982 | 8600 | 3437 | 983 | 822 | 519 | 517 | 2086 | 2582 | 1920 |
| 2017 | 1696 | 3460 | 9492 | 8778 | 6959 | 2697 | 640 | 666 | 657 | 1463 | 3585 | 2434 |
| 2018 | 3038 | 4138 | 2632 | 5183 | 6183 | 994 | 574 | 604 | 542 | 1054 | 1489 | 1775 |
| 2019 | 1389 | 1536 | 3066 | 4444 | 1860 | 563 | 560 | 749 | 568 | 1041 | 1458 | 2122 |

### 3.3. Travel time from the release site (Roza Dam) to McNary Dam

The study showed that the travel time (days) of smolts from the release site (Roza Dam) to McNary (McN) dam during 2019 varied between hatchery- and natural-origin smolt (figure 5). Most of the populations were released during the month of April and most of the fish generally exhibited immediate outmigration behavior after release. One of the hatchery-origin smolts was detected at McN only 4 days from the date of release at Roza Dam. In 2019 the travel time from Roza Dam to McNary Dam for hatchery-origin smolts ranged from 4 to 40 days (mean $\pm$ SE $18.13 \pm 0.9$ days). By comparison, the travel time for natural-origin smolts ranged from 9 to 37 days ( $19 \pm 2.49$ days). Mean travel times in 2019 appeared to be shorter for both groups compared to the 2018 outmigration year ( $24.81 \pm 0.89$ days, and $36.81 \pm 3.08$ days for hatchery and natural-origin fish respectively). Variation of the travel time among years might have occurred due to the variation of the river flow among years. The study further showed the travel time from Roza to McNary dams decreased as river flow at the time of fish release increased (figure 6 B). Similarly, travel time varied between groups (hatchery- and natural-origin) due to fish size because the hatchery-origin smolts were larger than natural-origin smolts (figure 6A). Travel time was positively related with rate of river flow during emigration, and results of analysis of variance (ANOVA) showed an interaction effect between fish size and groups (hatchery and natural). Specifically, hatchery fish, which were larger on average exhibited shorter travel times (days to reach McNary Dam) compared to longer travel times for smaller, natural-origin fish. These results are consistent with Melnychuk et al. (2010) who found that in small rivers, downstream travel speed increased with increasing body length. In addition, downstream emigration timing and travel days are believed to be affected by many environmental variables, including photoperiod, river discharge, precipitation, lunar phase, air and water temperature, and fish size (Duston and Saunders 1995; McCormick et al. 1995; McCormick et al. 2000; McCormick 2013; Sykes and Shrimpton 2009; Zydlewski et al. 2013; Zydlewski et al. 2014).

Figure 5. Number of detections of PIT-tagged smolts released at Roza dam during 2015 to 2019 at McNary Dam by day (month/day; e.g., 3/31 means March 31, and so on). The table in each year shows the summary of the travel time from Roza to McNary dams.

Figure 6. The relationship between travel days from Roza dam to McNary ( McN ) dam and fish size at the time of tagging of both groups (hatchery- and natural-origin) during 2015-2019 ([A.]); and the relationship between the average travel time (days) from release site (Roza dam bypass) to McNary dam and the average river flow during the months in which these fish were released for 2015-2019 ([B.]).

### 3.4. Survival rate of hatchery- and natural-origin smolt

Based on CJS model, the average survival probability from Roza Dam to McNary Dam for the populations (a combination of hatchery- and natural-origin smolt) released at Roza dam during 2019 was $31.6 \pm 6.60 \%$ (mean $\pm$ SE), however the hatchery-origin survival rate was $31.8 \pm 7.00 \%$, which was slightly higher than the natural-origin smolt ( $28.80 \pm 17.40 \%$ (see Table 2 ). A similar result was observed in 2017 and 2018. The results further showed the standard error of the mean for the natural-origin in 2019 was relatively larger than the error for hatchery-origin smolt estimates. The SE can be reduced if released population size increases.

Table 2. Released and detected population at McNary (McN) and Bonneville (BON) Dams and Roza-to-McNary survival rate for all (combination of hatchery- and natural-origin), hatchery- and natural-origin juvenile (smolt) for the last five years (2015-2019). Note: there were 5 groups and each group contains the number which represent the number of fish and detected events at the downstream dams. " $1-0-0$ " is represented as the number of fish released at Roza dam (1) but not detected at both $\mathrm{McN}(0)$ and BON (0) dams; similarly, "1-0-1" represents the number of fish released at Roza dam (1) and not detected at $\mathrm{McN}(0)$ but detected at BON (1) dam. "1-1-0" represents the number of fish released at Roza dam (1) and detected at McN (1) but not detected at BON (0) dam. "1-1-1" represents the number of fish released at Roza dam (1) and detected at both McN (1) and BON (1) dams.

| Year | Groups | Type |  |  |
| :---: | :---: | :---: | :---: | :---: |
|  |  | $\begin{gathered} \text { All } \\ (\mathrm{H}+\mathrm{W}) \end{gathered}$ | Hatchery-origin <br> (H) | Natural-origin (W) |

|  | 1-1-1 | 5 | 5 | 0 |
|  | Survival rate | $0.316 \pm 0.128$ | $0299 \pm 0.12$ | *** |
| 2016 | 1-0-0 | 1070 | 946 | 124 |
|  | 1-0-1 | 31 | 31 | 0 |
|  | 1-1-0 | 125 | 113 | 12 |
|  | 1-1-1 | 14 | 14 | 0 |
|  | Survival rate | $0.360 \pm 0.077$ | $0.370 \pm 0.079$ | *** |
| 2015 | 1-0-0 | 1807 | 1334 | 473 |
|  | 1-0-1 | 37 | 28 | 9 |
|  | 1-1-0 | 101 | 62 | 39 |
|  | 1-1-1 | 11 | 8 | 3 |
|  | Survival rate | $0.249 \pm 0.064$ | $0.22 \pm 0.065$ | $0.321 \pm 0.154$ |

*** indicates the models failed to converge so that the survival rate was not able to be estimated.

Figure 7. The box plot showing the 20 -year average survival probabilities of natural-origin (Natural) and hatchery-origin (Hatchery) smolt (see table 4 for the data). A. is the comparison of Late hatchery- and natural-origin smolt; and B. is the comparison between Early and Late natural-origin Smolt.

### 3.5. Effect of river flow on the survival rate

We further evaluated whether the river flow affects the outmigration survival rate for hatchery- and natural-origin smolts. Among the 49 models (see table 3), the top two models had the lowest QAICc. The difference between first and second models was less than 2, indicating that both models seemed to be the best models to describe the relationship. However, the model that included an effect of river flow on the survival rate for the groups but varied by years had the lowest QAICs and therefore this model was selected to illustrate the effects of river flow on survival. Based on the best model, the survival rate between Roza and McNary Dams was positively related with the river flows for all years (2015-2019) (see table 3 and figure 8).

Table 3. Candidate models and associated statistical parameters. The models are ranked based on Quasi-likelihood Akaike's Information Criterion adjusted for over-dispersion (QAIC ${ }_{c}$ ). The model with the lowest $\mathrm{QAIC}_{\mathrm{c}}$ value was considered 'best'. "Wt" represents the weight of the model. S and $p$ represent survival and capture probability, respectively. "npar" represents the number of parameters used in the model. The models were built using last 5 years data.

| SN | Models | npar | QAICc | Delta( $\Delta$ ) | Wt |
| :---: | :---: | :---: | :---: | :---: | :---: |

### 3.6. Comparison of Natural- and Hatchery-Origin Smolt Survival to McNary

 Dam of Roza releases during the "Late" release periodYearly survival estimates based on all contemporaneous late-period smolt are given in Table 4 and Figure 9A. Because natural-origin smolt have spent more time in the natural habitat than hatchery-origin smolt by the time fish pass Roza Dam, it has always been hypothesized that, for smolt contemporaneously released at Roza, the survival to McNary of natural-origin smolt would be greater than that of hatchery-spawned smolt even though the hatcheryorigin fish tend to be larger. However in 2019, the survival rate of hatchery-origin smolts was greater than that of natural-origin smolts (fig. 9A) and a similar result was observed in 2017 and 2018. However, when using mean survival rate of all previous years (21 years, 1999-2019), the survival rate was significantly greater for the natural-origin fish $\left(\mathrm{F}_{1,34}=0.778\right.$, $\mathrm{p}=0.028)($ fig. 7 A$)$.

Table 4. Upper-Yakima Spring-Chinook Roza to-McNary Smolt-to-Smolt Survival for Natural- and Hatchery-Origin (Early and Late) juvenile (smolt). N, Surv. and SE in the table represent the number of released tagged fish, Roza-to-Mcnary Survival probability and standard Error of the survival probability, respectively.

Note: the estimates for the year from 1999 to 2018 were adopted from the 2018 Annual report (Neeley 2019).

### 3.7. Comparison of Early and Late Natural-Origin Smolt Survival to McNary

There were no early natural-origin fish releases at Roza prior to passage of hatchery-origin smolt in 1999, 2010, 2017 and 2019; and, as stated earlier, there were no PIT-tagged releases at Roza Dam in 2014. Table 4 and Figure 9B. present the natural-origin early and late smolt survivals from Roza to McNary for all years. Of the 17 years with early releases, late releases had greater Roza-to-McNary survival than that of the early releases but the difference was not quite statistically significant $\left(\mathrm{F}_{1,34}=0.679, \mathrm{p}=0.26\right.$, Fig 7 B$)$. In general, earlier passing smolts are believed to have a greater survival rate. However, the results showed that later releases did not have significantly lower survival rates. A lower survival rate for earlier releases could be due to a lower proportion of out-migrates enter into juvenile bypass systems where PIT tags can be detected. Generally, McNary Dam's bypass is watered up after Julian date 90 , so fish passing earlier would be spilled rather than bypassed, which results in reducing of the detection rate, consequently survival rate become low. It may also be that some of the early natural-origin releases pass McNary Dam before they could be detected in McNary's bypass, in which case the early-release natural survival estimates presented herein may be underestimated.

### 3.8. Weekly survival rate of natural- and hatchery-origin Smolt

The survival rate (Roza-McNary Dam) varied by week for both groups (natural- and hatchery-origin), however the number of natural-origin releases were not sufficient to estimate the weekly survival rate with statistical confidence. In general, the hatchery-origin smolts that were released early [Julian date 91, which was the week of April 1st to $7^{\text {th }}, 2019$ ) had higher survival rate $(78.21 \% \pm 7.4 \%)$ than the smolts released during the week Julian date 126] between May 7 and May $12^{\text {th }}, 2019$ ( $27.2 \pm 14.88 \%$, see table 5 and figure 10).

Figure 9. Bar-diagram of Upper-Yakima Spring-Chinook Roza to-McNary Smolt-to-Smolt Survival for Late Natural- and Hatchery-Origin juvenile. A. is the comparison of Late hatchery- and Late Natural-origin smolt; and B. is the comparison between Early and Late Natural-origin Smolt.

Table 5. Roza-Dam to McNary-Detection Smolt-to-Smolt Survival probability with respect to Julian week. "Sur" and " N " represent survival probability and the number of smolts tagged and released, respectively.

| Origin | Param eter | Julian Date |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  | Early | Late | Over <br> All |

### 4.0 Acknowledgment

We thank all of the crews whose collective fish-tagging efforts over the years made this study possible. We are also grateful to Andrew Matala and David Lind who reviewed and provided valuable comments in the draft report. We would also like to thank Daylen Isaac who provided the hydrological data.

## Executive Summary

Coho Salmon (Oncorbynchus kisutch) in the Yakima basin were extirpated in the early 1980s but reintroduction efforts initiated in the mid-1980s have resulted in hatchery-produced coho naturally reproducing in both the Yakima and Naches rivers. In 1984 there was no escapement ( $\mathrm{n}=0$ ) of adult Coho Salmon returning to the Yakima Basin, but the return of hatchery-produced origin fish peaked in 2014 ( $>25,000$ adults). Several release strategies for outplanting fish have been implemented in the reintroduction program to evaluate and compare relative survival and escapement. Outplants have been released at both the parr and smolt life stages, including different size classes, released at multiple locations, including different release dates, and outplanted from different broodstock sources. A diverse strategic approach was utilized to maximize the likelihood of achieving stable and abundant returns of natural-origin Coho Salmon to the Yakima River and to enhance the stability and resiliency of the population against potential environmental changes.

An ongoing, long-term monitoring program is being conducted with the aim of improving project objectives and strategies by applying what is learned from the project experiments, monitoring and evaluation, and literature reviews in an adaptive management framework. This evaluation is an update of ongoing annual monitoring that was initiated with the inception of reintroduction efforts in 1996. The report summarizes the results for estimated survival rate and travel time of juvenile (Smolt and Parr) Coho Salmon released from multiple locations in the Yakima basin with a focus on the following objectives:

- Determining survival rate and travel time of smolts released in 2019 and parr released in 2018 (migration year 2019)
- Comparing survival rates between outplants from different broodstock sources (Yakimabroodstock vs. out-of-basin either from Eagle Creek National Fish Hatchery or Washhougal Hatchery)
- Identifying watershed-specific survival rates between the upper Yakima River and Naches River locations for out-migrating juveniles, and identifying whether survival differs as a function of release month (February, March, April)
- Evaluating the effects of river flow (e.g., monthly variation) on outmigration survival rate

In 2019, fish from two brood sources (Yakima and Eagle Creek) were released during the time period March 21 to April 15. Smolts from the in-basin Yakima stock were released in the lower Yakima River at Ahtanum Creek and Prosser Dam and in the upper Yakima River (upstream of Roza Dam) at the Jack Creek Spring Chinook acclimation site and in Wenas Creek. The out-of-basin Eagle Creek smolts were released in the upper Yakima River at Easton and Holmes sites and in the Naches River at the Stiles site; all smolts were released on April 15 ${ }^{\text {th }}$. In total the releases included 20,305 PIT-tagged smolts, ranging in size from 67 mm to 101 mm (average 105.5 mm ). There was no significant difference in smolt size between the release groups at the different release locations during 2019.

Unlike smolts which begin emigration immediately after release, the released parr typically outmigrate as yearling smolts in the spring following their release. Parr releases were made into the Yakima and Naches rivers at 10 locations during 2018 or 2019 migration year (Ahtanum Creek, Cowiche Creek, Little Naches River, Naches River, Rattlesnake Creek, Big Creek, Reecer Creek, Swauk Creek, Wilson Creek, and upper Yakima River).

Our results indicated variable travel times to McNary Dam for smolts released at the different locations. Fish released at Prosser Dam exhibited the shortest travel time to McNary Dam (mean $21.32 \pm 8.54$ days), whereas the Jack Creek release group had the longest travel time (mean $47.14 \pm$ 4.59 days). Travel times for the groups released at the Easton, Holmes and Stiles ponds, Wenas Lake, and Ahtanum Creek ranged from 33 to 39 days. On average, for the 2015-2019 migration years, parr releases were detected at McNary Dam after 320 days following release, ranging from a minimum of 200 days to a maximum of 700 days. Interestingly, 11 fish were detected at the McNary Dam juvenile facility moving downstream after spending almost 2 years in the freshwater in the migration year 2015 and 2016. Moyle (2002) also reported that most coho salmon smolts leaving California streams reportedly are 12 to 15 months old but some juveniles reportedly stay in the stream 2 years before emigration.

The overall smolt detection rate at McNary Dam was $9.96 \% \pm 1.31 \%$ in 2019, which was similar to the detection rate of $9.25 \% \pm 0.9 \%$ in 2018. However, McNary detection rates varied among the Yakima River release groups. The detection rate was highest for the Prosser release group $(20.28 \% \pm 2.7 \%)$, followed by Easton Creek ( $5.94 \% \pm 2.3 \%$ ), Jack Creek and Stiles ( $4.76 \% \pm 4.6 \%$ ), Holmes $(0.2 \% \pm 0.08 \%)$, Ahtanum $\left(0.01 \% \pm \mathrm{NA}^{2} \%\right)$, and Wenas Lake at upper boat lunch $(0.03 \% \pm$
$0.02 \%$ ). In addition, McNary Dam detection rates were generally lower for fish released from upper Yakama River locations in May and June. This is likely due to higher mortality associated with lower river flows and/or increasing water temperature in the lower Yakima River during those months. Flows typically decrease beginning in the first week of May as irrigation diversions become operational in the basin. Similar to smolt releases, detection rates at McNary Dam of smolt for parr releases were variable among years. Only a few McNary Dam detections were observed for parr releases compared to smolt releases.

For data collected in prior years (2007 to 2018), a logistic regression model (see Neeley 2012) was used to estimate survival. Beginning in 2019 and in this report, survival rates from release locations to downstream detection at McNary Dam were estimated using the Cormack-Jolly-Seber (CJS) mark-recapture model, which has been commonly used within the Federal Columbia River Power System (FCRPS) to estimate survival rates for juvenile anadromous fish species (salmon and steelhead, see Tuomikoski et al. 2013). The model uses multiple detections of individually marked fish at several dams with PIT-tag detection capabilities (i.e. antenna arrays).

The average survival probability of Coho Salmon smolts from the release sites to McNary Dam in 2019 was $14.27 \pm 2.64 \%$, which was lower than both the 2017 estimate ( $29.06 \pm 3.4 \%$ ) and 2018 estimate ( $24.51 \pm 3.2 \%$ ), but higher than the 2015 estimate ( $10.12 \pm 1.14 \%$ ). Fish released at the Prosser site had higher ( $25.19 \% \pm 2.85 \%$ ) survival compared to releases at all other locations. The survival rate was higher for the Yakima-stock releases ( $17.51 \pm 0.8 \%$ ), followed by Eagle Creekstock release ( $15.04 \pm 2.4 \%$ ) and Washougal-stock release ( $8.49 \pm 1.6 \%$ ). For the parr-release group, the survival rate of the group was smaller than the survival rate of the smolt-release group, however the inter-annual variation of the survival rates among these years is similar to that for smolt-releases.

Since smolts were released over a three-month period (February, March and April), release date might also have affected survival. Therefore, using PIT-tag data from 2015 - 2019 releases, the effects of river flow and release month were introduced as covariates in the CJS model. The results showed that effect of river flows on outmigration survival rate depend on the release months (February, March and April). However, among the release months fish released in March had a higher survival rate compared to February and April.

Parr were released in the different locations listed above from May to October in the years preceding migration years 2015-2019. Release site-to-McNary survival of the parr-releases was higher for the population released in August $(14 \% \pm 0.020)$ and followed by the group of releases that was released in July $(3.1 \% \pm 0.40)$ and June ( $1 \% \pm 0.4$ ).

## 1. Introduction

Prior to their extirpation in the early 1980's, Coho Salmon (Oncorhynchus kisutch) in the Yakima Basin were once widely distributed among tributaries of the Yakima and Naches rivers (Fulton 1970; Chapman 1986), with annual adult returns numbering from 44,000 to 150,000 (Kreeger and McNeil 1993). Releases of hatchery reared Coho Salmon in the Yakima Basin began in 1983 with the first release of 324,000 smolts from the Little White Salmon Hatchery (YN 1997). In 1988, the YN and Washington department of Fish and Wildlife developed and implemented a reintroduction program that has successfully shown evidence of natural production in both the Yakima and Naches rivers. The highest return of adults (2014) from hatchery releases was greater than 25,000 fish; whereas in 1984 there was no escapement $(\mathrm{n}=0)$ of adult Coho Salmon returning to the Yakima Basin.

Several alternative release strategies have been utilized in the reintroduction program over time in response to observations in long-term monitoring. For example, smolts were initially only released in the mainstem of the Yakima River (Dunnigan et al. 2002). Subsequently, releases have been expanded to include a range of different locations to understand how variable habitat conditions (geographical area or watershed) affect the survival and productivity of returning adult salmon. Habitat capacity/quality have a significant impact on growth rate and survival, and within the Yakima River Basin human alterations to the environment continue to exacerbate naturally limiting conditions by reducing the quality and quantity of available spawning and rearing habitat. On the other hand, broad habitat restoration programs are concurrently being implemented to improve the habitat condition in many areas of the river. Other exploratory methods for evaluating relative success have included variable life stages (parr vs. smolts) at release, different release times, and use of multiple outplant sources. In past years, the primary sources of Coho outplants have come from Yakima basin returns, Eagle Creek National Fish Hatchery and Washhougal hatchery. In total, about 500,000 juvenile coho have been released each year, directly from acclimation sites or from temporary mobile acclimation facilities operated in upstream locations in tributary streams of the Naches and upper Yakima rivers.

Columbia River Coho Salmon typically spend one year in freshwater before out-migrating as yearling smolts in the spring (April-May). Adults commonly mature at sea for $\sim 18$ months before returning to natal streams as age-3 spawners. However, precocious, sexually mature males (jacks) may also return to spawn after 6 months at sea. Adult coho salmon generally migrate upstream at water
temperature ranging from $7.2^{\circ} \mathrm{C}$ to $15.6^{\circ} \mathrm{C}$ (Reiser and Bjornn 1979 cited in Laufle et al. 1986) and its spawning occurs from late October to November, sometimes as late as December or January. Spawning normally occurs in riffles or where ground water seepages occur, in minimum water depth of 0.18 m , at water temperatures ranging from $4.4^{\circ} \mathrm{C}$ to $9.4^{\circ} \mathrm{C}$, and velocities ranging from 0.3 to $0.91 \mathrm{~m} / \mathrm{sec}$ (Thompson 1972, BOR 2007). The optimum temperature for coho salmon egg incubation was $4^{\circ} \mathrm{C}$ to $11^{\circ} \mathrm{C}$ (Davidson and Hutchinson (1938 cited in Sandercock 1991). Juvenile coho salmon survive best in low-gradient habitats (generally less than four percent, (Jones and Moore, 1999) and tributaries with a stream gradient less than $3 \%$ with complex and deep pools or beaver ponds Bradford et al. (1997) and Reeves et al. (1989). Coho salmon generally spend one growing season in freshwater and two growing seasons (about 18 months) in the ocean before returning as 3 -year-old adults (Hassler 1987) to spawn in their natal streams (Beamish et al. 2004).

An ongoing, long-term monitoring program is being conducted with the aim of improving for project objectives and strategies by applying what is learned from the project experiments, monitoring and evaluation, and literature reviews in the YKFP adaptive management policy. This evaluation (report) is an update of ongoing annual monitoring that was initiated since 2001. This report summarizes the results for estimated survival rate and travel time of juvenile (smolt and parr) Coho Salmon released from multiple locations in the Yakima basin, with a focus on the following objectives:

* Determining survival rate and travel time of smolts released in 2019 and parr released in 2018 (migration year 2019)
* Comparing survival rates between outplants from different broodstock sources (Yakima broodstock vs. out-of-basin either from Eagle Creek National Fish Hatchery or Washougal Hatchery)
* Identifying watershed-specific survival rates among upper Yakima basin and Naches basin locations for out-migrating juveniles, and identifying whether survival differs as a function of release month (February, March, April)
* Evaluating the effects of river flow (e.g., monthly variation) on outmigration survival rate

These objectives have helped to answer a few research questions: such as 1 ). which released location has a better out-migrating survival rate? 2). What acclimated smolt release timing (early or late; or releases months Feb, March or April) provides the best juvenile survival rate? 3). Which broodstocks (out-of-basin vs. local) has the highest juvenile survival rate? And; 4). What are the effects of the river flow on juvenile outmigration survival rate for the early and late releases?

## 2. Methodology

### 2.1. Geographical distribution: historical and current

Coho salmon were native to the Yakima River basin and its spawning area was quite widespread in the Yakima River basin, including the Bumping River (Wydoski and Whitney 2003; Tuck 1995). Historically, it was assumed that Coho were present in low-gradient streams in the Yakima Basin prior to extensive habitat alteration and were widely distributed among tributaries of the Yakima and Naches rivers (Haring 2001; Berg and Fast 2001; Figure 1A). Acclimation and release sites designated in the reintroduction program overlap this historical geographical distribution (Figure 1B).

Figure 1. Historical Coho geographical distribution (A); the tributaries where smolt or parr releases were introduced 2008-2019 (B).

### 2.2. PIT-tag Data

We queried the PTAGIS database (https://www.ptagis.org/) in February 2020 to retrieve available PIT-tag detection information for all Coho Salmon smolts released at the different locations in the Yakima Basin from 2015 to 2019 (Figure 1). Numbers of PIT-tagged fish released each year among sites in the Yakima Basin ranged from 14,412 in 2017 to 20,305 in 2019 (Figure 1, Table 1).

Two outplant stocks (in-basin:Yakima and out-of-basin:Eagle Creek) were released between March 21 and April 15 in 2019. Smolts from the in-basin Yakima stock were released in the lower Yakima

River at Ahtanum Creek (March 21) and Prosser Dam (April 2), and in the upper Yakima River (upstream of Roza Dam) at the Jack Creek acclimation site (April 11) and Wenas Creek (April 15). The out-of-basin Eagle Creek smolts were released in the upper Yakima River at the Easton, Holmes and Stiles ponds on April $15^{\text {th }}$.

Table 1: Broodstocks, juvenile rearing facilities, and the number of PIT-tagged smolts released at the different locations (*mobile acclimation) for emigration years 2015 to 2019.

Unlike smolts, which begin emigration immediately after release, the released parr typically outmigrate as yearling smolts in the spring following their release. Therefore, PIT-tag data for parr releases was evaluated on the basis of emigration year (2015-2019). A total of 43,294 PIT-tag
detections (for parr) were retrieved for the 2019 migration year, corresponding to 9 locations in the Yakima Basin where parr were released in 2018 (Ahtanum Creek, Cowiche Creek, Little Naches River, Naches River, Rattlesnake Creek, Big Creek, Reecer Creek, Swauk Creek and Wilson Creek; Table 2, Figure 1C). The number of released parr that emigrated in 2019 was higher than other emigration years; no parr were released in 2016 thus there were no parr emigration data available for 2017 (Table 2).

Table 2: Number of parr-releases by migration year from 2015-2019. They were typically released one year earlier than the migration year.

### 2.3 Statistical analyses

Travel times and survival rates for both parr and smolt releases from the different release locations to McNary Dam were estimated each year from 2015 to 2019. Travel time was estimated as the difference between the date of release and the date of detection at McNary Dam. For data collected in prior years (2007 to 2018), a logistic regression model (see, Neeley 2012) was used to estimate survival. However beginning in 2019 and in this report, survival probability from release locations to downstream detection at McNary Dam and detection rate of the released PIT-tagged Coho smolts at McNary Dam were estimated using the Cormack-Jolly-Seber (CJS) mark-recapture model (see, White and Burnham 1999; Lebreton et al. 1992; Williams, et al. 2002, Conner et al. 2015), which has been commonly used within the Federal Columbia River Power System (FCRPS) to estimate survival rates for juvenile anadromous fish species (salmon and steelhead, see Tuomikoski et al. 2013). The model uses multiple detections of individually marked fish at several dams with PIT-tag detection capabilities (i.e. antenna arrays).

Among the several assumptions of the CJS model, one assumption is no immigration or emigration during capture and recapture intervals (detection), which is valid in the hydrosystem because of necessary passage at several hydroelectric dams, and where fish behavior is relatively consistent as fish are moving in one direction over a relatively short period of time (see Conner et al. 2015). The CJS model was originally formulated to calculate time-interval survival of tagged animals by recapturing individuals and estimating their survival and recapture probabilities using maximum likelihood. A spatial form of the CJS model can be used for species that migrate uni-directionally, and are recaptured/detected within a discrete migratory corridor (Henderson et al. 2018, Burnham 1987). We used individual fish encounter histories to estimate the likelihood that a fish would survive and be detected at each tag receiver facility (e.g. dams; Lebreton et al. 1992). The CJS model was run for all smolts released at each location based on an encounter history constructed from the
number of fish released at the different locations and subsequent detection events at McNary and Bonneville (BON) Dams. Similar to previous studies (Neeley 2018), we estimated the survival rate and detection efficiencies for each release group and broodstock source.

Several environmental factors are known to influence downstream smolt survival, and river flow is among the most impactful (Raymond 1968; Connor et al. 2003; Tiffan et al. 2009). Since early and late release groups presumably experience variable flow regimes in the Yakima River, each is likely to incur a different rate of survival associated with temporal river conditions. Therefore, it was necessary to introduce river flow and release month as covariates in the CJS model to estimate the survival rate of the releases. In the model we used the last five years of data (2015-2019) to increase the overall sample size and confidence around our estimates. Fish releases began in February and continued through May each year (2015-2019); however, in 2015, a drought year, only 6 PIT-tagged fish were released in May and this is not a sufficient sample size to estimate survival for the month. Therefore we excluded these 6 tagged fish and evaluated the effects for only three months in 2015 (Feb, March and April).

River flow data were accessed from the Bureau of Reclamation (BOR) website at: https://www.usbr.gov/pn/hydromet/yakima/yakwebarcread.html. The average travel time from Prosser to McNary Dam was approximately 20 days. Accordingly, river flow data were averaged for 20 day intervals. For example, a fish that was detected at Prosser Dam on April $1^{\text {st }}$ would reach McNary Dam about April 20 ${ }^{\text {th }}$, and the 20 day moving average flow rate for that time period would be assigned for that fish to determine the effect of river flow on survival rate.

Several candidate CJS models were built using every possible combination of river flow and release month, with varying or constant survival and detection probabilities at dams in the CJS models. To determine the rank of the different candidate models we used the difference in QAICc score ( $\triangle \mathrm{QAICc}$ ) relative to the top model. For models with $\Delta \mathrm{QAICc}<2$, we selected the model with the lowest QAIC and fewest parameters as the best model (Burnham and Anderson 2002). Selecting the best model, we estimated the effect of river flow on downstream survival rate for each release group. The CJS models were run within the RMark package (Laake and Rexstad 2019) in R statistical software, version 3.3.6 (R Core Team 2019).

## 3. Results and Discussion

### 3.1. Fish size (Fork length) at the time of tagging and release

Among the 97,553 smolts released with PIT-tags during 2015-2019, length data were available for only 8545 fish ( $5 \%$; Table 3). Juveniles from three broodstock sources (in-basin Yakima-stock, Eagle Creek and Washougal out-of-basin stocks) were released in the Yakima Basin in 2015-2019. Some fish were released in late February in 2017 (2/28/2017), but most of the fish were released in March and April. Overall, there was no significant difference in mean smolt fork length among release groups in different months except in 2015 (see figure 2). Fish that were tagged/released in May were the largest, but fish released in March tended to be larger at tagging than fish in the April release groups. This was contrary to expectations since fish should be growing larger over time. This observation was most likely a hatchery effect as March releases were largely comprised of fish reared at the Prosser hatchery where water temperatures are relatively higher compared to the other hatcheries used for rearing Coho juveniles released in the Yakima reintroduction program.

Two outplant stocks (Yakima and Eagle Creek) were released in 2019. Smolt releases began in February at the Ahtanum Creek location (2/21) and the last fish were released in Wenas Creek on April $23^{\text {rd }}$. Altogether 20,305 smolts were released at six locations. Smolts released from the Easton rearing site ranged in size (fork length) at tagging from 71 mm to 188 mm (average 100.20 mm ), whereas smolts reared at Holmes and Stiles ponds ranged in size from 67 mm to 126 mm (combined average 101 mm , see table 3 and figure 2). The difference in size of smolts at the rearing sites was not significant among the release groups at the different release locations during 2019.

Figure 2. Fork length (mm) of smolts at the time of tagging by release location, release month and year (2015-2019).

Table 3: Smolt fork length by release location, release month, and year: sample size ( N ), average fish size (mean), standard error (SE), range (minimum and maximum) Note: information is based on limited data available in PITAGIS ( $\mathrm{n}=8545$ out of 97553 total tags).

|  | Released |  | Mean |  |  |  | Range |  |

### 3.2. Detection rate of the smolt releases at McNary Dam

A total of 234, 1028, 474, 427 and 192 fish were detected at McNary Dam from 2015, 2016, 2017, 2018 and 2019 release groups, respectively (Figure 3 and table 4). The detection period (range of dates) varied among years. For example, during 2015 McNary dam detections were most numerous in early April and May, whereas in 2017 smolts were first detected on April $07^{\text {th }}$, with the last detection occurring on June $6^{\text {th }}$ (May $7^{\text {th }}$ average detection day; Figure 3). Similarly, in 2019 fish released in the Yakima River were first detected at McNary Dam on April $1^{\text {st }}$ with the last on June $4^{\text {th }}$ (Figure 3)

Table 4: Detection history (number of fish detected/not detected at McNary and Bonneville dams) and survival rate during out-migration of smolt release groups (A) and parr release groups (B) during the period 2015-2019. Enumeration of fish fate (Release/detection histories) is coded by detection (1) and no detection (0): "1.0.0." - no juvenile detection after release, "1.0.1" - not detected at McNary Dam but detected at Bonneville Dam, "1.1.0" - detected at McNary Dam but not at Bonneville Dam, and "1.1.1" - detected at all dams.
A. Smolt releases

| Released/Detection | 2015 | 2016 | 2017 | 2018 | 2019 |
| :--- | :---: | :---: | :---: | :---: | :---: |
| No detection after release (1.0.0) | 18167 | 23128 | 13601 | 18356 | 19775 |
| Detected at BON Dam but not at McNary Dam (1.0.1) | 392 | 621 | 337 | 483 | 338 |
| Detected at McNary Dam but not at BON Dam (1.1.0) | 179 | 825 | 431 | 379 | 168 |
| Detected at all Dams (1.1.1) | 55 | 203 | 43 | 48 | 24 |
| Total detected at McNary Dam | 234 | 1028 | 474 | 427 | 192 |

| Survival rate (\%) | 10.12 | 16.84 | 29.06 | 24.51 | 14.27 |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Standard Error of the Survival rate ( $\pm$ SE $)$ | 1.14 | 0.09 | 3.40 | 3.20 | 2.64 |

B. Parr releases (released parr typically outmigrate as yearling smolts)

| Released/Detection | 2015 | 2016 | 2017 | 2018 | 2019 |
| :--- | :---: | :---: | :---: | :---: | :---: |
| No detection after release (1.0.0) | 28547 | 25473 | 20614 | 41175 |  |
| Detected at BON Dam but not at McNary Dam (1.0.1) | 19 | 41 | 333 | 30 |  |
| Detected at McNary Dam but not at BON Dam (1.1.0) | 41 | 283 | 260 | 69 |  |
| Detected at all Dams (1.1.1) | 4 | 18 | 37 | 1 |  |
| Total no. of detection at McNary Dam | 45 | 301 | 297 | 70 |  |
| Survival rate (\%) | 0.90 | 3.82 | 13.98 | 5.26 |  |
| Standard error of the Survival rate ( $\pm$ SE) | 0.39 | 0.74 | 2.05 | 5.13 |  |

Note: there was no parr release during 2016 (migration year 2017)

Release groups from 2016 had the highest rate of detection at McNary Dam ( $25.06 \% \pm 1.27 \%$ ), whereas the lowest detection rates were observed among 2018 ( $9.25 \% \pm 0.9 \%$ ) and 2019 $(9.96 \% \pm 1.31 \%)$ release groups. The overall smolt detection rate at McNary Dam in 2019 was $9.96 \% \pm 1.31 \%$, which was similar to the detection rate of 2018 ( $9.25 \% \pm 0.9 \%$ ). Inter-annual variation in detection rates may be due to differences in river discharge, spillway discharge, water temperature, and other factors.

However, among the smolt release groups only within 2019, the detection rate for smolts was highest for the Prosser release group ( $20.28 \% \pm 2.7 \%$ ), followed by Easton ( $5.94 \% \pm 2.3 \%$ ), Jack Creek and Stiles ( $4.76 \% \pm 4.6 \%$ ), Holmes ( $0.2 \% \pm 0.08 \%$ ), Ahtanum Creek ( $0.01 \% \pm$ NA $\%$ ), and Wenas Lake ( $0.03 \% \pm 0.02 \%$ ) groups. No McNary Dam detections were observed for release groups from Wenas Creek above and below Wenas Lake (see Figure 4).

Figure: 3. Number of Coho smolt detections at McNary Dam for Yakima Basin release groups each year (from 2015 to 2019).

Figure 4. Number of PIT-tag detections at McNary and Prosser Dams for the different release locations of the Yakima basin in 2019. The left panel represents out-of-basin Eagle Creek smolts (Eagle Creek), whereas the right panel represents the in-basin Yakima (Yakima) stock. The information given in each row is the average travel time (mean days $\pm$ SE) from release locations to Prosser and McNary Dams.

The study further found that McNary Dam detection rates were generally lower for fish released from upper Yakima River locations in May and June (see figure 5). This is likely due to higher mortality associated with lower river flows and/or increasing water temperature in the lower Yakima

River during those months (further investigation is warranted). Flows typically decrease beginning in the first week of May as runoff declines and irrigation diversions increase in the basin.

Figure 5. Coho smolt detections at Prosser (blue bar) and McNary Dam (red bar), water temperature in degrees Celsius (dotted red line) in the Lower Yakima River and river flow near Prosser Dam. [Note: water temperatures were averaged between measurements at Benton City and Lower Yakima sites obtained from the Yakama Nation's Lower Yakima Predation study. For days with no temperature measurement a linear average value was estimated.. River flow was standardized using a square root transformation.]

In general the Yakima-stock releases had a higher detection rate at McNary Dam (11.27\% $\pm 1.34 \%$ ), compared to the Eagle Creek stock releases in $2019(2.94 \% \pm 1.02 \%$; tables 4 and 6, figure 4). This is presumably due to a higher detection rate at McNary Dam for the Prosser releases, which were the farthest downstream in the Yakima River and nearest McNary Dam. Release groups farther
upstream in the Yakima River must travel a greater distance, with an associated higher risk of mortality (e.g. predation), resulting in a reduced detection rate at McNary Dam.

### 3.3. Detection rate of parr releases at McNary Dam

Similar to smolt releases, detection rates at McNary Dam for parr releases were variable among years (table 4, figure 6). Few McNary Dam detections were observed for parr releases compared to smolt releases. Only 45, 301, 297,70 PIT-tagged parr were detected at McNary Dam from the outmigration year 2015, 2016, 2018 and 2019 release groups, respectively (released parr typically outmigrate as yearling smolts). On average, for the 2015-2019 migration years parr were detected at McNary Dam 320 days following release, ranging from a minimum of 200 days to a maximum of 700 days (Figure 7). Interestingly, 11 fish were detected at the McNary Dam juvenile facility moving downstream after spending almost 2 years in freshwater (Table 5, Figure 7). This case was not only in the Yakima River; Moyle (2002) also reported that although most coho salmon smolts leaving California streams reportedly are 12 to 15 months old, some juveniles reportedly stay in the stream 2 years before emigration (Moyle 2002).

Figure: 6. Smolt detections at McNary Dam by date (month/day) for fish released as parr (migration years 2015-2019)

Figure 7. Detection history: total days between parr release date in the Yakima river and detection date at McNary Dam. The red oval is showing the number of fish that were detected at McNary Dam after 650 days from the date of release (also see Table 5 and ).

Table 5. Downstream migration date and first downstream detected site (McNary or John Day Juvenile Fish Bypass/Transportation facilities) for 11 fish that spent nearly two years in freshwater after release (also see Figure 7).

| Tag Code | Release Date | Release Site | $\begin{aligned} & \text { Migration } \\ & \text { Year } \\ & \hline \end{aligned}$ | Detected at |  | Days After Release |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

### 3.4. Travel Time from Release Locations to McNary Dam

Results indicated variable travel times to McNary Dam for smolts released at the different locations, ranging from 33 to 47 days (excluding the Prosser Dam releases; Table 6.A). Fish released at Prosser Dam exhibited the shortest travel time to McNary Dam (mean $21.32 \pm 8.54$ days), whereas the Jack Creek release group (the farthest upstream site) had the longest travel time (mean $47.14 \pm 4.59$ days). Mean travel times for the groups released at Easton, Holmes, Stiles, Wenas Lake, and Ahtanum Creek ranged from 33 to 39 days. The travel time often depended on distance (how far is the release location from the dam) and also release month (February, March or April). The fish that were released earlier took more time to travel than the fish that were released later. River flows also affected travel time, but further detailed monitoring is warranted to better understand the unique effects (contributions) of river flow and release month on the travel time. If the Prosser release group is excluded from the analysis, there was no significant difference in travel time between Eagle Creek stock and Yakima-stock releases (table 6.A). For the 2018 parr releases (migration year 2019), the ranged of travel time was from 208 days (the population released at Ahtanum creek) to 316 days (population released at Cowiche Creek, see table 6.B.).

Table 6. Travel time from release site to McNary Dam for [A] smolt releases in 2019, and [B] parr releases in 2018 (migration year 2019).

## A. Smolt releases

| Stock | Released site | Average travel days $\pm$ SE |  |
| :--- | :---: | :--- | :--- |
| Eagle | $\bullet$ | Easton Pond | $38.98 \pm 6.32$ |
| Creek | $\bullet$ | Holmes Pond | $33.32 \pm 4.04$ |
|  | $\bullet$ | Stiles Pond | $35.61 \pm 5.11$ |

|  | $\bullet$ | Wenas Cr. above Wenas Lake | $*$ |
| :--- | :--- | :--- | :--- |
|  | $\bullet$ | Wenas Cr. below Wenas Lake | $*$ |
|  | $\bullet$ Wenas Lake at Upper Boat Launch | $34.78 \pm 0.58$ |  |
|  | $\bullet$ Ahtanum | $36.50 \pm 4.44$ |  |
| Yakima | - Prosser | $21.32 \pm 8.54$ |  |
|  | $\bullet$ | Jack creek Acclimation site | $47.135 \pm 4.59$ |
|  |  |  |  |

*Indicates the fish released at that location were not detected at McNary Dam.

## B. Part releases

| Parr_release_site | Average | SE | Min | Max |
| :--- | ---: | :--- | :---: | :---: |
| $\bullet$ | 209.33 | 4.81 | 200 | 216 |
| - AHTANC - Ahtanum Creek | 307.25 | 1.55 | 303 | 310 |
| - COWICC - Cowiche Creek | 316.50 | 3.50 | 313 | 320 |
| - LTNACR - Little Naches River | 304.50 | 6.50 | 298 | 311 |
| - NATCHR - Naches River | 308.50 | 1.43 | 301 | 317 |
| - RSNAKC - Rattlesnake Creek | 300.63 | 4.97 | 280 | 314 |
| - | REECEC - Reecer Creek | 310.71 | 2.06 | 301 |
| - SWAUKC - Swauk Creek | 312.00 | NA | 312 | 312 |
| - TIETNR - Tieton River | 296.58 | 3.12 | 276 | 310 |
| - WILSNC - Wilson Creek | 308.80 | 1.67 | 300 | 317 |
| - YAKIM2 - Yakima River above Naches River | 302.17 | 1.22 | 300 | 308 |

### 3.5. Survival Probability (Release Site to McNary Dam)

## A. Annual survival probability of smolt and part releases by migration year

The average survival probability of Coho Salmon smolts from the release sites to McNary Dam in 2019 was $14.27 \pm 2.64 \%$, which was lower than both the 2017 estimate ( $29.1 \pm 3.4 \%$ ) and 2018 estimate $(24.5 \pm 3.2 \%)$, but higher than the 2015 estimate ( $10.1 \pm 1.14 \%$, see Figure 8$)$. The study showed that the average survival probability from the release site to McNary Dam varied among years. In general, downstream smolt migration survival depends on several environmental factors such as water temperature and river flow (Scheuerell et al. 2009; Petrosky and Schaller 2010; Haeseker et al. 2012), which are highly variable among years in the Yakima Basin. For example, in 2015 there was an extremely low snow pack and an early snowmelt, which would have affected flow rate and water temperature. In-stream conditions may have contributed to the poor smolt-to-smolt survival observed in that year. Similarly, the flows during summer were relatively low in 2019
compared to 2017 and 2018 (see figure 11 and table 12), which may be related to the higher survival probability of smolts in those years.

The parr-release groups, which overwintered in freshwater before outmigration, experienced a lower rate of survival compared to that of the smolt-release groups each year (Figure 8), however the interannual variation of parr-release survival rates also corresponds with the variation of the survival rate of smolt-release groups. For example, survival of parr releases was highest in 2017 (among 2015, 2016, 2018 and 2019), similar to the inter-annual variation for the smolt release groups, which suggests that the survival rate for both groups might have been affected by common factors (e.g., higher temperature or river flow).

Figure 8. Overall smolt survival rate ( $\pm \mathrm{SE}$ ) from release site to McNary Dam for the smolt and parr release groups, migration years 2015-2019.

## B. Comparison of Survival probability among broodstocks (in-basin and out-ofbasin)

The average survival rate (2015-2019) for smolt releases differed among the stocks (Yakima-stock releases and out-of-basin Eagle Creek-stock and Washougal-stock releases. The survival rate was highest for the Yakima-stock releases ( $17.51 \pm 0.8 \%$ ), followed by Eagle Creek-stock releases ( 15.04 $\pm 2.4 \%$ ) and Washougal-stock releases ( $8.49 \pm 1.6 \%$ ). In 2019, when there was no release of the Washougal stock, the survival rate was slightly higher for the Yakima stock compared to the Eagle Creek stock (Tables 7 and 8).

## C. Survival probability of smolt and parr releases by release locations

## C.1. Smolt releases

In each year from 2015 to 2019, smolts released at the Prosser site had the highest survival among all Yakima River sites ( $37.2 \%$ in 2015; 22.9\% in 2016, $66.5 \%$ in 2017, $97.9 \%$ in 2018 and $25.11 \% \pm$ $2.98 \%$ in 2019; Table 7). Annual survival rates for the Yakima-stock released at Prosser and Stiles ranged from a low of $22.9 \%$ in 2016 to a high of $97.8 \%$ in 2018 (Tables 8, Figure 9). The high survival estimate for 2018 may be due to low estimated detection efficiencies for that release group, which will need to be verified.

Table 7. Survival probability (from the release location to McNary) for the smolt releases from 2015 through 2019. For 2019 results, average survival rate and its standard errors are also given (mean $\pm$ SE). "NA" represents survival rate was not able to estimate due to the model convergence issue (not enough detections at downstream dams).

| Stock | Release site | 2015 | 2016 | 2017 | 2018 | 2019 |
| :--- | :--- | :---: | :---: | :---: | :---: | :---: |
|  | • Stiles | $8.20 \%$ | $24.70 \%$ | $27.40 \%$ |  |  |
|  | • Prosser | $37.20 \%$ | $22.90 \%$ | $66.50 \%$ | $97.90 \%$ | $25.19 \pm 2.98 \%$ |
|  | • Easton |  | $13.30 \%$ |  |  |  |
|  | $\bullet$ Buckskin Slough | $20.40 \%$ |  | $24.10 \%$ |  |  |
|  | $\bullet$ South Fk Cowiche Creek |  |  | $25.30 \%$ |  |  |
| Yakima | • Ahtanum Creek |  |  | $0.88 \pm 0.68 \%$ |  |  |
|  | • Jack Creek |  |  | $6.01 \pm 3.58 \%$ |  |  |
|  | • Wenas Lake above Wenas |  |  | $0.25 \pm 1.18 \%$ |  |  |
|  | Dam (Wenas wildlife area) |  |  | NA |  |  |

- Wenas Lake at Upper Boat

| Launch |  | $1.59 \pm 1.18 \%$ |  |
| :---: | :---: | :---: | :---: |
| • Stiles | $25.50 \%$ | $16.83 \pm 6.86 \%$ |  |
|  | $\bullet$ Easton | $9.20 \%$ | $17.21 \pm 8.03 \%$ |
| Eagle Creek $\bullet$ Holmes |  | $6.51 \pm 4.09 \%$ |  |
| Washougal $\bullet$ Prosser | $32.10 \%$ |  |  |

Note: Estimates for the years 2015-2018 were adopted from Neeley (2018). For 2019, it was found that some of the fish that was releases at different locations was not detected at McNary but it was detected at JohnDay Dam, therefore the survival rate was estimated using the joined detections events of McNary Dam and JohnDay.

Among eight release locations in 2019 (Yakima and Eagle creek stock releases) the Prosser group (below Prosser Dam) had the highest survival rate $(25.19 \% \pm 2.98 \%)$ and the lowest survival was for the group released at Wenas lake (Wenas wildlife area) (Tables 7, Figure 9).

Figure 9. Survival probability (release site to McNary Dam) of the group released as smolt in 2019 (outmigration year 2019).

Release location and Brood stocks

## C.1.1. Annual comparison of survival rate release at PROSSER

As shown above, the juvenile outmigration survival rate from the release location to McNary Dam varied by release locations. Prosser release was the highest among the groups that were released at the different locations, however this was also varied among years. The highest estimated survival rate for the group was found to be in 2018, but as mentioned above the survival rate ( $97.9 \%$ ) survival seemed not be an accurate estimate (See Table 8). It might be either due to low detection rate at the downstream Dams or methodological errors. When looking at the annual trend except 2018, the highest survival rate was in 2014 ( $78 \%$ ), whereas the lowest in 2016 ( $22.9 \%$, see table 8 ).

Table 8. Survival to McNary Dam for fish released at the Prosser site for all years in which the Yakima stock was released. Average survival rate (mean $\pm$ SE) is shown only for the 2019 release.

| Year | Number released | Release Date | Travel days <br> $($ Mean $\pm$ SE) | Survival Probability <br> (Mean $\pm$ SE) |
| :---: | :---: | :---: | :---: | :---: |
| 2007 | 2499 | $4 / 15$ | 15 | 62.7 |
| 2008 |  |  |  |  |
| 2009 | 2506 | $4 / 2$ | 41 | 65.7 |
| 2010 | 1371 | $4 / 4$ | 24 | 52.5 |
| 2011 | 5036 | $4 / 15$ | 30 | 37.6 |
| 2012 | 3811 | $3 / 5$ | 58 | 33.9 |
| 2013 | 2520 | $4 / 15$ | 8 | 67.2 |
| 2014 | 3004 | $4 / 14$ | 18 | 78.0 |
| 2015 | 1265 | $3 / 23$ | 21 | 37.2 |
| 2016 | 2501 | $4 / 4$ | 19 | 22.9 |
| 2017 | 2876 | $3 / 19$ | 34 | 66.5 |
| 2018 | 2509 | $3 / 14$ | 48 | 97.9 |
| 2019 | 2533 | $4 / 2$ | $21.32 \pm 8.54$ | $25.19 \pm 2.98$ |

Note: Estimates for the years 2015-2018 were adopted from Neeley (2018)

## C.1.2. Annual comparison of survival rate release at STILES

Similar to Prosser, the survival rate (release site to McNarry dam) of the group released at Stiles also varied by years. Last two years, the fish were not released from that location (see Table 9).

Table. 9. Survival from release to McNary Dam for the Yakima stock released at the Stiles location.

| Year | Number released | Release Date | Travel days <br> (Mean $\pm$ SE) | Survival Probability <br> (Mean $\pm$ SE) |
| :---: | :---: | :---: | :---: | :---: |
| 2001 | 1240 | $5 / 17$ | 22 | 43.2 |
| 2002 |  |  |  |  |
| 2003 | 1249 | $5 / 7$ | 14 | 40.0 |
| 2004 |  |  |  |  |
| 2005 |  | $4 / 3$ | 38 | 32.7 |
| 2006 | 2490 | $4 / 5$ | 41 | 25.0 |
| 2007 | 2449 |  |  |  |
| 2008 |  | $4 / 15$ | 36 | 47.6 |
| 2009 | 2515 | $4 / 12$ | 36 | 18.7 |
| 2010 | 2501 |  |  |  |
| 2011 |  | $4 / 16$ | 32 | 38.0 |
| 2012 | 2526 | $4 / 15$ | 30 | 44.2 |
| 2013 | 2504 | $4 / 16$ | 25 | 44.9 |
| 2014 | 2505 | $3 / 23$ | 51 | 08.2 |
| 2015 | 2520 | $4 / 7$ | 35 | 24.7 |
| 2016 | 3768 | $4 / 17$ | 31 | 27.4 |
| 2017 | 5007 |  |  |  |
| 2018 | NO RELEASE |  |  |  |
| 2019 | NO RELEASE |  |  |  |

Note: Results from 2007 to 2018 were adopted from Neeley (2018)

In general, the survival rate of the both groups released at Prosser and Stiles were varied by years; and the Prosser release groups had a higher survival rate than the Stiles group (Figure 10). However,
during 2012 and 2016, the smolt outmigration survival rate of Stiles was relatively higher survival rate of the group released in Prosser (Figure 10).

Figure 10. Bar plot showing survival to McNary Dam for the Yakima stock released at Prosser from 2007 through 2019 (red color) and from Stiles (green color) from 2001 through 2019. The 2019 results include average survival rate (mean $\pm$ SE).

## C.2. Parr releases

Parr survival varied broadly among years, and the average survival rate for parr releases in the Yakima basin was lower than the average survival rate from smolt releases (see, Figure 8). On average, the survival rate for the migration year 2019 was $\sim 5 \%$ (see Figure 8), with the highest survival rate observed among releases from the Rattlesnake Creek and the lowest survival rate for the Big Creek site and South fork Cowiche (less than 1; Table 10). Survival rate (from Swauk Creek to the McMaster) was also low ( $0.13 \%$ ) but its standard Error was very high $(75.53 \%)$, which indicates that a very few fish were detected at the downstream Dams (table 10, Figure 11). It is therefore recommended to release more PIT tags fish, which can help to reduce bounds of the average survival rate.

Table 10. Survival probability (from the release location to McNary) for the parr releases in 2018 (outmigration year 2019). "NA or *" represent survival rate was not able to estimate due to the model convergence issue (not enough detections at downstream dams).

|  | Survival Probability |  |
| :--- | :--- | :--- |
| Released Location | Mean (\%) | SE (\%) |
| Ahtanum Creek | 4.71 | 1.06 |
| Rattlesnake Creek | 15.25 | 5.07 |
| Big Creek | 0.40 | 0.15 |
| Naches River | 4.78 | 4.42 |
| Easton Reach | NA |  |
| SF Cowiche Creek | 0.40 | 0.28 |
| Reecer Creek | 2.56 | 1.10 |
| Swauk Creek | 0.13 | $75.53^{*}$ |
| Tieton River | 9.16 | 8.60 |

## D. Effect of river flow and release month on survival rate

One of the objectives of these monitoring efforts was to evaluate the effects of river flow on outmigration survival rate, and to determine whether the effect differed as a function of release month (February, March and April). Data showed that the average river flow measured below Prosser Dam during April of 2019 was approximately 4,444 cubic feet per second (cfs), which was higher than the average flow in April 2015 but slightly lower than the average April flows in both 2016 and 2017 (Figure 12, table 12). In general the river flow from June to September (2015-2019) was considerably lower ( 800 cfs ) than April and May observations. Summer flow below Prosser Dam is maintained by reservoir releases to protect aquatic life, but target flows can vary according to how much water remains in storage.

Figure 12. Average daily Yakima River flow (cfs; blue line) and 20-day average flow (smoothed yellow line) measured near Prosser Dam from January to December (2015-2019). The boxes (red border) highlight the time period when fish were being released at different locations.

Table 12. Average monthly Yakima River flow (cfs) measured below Prosser Dam (gauging station YRPW).

|  | Month |  |  |  |  |  |  |  |  |  |  |  |
| :---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| Year | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 |
| 2015 | 4793 | 4420 | 2523 | 1043 | 895 | 420 | 387 | 526 | 581 | 892 | 3549 | 5237 |
| 2016 | 2632 | 8603 | 7982 | 8600 | 3437 | 983 | 822 | 519 | 517 | 2086 | 2582 | 1920 |
| 2017 | 1696 | 3460 | 9492 | 8778 | 6959 | 2697 | 640 | 666 | 657 | 1463 | 3585 | 2434 |
| 2018 | 3038 | 4138 | 2632 | 5183 | 6183 | 994 | 574 | 604 | 542 | 1054 | 1489 | 1775 |
| 2019 | 1389 | 1536 | 3066 | 4444 | 1860 | 563 | 560 | 749 | 568 | 1041 | 1458 | 2122 |

A CJS model was used to evaluate the effect of river flows on outmigration survival rate as a function of release month (February, March and April). Among several candidate models considered (Table 13), the model with river flow and release month was the most parsimonious (Table 13); the best competing model was $\varphi(\sim$ Dam:Year:month + RF $)$ p $(\sim$ Dam:Year:month + RF $)$. Based on the best CJS models that included river flow and release months as covariates (the model with the lowest QAICs), we observed a positive correlation between flow and survival rate (survival increased as flow increased) for all months (February, March or April). The highest survival rate was found for the March release group, followed by April releases, and lastly February releases (Figure 12). Since Prosser was the only location with releases in each month, we could not compare the effect of release time (months) for all release groups across all locations. Survival rates among years at the Prosser location (See Figure 13) were highest for the March release groups. However, the sample size for February releases was comparatively small ( $4 \%$ of total releases) compared to March releases (45\%) and April releases (51\%).

Table 13. Candidate CJS mark-recapture models to determine the effect of river flow and release months for the survival parameter $(\varphi)$; various effects were modelled for $\varphi$ using release time ("month") and river flow ("RF").

Figure 13. The relationship between survival probability (Release location to McNary Dam) and the river flow at Prosser Dam for the smolt release groups each month. The relationship was devolved using the last five years smolt PIT-tag data (2015-2019).

## E. Effect of release month on parr survival rate

Parr were released at the different locations from May to October (Table 14, Figure 14). Survival from release to downstream detection at McNary Dam (outmigration years 2015-2019) was highest
among parr released in August ( $14 \% \pm 0.020$ ), followed by parr releases in July ( $3.1 \% \pm 0.40$ ) and June ( $1 \% \pm 0.4$ ). Lower survival rates for groups released in May and June are likely due to mortality associated with longer exposure to summer conditions. Water temperature increases in most river sections during summer while parr are rearing. In the summertime, coho salmon fry reportedly prefer water temperatures of $50^{\circ} \mathrm{F}$ to $59^{\circ} \mathrm{F}\left(10^{\circ} \mathrm{C}\right.$ to $15^{\circ} \mathrm{C}$; Reiser and Bjornn 1979), while higher temperatures may cause greater mortality in the parr life stage.

Table 14. Total number of PIT-tagged parr released among the different locations in the Yakima Basin, and survival rate (to McNary Dam) for each migration year from 2015-2019.

|  | Parr release months and number of parr with PIT Tags |  |  |  |  |

## 4. Acknowledgment

We thank all of the crews whose collective fish-tagging efforts over the years made this study possible. We are also grateful to Andrew Matala and David Lind who reviewed, edited and provided valuable comments in the draft report. We would also like to thank Daylen Isaac who provided the hydrological data.

## Executive Summary

Summer-run Chinook salmon were once widely distributed in the Yakima River basin but were extirpated by the 1970s. Since 2009, building on habitat, passage and instream flow restoration efforts, the Yakama Nation has been implementing a reintroduction program, in which summer chinook eggs are brought from Upper Columbia Basin hatcheries to the Yakama Nation's Marion Drain Hatchery for fertilization, incubation and rearing. Subyearling/presmolts are moved from the hatchery to permanent and mobile acclimation sites upriver for release as smolts into different areas of the Yakima basin. Diverse release strategies, such as releasing from different locations and experimenting with different release dates, have been utilized to maximize the likelihood of achieving stable and abundant returns of natural-origin Summer Chinook to the Yakima River basin and to enhance the stability and resiliency of the population against potential environmental changes.

In 2019 a total of 806,000 subyearling Summer Chinook were released, with 41,143 (about $5 \%$ of the total release) tagged for monitoring purposes, especially to evaluate juvenile survival rates and release strategies. This evaluation is an update of ongoing annual monitoring that was initiated with the first reintroductions in 2009. The main objectives of the study are to estimate survival rate of the fish released from each location in the Yakima Basin in 2019 and compare the results with previous years' results to evaluate success and discern trends. We further evaluate whether juvenile survival rate is higher in one release location than other or whether the survival rate is a function of release location, release year and month, river flow, size of released fish, or interactions among variables. For data collected in prior years (2009 through 2018), a logistic regression model (Neeley 2012) was used to estimate survival. For the 2019 releases, survival probability from the release locations to downstream dams and detection rate at Prosser and McNary Dams were estimated using the Cormack-Jolly-Seber (CJS) mark-recapture model, along with other statistical analysis of travel time and the effect of river flow to answer the following research questions:

## - What was the detection rate of juvenile summer chinook at Prosser Dam and McNary Dam, and do the detection rates vary by year? If there is an annual variation in the rate of detection, what factors cause this variability?

The average rate of detection at McNary Dam for the 2019 PIT-tag release was found to be $7.22 \%$ ( $\pm 1.36 \%$ ); whereas the detection for the fish at Prosser Dam was $43.75 \%$ ( $\pm 6.23 \%)$. Over the years 2009-2019, detection rate varied, and was lowest in 2015, due to poor river conditions in that year.

Annual variation can be due to many factors besides river conditions, such as what proportion of fish pass dams via juvenile bypass systems where detectors are installed. As spill has been increased to improve survival of juvenile fish passing dams within the Federal Columbia River Power System, a lower proportion of outmigrants enter juvenile bypass systems where PIT tags can be detected, and variations in spill percentage can make the detection rate vary among years or even from day to day.

- What was the juvenile survival rate from the release sites to McNary Dam of each of the groups released to different streams during 2019?

In 2019, the overall juvenile outmigration survival rates from release to Prosser Dam and from Prosser to McNary Dam were $44.8 \% \pm 4.0$ and $16.9 \% \pm 3.3$, respectively, so that survival rate of the Summer Chinook in 2019 from the release to McNary was $7.6 \% \pm 1.3 \%$. Fish were released at four locations in 2019, and survival rates varied among release locations, ranging from $38.7 \% \pm 2.9 \%$ to Prosser for the group that was released at Roza, to $0.15 \% \pm 0.14 \%$ to Prosser for the Wapatox release group. Among the releases of these four locations, highest survival rate from the released locations to McNary Dam was $17.9 \% \pm 3.7 \%$ for the group released just below Prosser Dam, the second highest was for the group released at Roza Dam ( $11.0 \% \pm 4.2 \%$ ), followed by the Buckskin Slough group at $2.3 \% \pm 2.1 \%$. There were no detections of the Wapatox group at or below McNary Dam, thus no survival rate for that group.

- Did the survival rate vary by year from 2009 through 2019, and among the groups released in different locations?

Survival rates varied by year over the period from 2009 through 2019. The highest average annual survival rate was in $2011(40.15 \% \pm 1.94 \%)$ and the lowest was in $2015(0.73 \% \pm 0.47 \%)$. For 2019, the average survival rate from the combined release locations to McNary Dam was $7.22 \% \pm 1.35 \%$, which was higher than 2018's overall survival rate ( $2.58 \% \pm 0.41 \%$ ).

Overall survival rates for the period 2009 through 2019 varied among release locations as well. The highest survival rate from release to McNary Dam was for the group released from Stiles Pond ( $20.3 \% \pm 11.03 \%$ ) and the second highest survival rate was for the Buckskin Slough group ( $19.2 \%$ $\pm 6.81 \%)$. The lowest survival rate was for the group released from Wapatox Dam ( $0.15 \% \pm 0.14 \%$ ).

- If survival rates varied by year, was the variation in survival rate correlated with variation in river flow?

Yes, the relationship between the average of May and June river flow measured below Prosser Dam and the annual survival rate (release location to McNary Dam from 2009 through 2019 was strong and statistically significant $\left(\mathrm{r}^{2}=0.45, \mathrm{p}=0.03\right)$ indicating that survival rate was a function of river flow in May and June. Higher flow in these months results in higher survival of juvenile Summer Chinook outmigrants.

- With smolts released in different months (April, May and June) to increase temporal distribution, was fish size different for different release dates? What was the effect of fish size and release month on survival rate from the release sites to Prosser Dam, and from Prosser Dam to McNary Dam?

There was an interaction effect between release periods (April, May and June) and fish size (fork length) on the juvenile survival rate for both segments (release site to Prosser Dam; and Prosser Dam to McNary Dam). Release period affected survival of small fish from release to Prosser Dam more than survival of large fish through the same reach. From Prosser to McNary Dam, the relationship of size to survival rate was similar for April and May releases, but release in June depressed the Prosser-to-McNary survival rate over the entire range of fish sizes.

- Did fish released earlier (April) enter the Columbia River estuary earlier (based on detections at Bonneville Dam) than fish released later (June), or did earlier outmigrants travel slower in order to prepare physiologically for saltwater, so that all groups entered the estuary near the same time regardless of when they were released?

The Summer Chinook releases generally exhibited immediate outmigration behavior after release, regardless of release date, but later outmigrants showed greater urgency. Travel days from Prosser Dam to Bonneville Dam for the groups released in April were $73.08 \pm 37.77$ days, whereas the fish released in June took only $32.70 \pm 9.89$ days to reach Bonneville Dam.

- What was the rate of rate of travel from Prosser Dam to Bonneville Dam of the groups released in April, May and June?

The rate of travel to Bonneville Dam was $7.19 \mathrm{~km} /$ day for the group released in April, but the rate of travel more than doubled ( $16.64 \mathrm{~km} /$ day) for the group released in June. This indicates that fish released earlier spent more time in the mainstem in order to go through the series of physiological and morphological changes that allow for a transition to life in salt water. The study suggests that regardless of when they were released, the Summer Chinook seemed to enter the ocean at nearly the same time, although outmigration survival rate was higher for the early release.

## 1. Introduction

The Summer Chinook (Oncorhynchus tshanytscha) is one of the three historical chinook runs in the Yakima River basin. Adults of the summer run first enter the Yakima River from the ocean in June, and the remainder of the summer run is shaped by flow and temperature in the lower Yakima River, which is strongly influenced by irrigation withdrawals and return flow. Unfavorable conditions can delay entry of the latter part of the summer run from the Columbia River until near the fall spawning season. Juvenile Summer Chinook typically leave the Yakima River from late spring to early summer of the year after spawning. Summer Chinook were once widely distributed in the Yakima and Naches rivers (Figure 1) but were extirpated from the Yakima basin by 1970. For decades, several programs such as habitat restoration and species reintroduction were implemented in the Yakima River. With improving spawning and rearing habitat conditions made possible by habitat and instream flow restoration, with improved juvenile and adult passage in the mainstem Columbia River, and with improved ocean conditions, reintroduced adult summer chinook, along with supplemented fall chinook, are returning to the Yakima basin. Annual abundance of summer/fall Chinook at Prosser Dam on the lower Yakima River has increased from an average of just over 1000 fish from 1983 through 1999 to over 4,300 fish on average during the period 20002018). We have successfully achieved some level of natural production and local adaptation, however it is still unstable.

Based on 2009-2019 release data, an annual average of 238,629 Summer Chinook juveniles were released in the Yakima basin (Table 1). Usually each year, eggs of the species are brought either from the Entiat or Wells hatchery (Entiat and Wells stocks) to the Yakama Nation's Prosser Hatchery for fertilization, incubation and rearing through the fall and winter. The following spring, subyearlings are moved to the acclimation sites upriver and are released directly from permanent acclimation sites on the Yakima and Naches rivers or from temporary mobile acclimation facilities operated on smaller tributary streams. Several release strategies have been utilized to maximize the likelihood of achieving stable and abundant returns of natural-origin Summer Chinook to the Yakima River and to enhance the stability and resiliency of the population against potential environmental changes. The strategies include releasing the juveniles into different tributaries (spatial variation) and also different months (temporal variation). Whether one release strategy performs better than other
strategies in terms of juvenile survival and smolt-to-adult return (SAR) are fundamental questions in determining whether species management and production goals are being reached.

On average each year about $12 \%$ of the total release is PIT-tagged as part of an ongoing, long-term monitoring program to help improve project objectives and strategies by applying what is learned from experimentation, monitoring, evaluation and literature reviews as an adaptive management framework. This evaluation is an update of ongoing annual monitoring that began with the first reintroductions in 2009.

In general juvenile survival rate often vary by seasons and years. This variation can be associated with rearing history and environmental conditions. For example, Zabel and Achord (2004) found that juvenile survival rate of wild salmonids was related to fish size (fork length), with larger juveniles having higher downstream survival. Similarly, survival rate increases as river flow increases. Although the Yakima River is highly controlled by storage reservoirs and irrigation and hydropower withdrawals, there is still a large variation in the flow pattern within and across years, which can affect the survival rate of juvenile salmon. Even the ocean-type summer and fall chinook, which naturally outmigrate from Columbia River tributaries in late spring and early summer, can be harmed by rising water temperature as they attempt to leave the Yakima Basin. Based on the effect of temperature, one can postulate that survival rate should be lower if the fish are released in later months, e.g. June, than fish released as early as April. However, individuals released earlier are likely to be smaller than fish released later and closer to natural outmigration timing. There may be an interaction between fish size and release timing on survival, but that has not been explored so far in the previous studies.

The primary objectives of the study are to explore the effect of release date and fish size on survival. More specifically, our objectives are to determine the survival rate from release sites to Prosser Dam or McNary Dam of groups released at different locations in the Yakima Basin during 2019; and understand how other factors (fish size and release date) affect juvenile survival rates using the last 10 years' data (2010-2009). The information is critical for recovery of depressed Chinook stocks.

To achieve these objectives, we focused on the following research questions:

- What was the detection rate of juvenile summer chinook at Prosser Dam and McNary Dam, and do the detection rates vary by year? If there is an annual variation in the rate of detection,
what factors cause this variability?
- What was the juvenile survival rate from the release sites to McNary Dam of each of the groups released to different streams during 2019?
- Did the survival rate vary by year from 2009 through 2019, and among the groups released in different locations?
- If survival rates varied by year, was the variation in survival rate correlated with variation in river flow?
- With smolts released in different months (April, May and June) to increase temporal distribution, was fish size different for different release dates? What was the effect of fish size and release month on survival rate from the release sites to Prosser Dam, and from Prosser Dam to McNary Dam?
- Did fish released earlier (April) enter the Columbia River estuary earlier (based on detections at Bonneville Dam) than fish released later (June), or did earlier outmigrants travel slower in order to prepare physiologically for saltwater, so that all groups entered the estuary near the same time regardless of when they were released?
- What was the rate of rate of travel from Prosser Dam to Bonneville Dam of the groups released in April, May and June?

## 2. Methodology

### 2.1. Geographical distribution: historical and current

Chinook (spring, summer, and fall runs) were native to the Yakima River basin and their historical spawning area was quite widespread in the basin (Figure 1A) but their spawning area has been reduced (Figure 1B). A major objective of the summer-run Chinook reintroduction program, begun in 2009, is to re-establish spawning in the primary historical spawning areas for this run, which are upstream of Wapato Dam to the Yakima River canyon above Roza Dam and from the confluence of the Tieton and Naches Rivers (Figure 1C). The uppermost acclimation and release sites designated in the reintroduction program were located to facilitate adult homing throughout this historical geographical distribution, while the lower sites (Marion Drain downstream to the river mouth) were chosen to maximize survival rates and improve opportunities to collect returning adults as we work to establish a localized brood source (Figure 1D).

Figure 1. Historical (A) and current (B) Summer Chinook spawning area; and the locations/tributaries/river segments where Summer Chinook juveniles were introduced from 2009 through 2019.

### 2.2. Brood stocks and fish data

Every year, eggs of summer Chinook have been brought to Yakima basin either from the Wells Hatchery which is located in Pateros, WA (especially for the years from 2008-2019) or Entiat Hatchery (2018-2019) or Wenatchee Stock from Eastbank Hatchery (2010) (See Figure 2). The adult fish were spawned at either Wells or Entiat; and green eggs and milt were transferred to the YN Prosser Hatchery for fertilization, incubation and rearing. Presmolt subyearling juveniles were
moved to five acclimation sites upriver (Stiles Pond, Buckskin Slough, Marion Drain, Roza Dam and Wapatox Diversion).

On average 32,570 juvenile Summer Chinook were PIT-tagged per year (the range was 49,894 in 2011 to 17,539 in 2017) prior to release between April and June (Figure 2), directly from the acclimation sites listed above or from temporary mobile acclimation facilities operated in upstream locations in tributary streams of the Naches and Yakima rivers (Table 2, Figure 1.D). In 2019, a total of 806,000 subyearling summer Chinook were released from the Buckskin, Roza and Wapatox sites, along with a group released directly from Prosser Hatchery, including 41,152 fish with PITtags (Table 1), all within a week between May $13^{\text {th }}$ and May $19^{\text {th }}, 2019$ (Figure 2).

Table 1. Total release of Summer-Chinook run (with and Without PIT-tags) and the percentage of PIT-tag. Total release by released location can be found figure 2.

|  | Total Release |  |  |
| :---: | :---: | :---: | :---: |
| Year | Total release (with \& without PIT-tag) | With PIT-tag | PIT-tag Percentage (\%) |
| 2009 | 180,911 | 30,045 | 16.61 |
| 2010 | 200,747 | 29,997 | 14.94 |
| 2011 | 215,770 | 49,893 | 23.12 |
| 2012 | 197,103 | 29,996 | 15.22 |
| 2013 | 136,563 | 40,507 | 29.66 |
| 2014 | 254,881 | 30,278 | 11.88 |
| 2015 | 277,448 | 34,457 | 12.42 |
| 2016 | 37,000 | 37,000 | 100.00 |
| 2017 | 244,499 | 34,826 | 14.24 |
| 2018 | 74,000 | 30,131 | 40.72 |
| 2019 | 806,000 | 41,143 | 5.10 |
| Average | 238,629 | 35,298 | $26 \%$ |

All regional PIT tag detection data including release and detection history are available in the PTAGIS database maintained by the Pacific States Marine Fisheries Commission. We queried

PTAGIS (https://www.ptagis.org/) in April 2020 to retrieve available PIT-tag detection information for all Summer Chinook juveniles released in the Yakima Basin from 2010 through 2019 (Table 2). For each fish with a PIT-tag code, we constructed a detection history, or record indicating all detection locations and whether the tagged fish was detected or not detected at each juvenile detection site, focusing on Prosser, McNary, John Day and Bonneville dams (PRO, MCJ, JDJ, B2J, BCC), and by the Estuary Towed Experimental Array (TWX).

Figure 2. Number of released subyearling Summer Chinook with and without PITtags from 2009 through 2019 at different acclimation sites (Marion Drain Hatchery, Nelson Springs, Prosser Hatchery, Roza Dam, Stiles Pond and Wapatox Diversion) color-coded by broodstock (WENN, WELL/ENT and WELL). The blue, red and gray boxes represent the "Wenatchee Hatchery Stock (WENN)", "either Wells Hatchery (WELL) stock or from Eastbank Hatchery (ENT) [WELL/ENT]", and "Wells Hatchery Stock (WELL)", respectively. The value in each plot is the number of fish that was released with (green colour) or without PIT-tags (red colour).

Table 2. The number of PIT-tagged subyearling Summer Chinook released at the different locations and dates (Early, Mid and Late) from release years 2009 through 2019. Note: Fish have usually been released during April, May and June every year. Releases on or before May 10, May 11 through May 25; and after May 25 are represented as Early, Mid and Late release periods, respectively.

### 2.3. Statistical analyses

### 2.3.1. Survival and Detection Probability

The juvenile survival probability (Juvenile to Prosser and McNary) was estimated for each release (four locations and three release dates), for each release year from 2009 through 2019. We estimated the average annual survival rate by pooling the data for each year. For releases from 2009 through 2018 a logistic regression model Neeley 2012) was used to estimate survival. Beginning in 2019 and in this report, survival probability from release locations to downstream detection at McNary Dam and the detection rate of PIT-tagged Summer Chinook smolts at Prosser and McNary dams were estimated using the Cormack-Jolly-Seber (CJS) mark-recapture model (see, White and Burnham 1999; Lebreton et al. 1992; Williams, et al. 2002, Conner et al. 2015), which has been commonly used within the Federal Columbia River Power System (FCRPS) to estimate survival rates for juvenile salmon and steelhead (Tuomikoski et al. 2013). The model uses multiple detections of individually marked fish at several dams with PIT-tag detection capabilities (i.e. antenna arrays). One of the assumptions of the CJS model is that there is no immigration or emigration during capture and recapture intervals, which is valid for discrete tag groups migrating through the hydrosystem (which involves passage at several hydroelectric dams) because fish behavior is relatively consistent
(all fish are moving in one direction and over a relatively short period; see Conner et al. 2015). All of the assumptions of the CJS models are considered to be met.

Similarly, to determine how release period (April, May and June) and fish size affect the survival rate from the release location to Prosser, and Prosser to McNary, we introduced fish size and release period as covariates in the CJS model. This CJS model was built within RMark (Laake 2019) in R, an extension of Program MARK (White and Burnham 1999). The detailed methodology is found in another study that is about Spring Chinook Salmon smolt released at Roza Dam (Appendix C).

### 2.3.2. Relationship between annual survival rate and river flow

Several environmental factors are known to influence downstream smolt survival, and river flow is among the most impactful (Raymond 1968; Connor et al. 2003; Tiffan et al. 2009). We therefore further evaluated whether there was a relationship between the annual survival rate and the average river flow for two summer months (May and June) measured below Prosser Dam. We chose only May and June because most of the juvenile Summer Chinook were released from the end of April $\left(29^{\text {th }}\right)$ to the first week of June $\left.\left(5^{\text {th }}\right)\right)$ from 2009 through 2019 (See Figure 2), and they usually start to migrate downstream from 2 or 3 days after release, leaving the Yakima River within 3 or 4 weeks after release. Given this timing, May and June's flow can be the most influential factor for the outmigration of this species. For the river flow data, we downloaded river flow data for the Bureau of Reclamation gaging station (YRPW) located below Prosser Dam in the Yakima River, using the Hydromet site: https://www.usbr.gov/pn/hydromet/yakima/yakwebarcread.html, which was accessed in April 2020.

### 2.3.3. Relationship between survival rate, release month and fish size

Among the available PIT-tagged fish, only a few had fish length information, so we selected only those tag groups with fish length information for the analysis. Fish release dates were categorized by month. As mentioned under subheading 2.3.1, we used fish length and release month as covariates in the CJS model. Using this model, the average survival rates from release location to Prosser Dam, and from Prosser to McNary Dam were estimated for release groups with different release months (April. May, June) and different average fish lengths.

### 2.3.4. Travel time and rate of migration or rate of travel

Travel time was estimated as the difference between the date of release or the date of detection at Prosser Dam and the date of detection at Bonneville Dam. For fish released below Prosser, we estimated travel time as the difference between the release date and the date of detection at Bonneville Dam. For fish released above Prosser Dam (PRO), travel time from Prrosser to Bonneville was estimated as the difference between the date of detection at Prosser Dam and the detection date at Bonneville Dam. We estimated travel time for each of three release months (April, May and June). Migration rate or rate of travel was calculated as length of the reach of interest (km) divided by travel time.

### 3.0. Results and discussion

### 3.1. Fish length

A total of 327,834 PIT-tagged juvenile Summer Chinook were released from 2010 through 2019, but some information such as fish size at tagging was not available in the downloaded PIT tag data. Only 42,868 had the fish size information, which was about $13 \%$ of the total PIT tagged fish released during this period. Based on the available data, the average size of the fish (fork length) at the time of tagging was 67.78 mm (See Figure 3). However, the size of the fish of the groups released in different months (March, April and May) was found to be different. Our expectation was that fish released later would be bigger than the fish released earlier, but we found that fish released in May were bigger than the fish released in June. The average fork lengths of the groups released in April, May and June were $66.98 \pm 0.115 \mathrm{~mm}, 74.17 \pm 0.06 \mathrm{~mm}$, and $61.88 \pm 0.105 \mathrm{~mm}$ at the time of tagging, respectively. Not getting the same result as we expected might be due to a number of reasons. One possible reason is that the sample sizes $(\mathrm{N})$ were different among the groups released in different months. There was a very large number of lengths in the May release group $(38,874)$, whereas the June release group had only 1844 measured fish (Figure 3). It is likely the smaller sample size did not represent the actual range of sizes of the fish released in June. Another reason could be the effect of temperature. The fish released later (June) might have been brought from the hatchery, which was located in other area of the Yakima basin. The fish reared at Prosser Hatchery grow faster than the fish reared in other hatcheries in the Yakima Basin because the surface water and groundwater used to rear fish are warmer.

Figure 3. Frequency (count) by fish length (fork length, mm) at the time of tagging for all releases made in April, May and June.

### 3.2. Detection Probabilities at McNary and Prosser

The rate of detection of juvenile Summer Chinook at McNary Dam varied among years (Table 3). The highest detection rate of this run was in $2013(23.89 \pm 1.20 \%)$, whereas the lowest detection rate was in 2015 ( $6.88 \pm 4.70 \%) .2015$ was a drought year and less water in the Yakima basin. In general, the detection rate depends upon the proportion of fish that pass dams via juvenile bypass systems where detectors are installed. In recent years, increasing spill and the use of surface-passage structures (RSWs, TSWs) at dams are a primary management strategy to increase survival of juvenile fish passing dams within the Federal Columbia River Power System. Greater use of spillways results in a lower proportion of fish entering juvenile bypass systems where PIT tags can be detected (Widener et al. 2018), and fluctuations in spill and flow can produce variable detection rates among years or within a migration season.

Table 3. Annual detection rate (in percent) at McNary Dam (and its Standard Error, SE); and the detection history (number of fish detected/not detected at McNary and Bonneville Dams) during outmigration of the released Summer Chinook during the period from 2010 through 2019. Enumeration of fish fate (release/detection histories) is coded by detection (1) and no detection (0). The code "1.0.0." means no juvenile detection after release, "1.0.1" means not detected at McNary Dam but detected at Bonneville Dam, "1.1.0" means detected at McNary Dam but not at Bonneville Dam, and "1.1.1" - detected at both Dams (McNary and Bonneville Dams).
Note: The number of detections attributed to Bonneville Dam (BON) includes fish that were detected either at John Day Dam (JDJ), Bonnevile Dam (B2J or BCC), or by the Estuary Towed Array (TWX).

| Year | Release/detection history (Number of PITtagged fish) |  |  |  | Detection <br> Probability \% (p) |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 1.0.0. | 1.0.1. | 1.1.0. | 1.1.1. | p | SE |
| 2010 | 28021 | 700 | 865 | 161 | 18.70 | 1.32 |
| 2011 | 44591 | 2251 | 2151 | 328 | 12.50 | 0.60 |
| 2012 | 27335 | 1469 | 830 | 187 | 11.29 | 0.70 |
| 2013 | 27618 | 920 | 1360 | 288 | 23.89 | 1.20 |
| 2014 | 29796 | 300 | 361 | 67 | 18.25 | 2.00 |
| 2015 | 33785 | 27 | 15 | 2 | 6.88 | 4.70 |
| 2016 | 32451 | 932 | 1933 | 230 | 19.79 | 1.16 |
| 2017 | 16545 | 604 | 308 | 77 | 11.30 | 1.21 |
| 2018 | 29867 | 123 | 11 | 27 | 18.00 | 3.14 |
| 2019 | 40592 | 334 | 199 | 26 | 7.22 | 1.36 |

In 2019, a total 41,071 juvenile Summer Chinook with PIT tags were released from the 4 locations (Buckskin Slough, Roza juvenile bypass, Wapatox juvenile bypass and below Prosser Dam). The average rate of detection at McNary Dam for the 2019 release was found to be $7.22 \%( \pm 1.36 \% \mathrm{SE})$, see table 4), whereas the detection at Prosser was about $43.75 \pm 6.23 \%$. The highest detection rate for a release group at McNary Dam was for Prosser releases $(7.22 \pm 1.36 \%$, see Table 4$)$. However, there were no detections at McNary Dam for the group released into the juvenile bypass at Wapatox Dam on the Naches River (Table 4). The group released below Prosser would be expected to have low mortality compared to the groups released into other areas, which are relatively far from the McNary Dam compared to the Prosser site. In general, travel distance is considered to be an important factor influencing survival rate. As travel distance increases, mortality also increases.

For all upstream release groups combined, the average (pooled) detection rate at Prosser for 2019 groups was about $43.75 \pm 6.23 \%$; whereas the average detection rate at McNary was only $7.22 \pm 1.36 \%$.

Among the release groups, the highest detection rate at Prosser was $57.4 \pm 6.1 \%$ for the group released below Roza Dam, whereas the detection rate of this group at McNary Dam was about $5.94 \pm 2.4 \%$ (Table 4).The fish released at Wapatox had only 129 detections at Prosser, and there were no detections of this group at or below McNary Dam (Table 4).

Table 4. Release/detection history and detection rate at Prosser (PRO) and McNary Dam (McN) for the groups of Summer Chinook released in 2019.

## 4A. Detection rate at Prosser Dam (PRO)

| Release/detection history | Number of fish (juvenile or smolts) |  |  |
| :--- | :---: | :---: | :---: |
|  | Buckskin | Roza | Prosser |
| Wapatox |  |  |  |
| 1. No juvenile detection after release (1.0.0) | 9321 | 8186 | 10137 |
| 2. Not detected at PRO but detected at <br> McN $(1.0 .1)$ | 7 | 33 | 0 |
| 3. Detected at PRO but not detected at <br> McN $(1.1 .0)$ | 1031 | 2001 | 129 |
| 4. Detected at both Dams (111) | 6 | 34 | 0 |
| Detection rate at PRO $\%( \pm \mathrm{SE})$ | $46.1 \pm 9.1$ | $57.4 \pm 6.1$ | NA |

## 4B. Detection rate at McNary Dam (McN)

| Release/detection history | Number of fish (juvenile or smolts) |  |  |  |
| :--- | :---: | :---: | :---: | :---: |
|  | Buckskin | Roza | Prosser | Wapatox |
| 1. No juvenile detection after release (1.0.0) | 10335 | 10092 | 9899 | 10137 |
| 2. Not detected at McN but detected at <br> BON (1.0.1) | 17 | 95 | 222 | 0 |
| 3. Detected at McN but not detected at <br> BON (1.1.0) | 12 | 61 | 126 | 0 |
| 4. Detected at both Dams (111) | 1 | 6 | 19 | 0 |
| Detection rate at McN \% ( $\pm$ SE) | $5.5 \pm 5.4$ | $5.94 \pm 2.4$ | $7.9 \pm 1.7$ | NA |

Note: Some of the juveniles were detected at John Day Dam but not detected at BON. The number of detections attributed to Bonneville Dam (BON) includes fish that were detected either at John Day Dam (JDJ), Bonnevile Dam(B2J or BCC), or by the Estuary Towed Experimental Array (TWX).

### 3.3. Juvenile Release-McNary Survival rate

### 3.3.1. Annual juvenile Release-McNary Survival rate and its temporal trend

Among the years from 2010 through 2019, the survival rate of juvenile Summer Chinook from release to McNary Dam varied among years (Figure 4; Table 5). The highest average annual survival rate was in $2011(40.15 \pm 1.94 \%)$ and the lowest was in 2015 ( $0.73 \pm 0.47 \%)$. The average annual
survival rate from all release locations to McNary Dam for 2019 was $7.22 \pm 1.35 \%$, which was higher than 2018's survival rate ( $2.58 \pm 0.41 \%$ ).

Figure 4. Average annual survival rate (release to McNary Dam) of juvenile Summer Chinook released from 2010 through 2019.

It is important to understand why the survival rate varied among years. It was high in 2011 but low in 2015. The juvenile survival might have been affected by many factors such as different brood stocks, release timing or river flow and including other variables. On average the survival rate in 2011 was very high (Table 5 and Figure 4). Looking at individual groups in 2011, the highest survival rate was for the group released into Buckskin Slough on the lower Naches River, which was released before May $10^{\text {th }}$, and its brood stock was Wenatchee (Eastbank hatchery, see Figure 2). For Stiles Pond, also on the lower Naches, in 2011, the survival rate was also high even though these fish were released in the middle period (May 11 through May $25^{\text {th }}$ ). The brood stock for Stiles was from Priest Rapids Hatchery.

Despite different brood stocks, release times and release locations, both groups (Stiles and Buckskin) had relatively high survival rates in 2011 compared to other years. These results suggest that other external factors might have played a role in increasing the survival rate. We further explored whether the river flow at Prosser has an effect on survival rate. We built the univariate relationship between the average river flow for May and June and the annual survival rate, and found that survival rate was strongly influenced by the May and June average river flow $\left(\mathrm{R}^{2}=0.45, \mathrm{p}=0.03\right.$, see Figure 5). It
indicates that survival rate was a function of river flow, but even though this relationship was statistically significant, it explained only about $45 \%$ of the annual variation in survival rate. Temperature or predation or interactions effect between temperature and flow or other factors might also have affected the survival rate. Further investigations, especially into how release period and fish size survival rate, are discussed in a later section (See 3.3.4. Effect of release period and fish size on survival).

Table 5. Total released smolt population, survival rate from release locations to McNary Dam and its Standard Error (SE) and the average river flow for May and June of each year from 2010 through 2019.

| Outmigration <br> /Released Year | Released Juvenile <br> (smolts) | Survival Rate (\%) |  | Average River flow <br> $(\mathrm{cfs})$ |
| :---: | :---: | :---: | :---: | :---: |
|  |  | 18.44 | 1.22 |  |
| 2011 | 49321 | 40.15 | 1.94 | 8476 |
| 2012 | 29821 | 30.20 | 1.89 | 7791 |
| 2013 | 30186 | 22.89 | 1.09 | 4475 |
| 2014 | 30524 | 7.68 | 0.79 | 4303 |
| 2015 | 33829 | 0.73 | 0.47 | 1074 |
| 2016 | 35546 | 30.74 | 1.73 | 6612 |
| 2017 | 17534 | 19.41 | 1.88 | 8177 |
| 2018 | 30028 | 2.58 | 0.41 | 5915 |
| 2019 | 41071 | 7.22 | 1.35 | 3482 |

Figure 5. Relationship between river flow (average of May and June) and the annual survival rate of juvenile Summer Chinook from release to McNary Dam for the years 2010 through 2019. The point with bar is the average survival rate and its $95 \%$ confidence interval (CI) for each year. The dotted line with the shaded area is the predicted linear trend (survival rate vs. river flow) and its $95 \% \mathrm{CI}$.

### 3.3.2. Survival rate among release locations and release periods

As mentioned above, the average annual survival rate (from release site to McNary Dam ) varied by year. The survival rate also varied by release location (Table 6 and Figure 6). In the experimental design, fish were not released at one or two location between Early, Mid and Late for a couple of years, it was therefore statistical comparisons among release-period comparisons were problematic to evaluate whether the survival rate had an effect of the release locations or release time or year effect. However, when the data were pooled by release period (Early, Mid and Late), the groups released earlier had about $19.39 \pm 10.75$ \% survival rate, whereas the mid and late releases had survival rates of $16.27 \pm 3.23 \%$ and $7.6 \pm 4.48 \%$, respectively. When releases were pooled by location, the highest survival rate was for the group released from Stiles Pond (20.3 $\pm 11.03 \%$ ) and the second highest survival rate was for the Buckskin Slough group ( $19.2 \pm 6.81 \%$ ). The lowest survival rate was for the group that was released from the Wapatox bypass ( $0.15 \pm 0.14 \%$, see Figure 7 ). Low survival for the release was must likely due to the low flow in the bypass because the bypass was designed for
a much higher flow. To overcome the problem, we built a release pipe form the mobile units to the top of the entrance of the exit pipe in the bypass to the river to release the fish. We had an expectation that the pipe would drop fish directly into the water above the entrance of the exit pipe. However still the survival rate was low. We had planned to release two raceways via this new pipe and transport two raceways directly across the road into the river for comparison. However, this year (2020) was not possible to test the strategy due to the current circumstance (COVID), we had to release all fish directly into the river with no tags, but will test the release strategy next year to understand why the survival rate for this release is low.

Table 6. Survival rate (\%) of the Summer Chinook from release site -to-McNary Dam from 2009 through 2019 released year (outmigration year) for the different releases (Stiles, Bucksin, Marin drain, below Roza bypass, Below Prosser Dam, Lower Yakima and Wapaptox). The survival rate and its standard Error (SE) are given for the 2019 estimates. Early, Mid and Late indicate released through 10th May; After 10th May Through May 25th; and After 25th; respectively.

|  | Stiles |  | Buckskin |  |  | Marion drain | Roza |  |  | Prosser |  | Yakima River Mouth | Wap atox |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Year | Mid | Late | Early | Mid | Late | Mid | Early | Mid | Late | Early | Mid | Early | Mid |
| 2009 |  | 1.5 |  |  |  |  |  |  |  |  |  |  |  |
| 2010 | 19.7 |  |  |  |  |  |  |  |  |  |  |  |  |
| 2011 | 39.7 |  | 43.7 |  |  |  |  |  |  |  |  |  |  |
| -2012. |  |  |  | 37.2 |  | 35.8 |  |  |  |  | 20.8 |  |  |
| 2013 |  |  |  | 29.8 |  |  |  |  | 20.9 |  |  |  |  |
| 2014 |  |  |  |  | 3.2 |  |  |  | 4.8 |  |  |  |  |

| 2016 |  |  |  |  |  |  |  |  |  |  |  | 31.2 |  |
| 2017 |  |  |  |  |  |  |  | 19.4 |  |  | 19.6 |  |  |
| 2018 |  |  |  |  |  |  |  | 4.9 |  |  |  |  | 0.3 |
| 2019 |  |  |  | $\begin{array}{r} 2.3 \\ \pm 2.1 \end{array}$ |  |  |  | $\begin{array}{r} 11.0 \\ \pm 4.2 \end{array}$ |  |  | $\begin{array}{r} 17.9 \\ +3.7 \end{array}$ |  | 00 |

Note: the survival rate estimates from 2009 through 2018 were taken from the previous report (Neeley 2019, Appendix G).

Figure 6. Juvenile survival rate from release site to McNary Dam for Summer Chinook groups released at different locations from 2009 through 2019.

Figure 7. Average survival rate of juvenile Summer Chinook to McNary Dam by release location from 2009 through 2019. Marion Drain and Yakima basin had only one estimate so that there was no variance.

### 3.3.3. Comparisons of survival rates from release to Prosser and from release to McNary

Survival rates from release to McNary in 2019 were much lower than survival from release to Prosser. For example, the survival rate for the group released from Buckskin Slough was about $21.4 \%$ to Prosser, but from Prosser to McNary it was only $10.5 \%$ for an overall survival rate from release to McNary of $2.3 \%$ (Table 7 and Figure 8), indicating that significant mortality can be observed in the lower Yakima river, probably because of higher water temperature and increased predation in the lower Yakima River, especially at the Yakima/Columbia river delta. From the delta, fish must travel 69 river kilometers ( rkm ) down the Columbia River to detection facilities at McNary Dam in addition to the 76 rkm from Prosser Dam to the delta, but on the basis of Columbia River smolt survival studies it is likely that most of the observed juvenile Summer Chinook mortality occurs in the Yakima River from Prosser to the delta.

Table 7. Juvenile Summer Chinook survival rate from each release site to Prosser Dam, from Prosser to McNary Dam, and from release site to McNary in 2019. "N" is the number of PIT-tags.

| Released Site | N | Release site to PRO |  | PRO to McN |  | Release site to McN |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Survival rate | SE | Survival rate | SE | Survival rate | SE |
| Buckskin | 10365 | 0.214 | 0.042 | 0.105 | 0.100 | 0.023 | 0.021 |
| Roza | 10254 | 0.387 | 0.029 | 0.284 | 0.110 | 0.110 | 0.042 |
| Prosser | 10266 |  |  | 0.179 | 0.037 | 0.179 | 0.037 |
| Wapatox | 10266 | 0.001 | 74.100* | 0.000 | 0.000 | 0.000 | 0.000 |

* Indicates the model convergence issue due to no downstream detections.

Figure 8. Juvenile Summer Chinook survival rate from each release site to Prosser Dam, from Prosser to McNary Dam, and from release site to McNary in 2019.

### 3.3.4. Effect of release period and fish size on survival

As mentioned in the methodology section, we built the CJS model with release period (month) and fish sizes as covariates using the fish size information available ( $\mathrm{N}=42,868$, see chapter 3.1, Fish size). Figure 9 (left side) shows that release period affected survival of small fish from release to Prosser Dam more than survival of large fish through the same reach. It shows if we release the fish with the size of 50 mm in April, the survival rate (the release site to Prosser Dam) would be above
$50 \%$, whereas if the same fish size released in June, its survival rate would be about only $10 \%$. However, for large fish, there seemed to have no effects on the survival rate.

From Prosser to McNary Dam (right side of Figure 9), the relationship of size to survival rate was similar for April and May releases, but release in June depressed the Prosser-to-McNary survival rate over the entire range of fish sizes. Standard errors for the groups released in April and May were found to be large, which might be due to small sample size. As mentioned in 3.1., the sample size was relatively low for the group release in April $(2,155)$ and June $(1,844)$ compared to May release $(38,874)$

Figure 9. Effect of release time and fish size on the rate of survival from the release site to Prosser, and from Prosser to McNary Dam. The shaded area is the standard Error (SE).

### 3.4. Travel time or rate of migration

The Summer Chinook releases generally exhibited immediate outmigration behavior after release, regardless of release date, but later outmigrants showed greater urgency. Travel days from Prosser Dam to Bonneville Dam for the groups released in April were about $73.08 \pm 37.77$ days, whereas the fish released in June took only $32.70 \pm 9.89$ days to reach Bonneville Dam.

Table 8. Travel days $\pm$ SE and rate of travel ( $\mathrm{km} /$ day $\pm$ SE) from Prosser to Bonneville Dam for the groups released in April, May and June from 2010 through 2019.

| Release <br> Month | Number of <br> PIT Tags | Travel days |  | Rate of migration <br> $(\mathrm{km} /$ day $)$ |
| :---: | :---: | :---: | :---: | :---: |
| April | 24,555 | $73.08 \pm 37.77$ |  | $7.19 \pm 0.10$ |
| May | 28,318 | $65.08 \pm 14.03$ |  | $8.15 \pm 0.04$ |
| June | 20,140 | $32.70 \pm 9.89$ |  | $16.64 \pm 0.03$ |

The distance between Prosser Dam and Bonneville Dam is normally given as 381 rkm and the rate of travel over that distance was $7.19 \mathrm{~km} /$ day for the group released in April; but the rate more than doubled ( $16.64 \mathrm{~km} /$ day) for the group released in June. The slower rate of travel for earlier releases indicates that fish released earlier spent more time in the mainstem in order to go through the series of physiological and morphological changes that allow for a transition to life in salt water. Before entering the ocean, anadromous species must change their osmoregulation process, undergoing physical adaptations of their gills and kidneys that build a tolerance to salt water. The study suggests that regardless when they were released, the Summer Chinook seemed to enter the ocean at nearly the same time, although outmigration survival rate was higher for the early release.

## 4. Acknowledgment

We thank all of the crews whose collective fish-tagging efforts over the years made this study possible. We are also grateful to David Lind who reviewed and provided valuable comments in the draft report. We would also like to thank Daylen Isaac who provided the hydrological data.

    2019 Annual Report, May 29, 2020

[^4]:    ${ }^{1}$ Mean of mean values for 1996-2014 post-eye to hypural plate lengths.

[^5]:    ${ }^{1}$ Including minor tributaries.

[^6]:    ${ }^{1}$ All marked fish observed in spawning ground carcass surveys in the Naches Basin are assumed to be CESRF fish.
    ${ }^{2}$ Water temperatures in the lower Yakima River were greater than $68^{\circ} \mathrm{F}$ for much of the late spring/summer migration since 2015 which likely caused many fish returning in recent years to seek cooler water in other parts of the Columbia Basin.

[^7]:    BIO = BioVita (BioOregon Protein Inc.) or control diet; EWS = EWOS (EWOS Canada Ltd.). All fish were switched to BioVita diet beginning May 3, 2007. All fish are progeny of wild/natural parents unless denoted as HH which designates the hatchery control line. "Avg BKD" denotes the average BKD ELISA ranking of the female parents whose progeny were in these ponds.
    ${ }^{2}$ The number of fish released is estimated as the total number of fish counted at marking less mortalities documented from mark to release.

[^8]:    ${ }^{1} \mathrm{BIO}=$ BioVita (BioOregon Protein Inc.) or control diet; STF = salt-water transition diet at acclimation sites. All fish are progeny of wild/natural parents unless denoted as HH which designates the hatchery control line beginning with brood year 2002. "Avg BKD" denotes the average BKD ELISA ranking of the female parents whose progeny were in these ponds.
    ${ }^{2}$ The number of fish released is estimated as the total number of fish counted at marking less mortalities documented from mark to release.

[^9]:    ${ }^{1}$ All fish are progeny of wild/natural parents unless denoted as HC which designates the hatchery control line beginning with brood year 2002. "Avg BKD" denotes the average BKD ELISA ranking of the female parents whose progeny were in these ponds. PRO=BioPro diet, VIT=BioVita diet, Bio-Oregon products.
    ${ }^{2}$ The number of fish released is estimated as the total number of fish counted at marking less mortalities documented from mark to release.

[^10]:    'All fish are progeny of wild/natural parents unless denoted as HC which designates the hatchery control line beginning with brood year 2002. "Avg BKD" denotes the average BKD ELISA ranking of the female parents whose progeny were in these ponds. PRO=BioPro diet, $\mathrm{VIT}=$ BioVita diet, Bio-Oregon products.
    ${ }^{2}$ The number of fish released is estimated as the total number of fish counted at marking less mortalities documented from mark to release.
    ${ }^{3}$ Due to problems at the acclimation site, Jack Creek raceways $5 \& 6$ were closed and all fish transferred and split between raceways 1-4 in February 2019.
