# YAKIMA/KLICKITAT FISHERIES PROJECT MONITORING AND EVALUATION <br> <br> Yakima Subbasin 

 <br> <br> Yakima Subbasin}

PROJECT NUMBER 1995-063-25
Report covers work performed under BPA contract \#00056662 REL 214
Report was completed under BPA contract \#00056662 REL 223

FINAL REPORT
For the Performance Period
May 1, 2020 through April 30, 2021
September 8, 2021

Joe Blodgett, Project Coordinator
Mark Johnston, Research Scientist/Project Lead Bill Bosch, Research and Data Coordinator/Editor

Yakima/Klickitat Fisheries Project
THE CONFEDERATED TRIBES AND BANDS OF
THE YAKAMA NATION
Toppenish, WA 98948

This report was funded by the Bonneville Power Administration (BPA), U.S. Department of Energy, as part of BPA's program to protect, mitigate, and enhance fish and wildlife affected by the development and operation of hydroelectric facilities on the Columbia River and its tributaries. The views in this report are the authors' and do not necessarily represent the views of BPA.

This report should be cited as follows:
Blodgett, J., M. Johnston, and B. Bosch (editors). 2021. Yakima-Klickitat Fisheries Project Monitoring and Evaluation - Yakima Subbasin, Final Report for the performance period May/2020-April/2021, Project number 1995-063-25, 388 electronic pages.

## Acknowledgements

Monitoring and evaluation efforts in the Yakima River Basin are the result of a cooperative effort by many individuals from a variety of agencies including the Yakama Nation Fisheries Program, the Washington Department of Fish and Wildlife, the United States Fish and Wildlife Service, the Columbia River Inter-Tribal Fish Commission, the National Oceanic and Atmospheric Administration Fisheries department as well as some consultants and contractors. We also wish to acknowledge and thank the Yakama Nation Tribal Council, U.S. Bureau of Reclamation, Yakima Subbasin Fish and Wildlife Recovery Board, Pacific States Marine Fisheries Commission, U.S. Forest Service Naches Ranger District, University of Idaho, Lars Mobrand and associates, University of Washington, and Central Washington University for their many contributions to this project including both recommendations and data services.

The core project team includes the following individuals: Joe Blodgett, Joe Hoptowit, Mark Johnston, Bill Bosch, Todd Newsome, Melinda Davis, Michael Porter, Sara Sohappy, Chris Frederiksen, Shubha Pandit, Andrew Matala, Daylen Isaac, Jim Matthews, and a number of technicians from the YN; Charles Strom and a number of assistants from the Cle Elum Supplementation and Research Facility; Michael Fiander and the crew at the Prosser Hatchery; Anthony Fritts, Gabe Temple, Christopher Johnson, and a number of assistants from the WDFW; We also receive considerable support from: Sharon Lutz, Susan Gutenberger and assistants from the USFWS; Don Larsen, Andy Dittman, Charlie Waters and assistants from NOAA Fisheries; Zach Penney, Doug Hatch, and many others at the Columbia River Inter-Tribal Fish Commission; and Kerry Naish and others at the University of Washington. The following individuals are now retired but we acknowledge their many and invaluable contributions over the years: Dave Fast, David Lind, Bill Fiander, and Paul Huffman of the YN, Curt Knudsen from Oncorh Consulting and Doug Neeley from IntSTATS Consulting.

Special acknowledgement and recognition is owed to all of the dedicated Yakama Nation and YKFP personnel working on various tasks including Ray Decoteau, Joe Yallup, Joe Jay Pinkham III (retired), Leroy Senator (retired), Sy Billy, Wayne Smartlowit, Morales Ganuelas, Pharamond Johnson, Steve Salinas, Shiela Decoteau, Jimmy Joe Olney, Conan Northwind, Quincy Wallahee, Andrew Lewis, Nate Pinkham, Gene Sutterlick, Germaine Hart, Jamie Bill, Nate Pinkham, William Manuel, Terrance Compo, Levi Piel, Winna Switzler, Florence Wallahee, Ted Martin and Arnold Barney. The accomplishments and achievements documented here are a direct result of their dedication and desire to seek positive results for the betterment of the resource. Also, these achievements are attainable because of the efficient and
essential administrative support received from all of the office and administrative support personnel for the YKFP including: Rubi Rodriguez, Joey Estrada, Shirley Alvarado, and Adrienne Wilson.

We would especially like to thank former contributors to the Yakima/Klickitat Fisheries Project including Bruce Watson, Joel Hubble, Steve Schroder, Todd Pearsons, Craig Busack, Ray Brunson, Joy Evered, and Bill Hopley. These individuals put in countless hours of hard work during the planning, design, and implementation of this project. Their contributions helped to lay a solid foundation for this project and our monitoring and evaluation efforts. Dan Barrett (retired) served as the manager of the CESRF from 1997-2002. He helped to lay a solid foundation for the critical work done day in and day out at the Cle Elum facility.

This work is funded by the Bonneville Power Administration (BPA) through the Northwest Power and Conservation Council's (NPCC) Fish and Wildlife Program. Michelle O'Malley is BPA's contracting officer and technical representative (COTR) for this project. David Byrnes and Patricia Smith served as COTRs in the past and contributed substantially to the project over the years.

## Executive Summary

The Yakima-Klickitat Fisheries Project (YKFP) is a joint project of the Yakama Nation (lead entity) and the Washington State Department of Fish and Wildlife (WDFW) and is sponsored in large part by the Bonneville Power Administration (BPA) with oversight and guidance from the Northwest Power and Conservation Council (NPCC). It is among the largest and most complex fisheries management projects in the Columbia Basin in terms of data collection and management, physical facilities, habitat enhancement and management, and experimental design and research on fisheries resources. The YKFP is attempting to evaluate all stocks historically present in the Yakima Subbasin and apply a combination of habitat restoration and hatchery supplementation or reintroduction, to restore the Yakima Subbasin ecosystem with sustainable and harvestable populations of salmon, steelhead and other at-risk species. This project and report address regional monitoring and evaluation strategies and sub-strategies as they apply to spring Chinook, summer/fall Chinook, and coho work in the Yakima Subbasin. This project (199506325) is related to numerous other projects in the Yakima Subbasin; additional information is available in the annual reports of these related projects.

The YKFP began a spring Chinook salmon hatchery program at the Cle Elum Supplementation and Research Facility (CESRF) near Cle Elum on the upper Yakima River in 1997. This program is a supplementation effort targeting the upper Yakima River population and is designed to test whether artificial propagation can be used to increase natural production and harvest opportunities while limiting ecological and genetic impacts. It is an integrated hatchery program because only natural-origin brood-stock is used and returning hatchery-origin adults are allowed to spawn in the wild. The program employs "best practice" hatchery management principles including reduced pond densities, strict disease management protocols, random brood-stock selection, and factorial mating to maximize effective population size. Fish are reared at the central facility, but released from three acclimation sites located near the central facility at: Easton approximately 25 km upstream of the central facility, Clark Flat about 25 km downstream of the central facility, and Jack Creek about 12 km upstream from the Teanaway River's confluence with the Yakima River. The CESRF collected its first spring Chinook brood-stock in 1997, released its first fish in 1999, and age-4 adults have been returning since 2001. The first generation of offspring of CESRF and wild fish spawning in the wild returned as adults in 2005. The program uses the adjacent, un-supplemented Naches River population as an environmental and wild control or reference system.

Adult returns of fall Chinook to the Yakima River Basin consist mostly of hatcheryorigin fish returning from releases averaging 1.6 million Upriver Brights annually from
the Prosser Hatchery which have occurred since 1983. Summer-run Chinook were extirpated from the Yakima Basin by 1970. To increase the temporal and spatial distribution of summer/fall run Chinook in the Yakima River Subbasin, the program began releases of Wells Hatchery summer-run Chinook in the Yakima River Basin in 2009. Coho were extirpated from the Yakima Subbasin by the early 1980s. Pursuant to U.S. v. Oregon court-mandated agreements, substantial numbers (annual average $>$ 700,000 ) of hatchery-reared coho salmon were released into the Yakima River since the mid-1980s. Prior to 1996 the primary purpose of releases was harvest augmentation and fish were released in sub-optimal spawning and rearing areas below Wapato Dam. With the inception of the YKFP in 1996, the objective of the coho program became "to determine the feasibility of reestablishing a naturally spawning coho population" and releases were moved upriver to more suitable habitats for natural coho.

Annual abundance of spring Chinook at Prosser Dam has increased from a 1982-2000 average of about 4,000 fish to a 2001-2020 average of about 9,500 fish. These increases can be attributed to returns from the Cle Elum supplementation program beginning in 2001, improved freshwater passage conditions, improved marine survival, and habitat restoration and enhancement work. Annual abundance of summer/fall Chinook at the Yakima River mouth has increased from a 1983-1999 average of about 1,200 fish to a 2000-2020 average of about 6,500 fish. While this increase coincides with improved ocean conditions, some of the increase may also be due to improved passage in the mainstem Columbia River, and improvements in spawning and rearing protocols. Approximately 250 summer-run Chinook were estimated to pass above Prosser Dam in 2020. The 2020/2021 adult passage over Prosser Dam was approximately 2,300 coho. An additional 970 adults returned directly into the Prosser Fish Hatchery. The hatchery is located approximately 1 mile below the dam and the returning adults are used for brood stock. Coho returns to Prosser averaged over 5,600 fish from 1998-2020 (an order of magnitude improvement from the average for years prior to the project) including estimated returns of wild/natural coho averaging over 800 fish annually since 2001.

Trends in adult productivity indices for Yakima Basin natural-origin spring Chinook appear to be very similar for both Upper Yakima and Naches populations. Trends in adult productivity indices for natural-origin coho are not as clear. Under present conditions, productivity for spring Chinook appears to peak at about 1,000 to 1,500 spawners and decline as spawner abundance approaches 2,000 fish or greater. These data indicate that density-dependent limiting factors depress natural productivity at fairly low population abundance in the Yakima River Basin. Until these factors are fully addressed, supplementation yields higher overall productivity rates and can be used to return adults to fisheries and to augment natural spawning populations.

For smolt migration years 2000 to present, annual abundance estimates of juvenile smolts migrating downstream at Prosser Dam averaged 209,900 wild/natural spring Chinook, 331,200 CESRF-origin spring Chinook, 44,000 wild/natural-origin coho, and 262,800 hatchery-origin coho. Preliminary smolt-to-adult survival indices averaged approximately $2.4 \%$ and $2.9 \%$ for natural-origin spring Chinook and coho, respectively. Because of many complexities associated with the production of smolt indices, these data are useful for analysis of trends but should not be used as direct citations of, or for comparisons of marked and unmarked, smolt-to-adult survival rates. Substantial juvenile mortality occurs as smolts migrate through the Yakima River system. Strategies have been proposed to address limiting factors and improve survival of emigrating Yakima Basin juveniles. As these strategies are implemented, we expect smolt and smolt-to-adult survival to improve.

Spatial distribution of spring Chinook spawners has increased as a result of acclimation site location, salmon homing fidelity and more fully seeding preferred spawning habitats. Spring Chinook redd counts in the Teanaway River increased from a pre-supplementation average of 3 redds per year to a post-supplementation average of 55 redds per year. Fall Chinook redd distribution in the Yakima River Basin appears to be experiencing a transition with an increasing proportion of redds observed above Prosser Dam in the most recent decade. This change is primarily attributed to substantial changes in lower Yakima River habitats in recent years. Redd counts and spatial distribution of coho have increased substantially in recent years, with over 200 redds enumerated annually on average in tributaries in the upper watersheds since 2004. In 2020/2021, 95 coho redds were observed in tributaries in the Naches and Upper Yakima Subbasins. Approximately 50 redds were found in the Naches River and over 70 were found in the mainstem Yakima River above Roza Dam.

Monitoring and evaluation of diversity metrics is primarily focused on the CESRF spring Chinook program in the Upper Yakima River. Generally, we have detected small, but significant differences between hatchery- and natural-origin fish in some juvenile and adult traits with many results already published in the peer-reviewed literature.

Overall average fine sediment levels in the Naches and Upper Yakima River subbasins over many years of sampling continue to trend downward.

We believe Yakima Basin spring Chinook contribute minimally to marine fisheries as their spatial and temporal ocean migration patterns do not appear to intersect with marine fisheries. However, Yakima Basin fall- and summer-run Chinook and coho do
contribute substantially to marine fisheries and to mainstem Columbia River fisheries from the mouth to the Hanford Reach area. Recreational spring Chinook fisheries have returned to the Yakima River Basin after a 40-year absence. This has contributed to improved relationships between all the Basin's stakeholders and increased opportunities for collaboration.

Supplementation has increased spring Chinook redd abundance in the Upper Yakima relative to the Naches control system. We observed an average increase in redd counts in the upper Yakima about $54 \%$ greater than that in the Naches system from the pre- to post-supplementation periods. Natural-origin returns of adult spring Chinook in the post-supplementation period (2005-2020) are trending downward relative to the pre-supplementation period (1982-2004) in both the Upper Yakima and Naches Rivers but the trend in the Naches control system is a steeper decline. After several generations of study, the results (many of which are published in the peerreviewed literature) from the spring chinook supplementation program in the Upper Yakima River demonstrate that a well-designed and carefully managed integrated hatchery program using $100 \%$ natural-origin broodstock can produce fish for harvest and return fish to the natural spawning grounds with minimal negative impacts to the target ecosystem. Coho re-introduction research in the published literature suggests that hatchery-origin coho, with a legacy of as many as 10 to 30 generations of hatchery-influence, can reestablish a naturalized population after as few as 3 to 5 generations of outplanting in the wild.

YKFP efforts to monitor and evaluate hatchery reform focus on the CESRF spring Chinook program which was designed explicitly for this purpose from its inception. By designing the program to use only natural-origin fish for brood-stock, the program has demonstrated reduced genetic divergence for the integrated program compared to a traditional segregated hatchery program. The CESRF is also meeting or exceeding scientific recommendations for proportionate natural influence (PNI) on an annual basis with a 20 -year mean annual PNI of $66 \%$. The project is thus far meeting or exceeding most other established objectives related to hatchery reform.

Major piscivorous predators in the Yakima River Basin include: common mergansers, American white pelicans, double-crested cormorants, gulls, great blue herons, northern pike minnows, and smallmouth bass. The project has initiated efforts to control the pike minnow and smallmouth bass populations.

Project results are communicated broadly through the annual science and management conference, technical reports and peer-reviewed journal publications (see references and project-related publications), and via several related web sites described in Appendix A.

## Introduction

The Yakima-Klickitat Fisheries Project (YKFP) is a joint project of the Yakama Nation (lead entity) and the Washington State Department of Fish and Wildlife (WDFW) and is sponsored in large part by the Bonneville Power Administration (BPA) with oversight and guidance from the Northwest Power and Conservation Council (NPCC). It is among the largest and most complex fisheries management projects in the Columbia Basin in terms of experimental design and research on fisheries resources, physical facilities, habitat enhancement and restoration, and data collection and management. Consistent with Wy-Kan-Ush-Mi Wah-Kish-Wit (CRITFC 1995) and using principles of adaptive management (BPA 1996; Salafsky et al. 2001), the YKFP is attempting to evaluate all stocks historically present in the Yakima Subbasin and apply a combination of habitat restoration and hatchery supplementation or reintroduction, to restore the Yakima Subbasin ecosystem with sustainable and harvestable populations of salmon, steelhead and other at-risk species.

The original impetus for the YKFP resulted from the landmark fishing disputes of the 1970s, the ensuing legal decisions in United States versus Washington and United States versus Oregon, and the region's realization that lost natural production needed to be mitigated in upriver areas where these losses primarily occurred. The YKFP was first identified in the NPCC's 1982 Fish and Wildlife Program (FWP) and supported in the U.S. v Oregon 1988 Columbia River Fish Management Plan (CRFMP). A draft Master Plan was presented to the NPCC in 1987 and the Preliminary Design Report was presented in 1990. In both circumstances, the NPCC instructed the Yakama Nation, WDFW and BPA to carry out planning functions that addressed uncertainties in regard to the adequacy of hatchery supplementation for meeting production objectives and limiting adverse ecological and genetic impacts. At the same time, the NPCC underscored the importance of using adaptive management principles to manage the direction of the Project. The 1994 FWP reiterated the importance of proceeding with the YKFP because of the added production and learning potential the project would provide. The YKFP is unique in having been designed to rigorously test the efficacy of hatchery supplementation. Given the current depressed status of many salmon and steelhead stocks, and the heavy reliance on artificial propagation as a recovery tool, YKFP monitoring results have great region-wide significance.

Supplementation is envisioned as a means to enhance and sustain the abundance of wild and naturally-spawning populations at levels exceeding the cumulative mortality burden imposed on those populations by habitat degradation and by natural cycles in environmental conditions. A supplementation hatchery is properly operated as an
adjunct to the natural production system in a watershed. By fully integrating the hatchery with a naturally-producing population, high survival rates for the component of the population in the hatchery can raise the average abundance of the total population (hatchery component plus naturally-producing component) to a level that compensates for the high mortalities imposed by human development activities and fully seeds the natural environment. However, it is important to recognize that "rebuilding natural populations will ultimately depend on improving habitat quality and quantity" (ISRP 2011, Venditti et al. 2017) of which habitat connectivity is an essential component (CRITFC 1995, Milbrink et al. 2011). Hatchery programs, even "state of the art" integrated supplementation programs designed to follow all of the best management practice recommendations (Cuenco et al. 1993, Mobrand et al. 2005), do not directly affect any of these habitat parameters which are vital to improving natural productivity. Therefore, the YKFP is working with partners in multiple forums to implement habitat restoration and water resource management projects designed to address factors limiting productivity (see Yakima Subbasin, Recovery, and Integrated plans).

The objectives of the YKFP are to: enhance existing stocks; re-introduce extirpated stocks; protect and restore habitat in the Yakima Subbasin; operate using a scientifically rigorous process that will foster application of the knowledge gained about hatchery supplementation and habitat restoration throughout the Columbia River Basin; and use Ecosystem Diagnosis and Treatment (EDT) and other modeling tools to facilitate planning for project activities. In strictly scientific terms the stated purpose of the project is, "to test the assumption that new artificial production can be used to increase harvest and natural production while maintaining the long-term genetic fitness of the fish population being supplemented and keeping adverse genetic and ecological interactions with non-target species or stocks within acceptable limits" (RASP 1992, BPA 1996). WDFW is addressing some critical uncertainties (see Columbia River Basin Research Plan and Critical Uncertainties for the Columbia River Basin Fish and Wildlife Program) related to genetic and ecological interactions under project 1995-064-25. We are working jointly with WDFW and CRITFC (2009-$009-00)$ to address fish propagation, predation, harvest, and monitoring and evaluation methodology uncertainties including:

Fish Propagation Question 1. Are current propagation efforts successfully meeting harvest and conservation objectives while managing risks to natural populations?
1.2. Can hatchery production programs meet adult production and harvest goals (integrated and segregated) while protecting naturally spawning populations?
1.4. What is the magnitude of any demographic benefit or detriment to the production of natural-origin juveniles and adults from natural spawning of hatchery-origin supplementation adults?
1.5. What are the range, magnitude and rates of change of natural spawning fitness of integrated (supplemented) populations, and how are these related to management rules including the proportion of hatchery fish permitted on the spawning grounds, and the proportion of natural origin adults in the hatchery broodstock?

Predation Question 1. Are the current efforts to address predation and reduce numbers of predators effective?

Predation Question 2. Are there actions other than removing predators that could reduce predation on listed species?

Harvest Question 1. Do current harvest and escapement strategies provide the expected results in supporting recovery efforts and providing harvest opportunities?

Monitoring and evaluation methods Question 1. Are current methods to ... count fish and to measure productivity adequate to cost effectively inform decisions?

Monitoring and evaluation methods Question 2. Are there innovative methods for counting fish and measuring their productivity that would better inform decisions?

YKFP-related project research in the Yakima River Basin has resulted in the publication of over 60 manuscripts in the peer-reviewed literature (see References and Project-Related Publications). The status of ongoing research relative to the above uncertainties is presented as part of this report.

This report includes sections on the following regional research, monitoring, and evaluation (RME) strategies: fish population status, harvest, hatchery, and predation. Each section addresses all relevant sub-strategies that apply to this project. The report addresses these strategies and sub-strategies as they apply to spring Chinook (Oncorbynchus tshanytscha), summer/fall Chinook (O. tshanytscha), and coho (O. kisutch) RM\&E work in the Yakima subbasin. Steelhead (O. mykiss) RME work is addressed in related VSP (2010-030-00), on-reservation watersheds (1996-035-01), and Kelt Reconditioning (CRITFC 2008-458-00 and 2007-401-00) projects. WDFW is addressing hatchery uncertainties related to genetic and ecological interactions under project 1995-064-25. YKFP-related habitat activities for the Yakima Subbasin are addressed under projects 1997-051-00 and 1996-035-01 (except for sediment sampling
which is addressed here). Hatchery Production Implementation (O\&M) is addressed under project 1997-013-25. Data and findings presented in this report should be considered preliminary until results are published in the peer-reviewed literature.

Study Area
The project study area is the Yakima River Basin WRIA 37/38/39 (Figure 1).

Figure 1. Yakima River Basin and Yakama Nation/YKFP-related artificial production and monitoring facilities (map provided by Paul Huffman).

## Fish Population Status Monitoring

## Status and Trend of Adult Fish Populations (Abundance)

Methods: Adult salmon populations in the Yakima River Basin are enumerated at Prosser Dam using video equipment installed in all three adult fish ladders (monitoringresources.org methods 143, 144, 307, 418, 515). At both Prosser and Roza Dams, adult fish traps are also used on a seasonal basis for biological sampling and enumeration (monitoringresources.org methods 135). When the Roza adult trap is not in operation, video equipment is also employed at the adult fish ladders there. However, camera placement and actual viewing area are limited; these combined with water clarity issues during certain river conditions all affect video enumeration at Roza Dam. Automatic Passive Integrated Transponder (PIT) tag detectors are also employed at all fish ladders at both dams (see sites RZF and PRO in ptagis.org). For the safety and protection of personnel and equipment, video and PIT-detection equipment are removed during periods of high river flow. In these instances, biologists attempt to extrapolate fish counts using data from before and after the high flow event. Although adult passage over spillways is believed to occur when flows are favorable, Prosser Dam counts are generally considered by Yakama Nation biologists to be within $+/-5 \%$ of actual fish passage. Roza Dam counts during trap operation (generally the entire spring Chinook counting period, March-September) are considered virtually $100 \%$ accurate; however, during the late fall and winter counting period when video equipment is used at least part of the time, accuracy may fall to only $50-75 \%$ of actual fish passage based on preliminary evaluation of PIT tag detection data. Fish are denoted as hatchery- or natural-origin based on presence or absence respectively, of observed external or internal marks or tags (monitoringresources.org method 342). Chinook are denoted as spring-, summer-, or fall-run based on review of PIT-detection data and visual observations of coloration and body morphometry.

At Prosser Dam, time-lapse video recorders (VHS) and a video camera were used at viewing windows at each of the three fishways. Digital video recorders (DVR) and progressive scan cameras (to replace the VHS systems) were tested at each of the three Prosser fishways in 2007 and became fully operational in February of 2008. The new system functions very similarly to the VHS system but provides digital video data readily downloadable to the viewing stations in Toppenish. This new system also allows technicians in Toppenish to scan rapidly to images of fish giving more timely and accurate fish counts. The technicians review the images and record various types of data for each fish that migrates upstream via the ladders. The data are entered into a Microsoft Access database. Similarly, adult trap sample data for operations at both

Prosser and Roza Dams are entered into Microsoft Access databases. Post-season, counts are reviewed and adjusted for data gaps and knowledge about adult and jack lengths from sampling activities with corrections made to our master data sets. Daily dam count (including trap and video counts) reports and Yakima Basin adult trap sampling (login required) data for the Prosser and Roza data sets are available at: https://vakamafish-nsn.gov/fish-data.

Spring Chinook began returning from the Cle Elum Supplementation and Research Facility (CESRF) in 2000 (jacks) and 2001 (adults). All CESRF-origin spring Chinook are marked. Due to physical and logistical constraints at the Prosser Hatchery it is not possible to mark all hatchery releases of summer/fall run Chinook without jeopardizing fish health and survival but these issues are being addressed through the Master Planning process (Yakama Nation 2019). Thus, enumeration of hatchery- and natural-origin summer/fall run Chinook adult returns is not presently available but will be available in the future. New marking protocols made it possible to distinguish hatchery- and natural-origin coho beginning with return year 2001.

## Results:

Figure 2. Estimated counts of natural- and Cle Elum Supplementation and Research Facility (CESRF-) origin spring Chinook (adults and jacks) at Prosser Dam, 1982-present.

Figure 3. Estimated returns of adult and jack summer- and fall-run Chinook to the Yakima River mouth, 1983-present.

Figure 4. Estimated counts of marked (presumed hatchery-origin) and unmarked (presumed natural-origin) Coho (adults and jacks) at Prosser Dam 1986-present.

Figure 5. Estimated counts of natural- and Cle Elum Supplementation and Research Facility (CESRF-) origin spring Chinook (adults and jacks) at Roza Dam, 1982-present.

Figure 6. Average daily passage of Chinook and Coho (adults and jacks) at Prosser Dam, 2011-2020.

Figure 7. Passage timing of adult and jack Chinook at Prosser Dam in 2020 by run (see Methods).

## Discussion:

Annual abundance of spring Chinook at Prosser Dam has increased from a 1982-2000 average of about 4,000 fish to a 2001-2020 average of about 9,500 fish (Figure 2). Annual abundance of spring Chinook at Roza Dam has increased from a 1982-2000 average of about 2,300 fish to a 2001-2020 average of approximately 6,400 fish (Figure 5). These increases beginning in 2001 coincide with the first adult returns from the Cle Elum supplementation program. However, freshwater passage conditions, marine survival, and habitat restoration and enhancement work also affect survival and return rates. The lower adult returns observed in 2003 and 2007 coincide with notable droughts during the corresponding smolt outmigration years of 2001 and 2005. Returns in several recent years (beginning in 2015) were affected by thermal barriers in the lower Yakima River during the adult migration timeframe. Discussion of uncertainties relating to the Cle Elum spring Chinook supplementation program is included under Hatchery Monitoring later in this report. Additional data and detail on the Cle Elum spring Chinook supplementation program and the status of natural- and CESRF-origin spring Chinook in the Yakima River Basin are provided in Appendix B.

Although some natural production is occurring, adult returns of fall Chinook to the Yakima River Basin consist mostly of hatchery-origin fish returning from annual releases of Upriver Brights from the Prosser Hatchery which have occurred since 1983 and averaged about 1.9 million since 1999 (Yakama Nation 2019). In addition, the Yakama Nation has a goal of re-establishing Summer-run Chinook which were
extirpated from the Yakima Basin by 1970. Pursuant to this goal we began releases of Wells Hatchery summer-run Chinook in the Yakima River Basin in 2009. Annual abundance of summer/fall Chinook at the Yakima River mouth has increased from a 1983-1999 average of about 1,200 fish to a 2000-2020 average of about 6,500 fish (Figure 3). While this increase coincides with improved ocean conditions, some of the increase may also be due to improved passage in the mainstem Columbia River, and improvements in spawning and rearing protocols. By re-establishing the summerrun component we seek to increase the temporal (Figures 6 and 7) and spatial distribution of summer/fall run Chinook in the Yakima River Subbasin (Yakama Nation 2019). Approximately 250 summer-run Chinook were estimated to pass above Prosser Dam in 2020 (Figure 7).

Coho were extirpated from the Yakima Subbasin by the early 1980s. Pursuant to U.S. v. Oregon court-mandated agreements, substantial numbers (annual average $>700,000$ ) of hatchery-reared coho salmon were released into the Yakima River since the mid1980s. Prior to 1996 the primary purpose of releases was harvest augmentation and fish were released in sub-optimal spawning and rearing areas below Wapato Dam. With the inception of the YKFP in 1996, the objective of the coho program became "to determine the feasibility of reestablishing a naturally spawning coho population" and releases were moved upriver to more suitable habitats for natural coho. Monitoring of these efforts to re-introduce a sustainable, naturally spawning coho population in the Yakima Basin have indicated that coho returns averaged 5,600 fish from 1998-2020 (an order of magnitude improvement from the average for years prior to the project) including estimated returns of wild/natural coho averaging over 800 fish annually since 2001 (Figure 4).

## Status and Trend of Adult Productivity

## Methods:

We used recruit-per-spawner relationships (Ricker 1975) to describe adult-to-adult productivity indices. Species-specific methods were as follows.

## Spring Cbinook

Estimated natural-origin spawners for the Upper Yakima River were calculated as the estimated escapement above Roza Dam plus the estimated number of spawners between the confluence with the Naches River and Roza Dam. Total natural-origin returns to the Upper Yakima River were developed using run reconstruction techniques (Appendix B). Age composition for Upper Yakima returns was estimated from spawning ground carcass scale samples (monitoring resources.org method 112) for the years 1982-1996 and from Roza Dam brood-stock collection samples (Knudsen et al. 2006; Appendix B) for the years 1997 to present. Since age-3 fish
(jacks) are not collected for brood-stock in proportion to the jack run size, the proportion of age-3 fish in the upper Yakima for 1997 to present was estimated using the proportion of jacks (based on visual observation) counted at Roza Dam relative to the total run size.

Estimated spawners and total returns for Naches River Subbasin natural-origin spring Chinook were calculated using run reconstruction techniques (Appendix B). Age composition for Naches Basin age-4 and age- 5 returns were estimated from spawning ground carcass scale samples (monitoring resources.org method 112). The proportion of age-3 fish was estimated after reviewing jack count (based on visual observations) data at Prosser and Roza dams.

Estimated spawners at the CESRF were the total number of wild/natural fish collected at Roza Dam and taken to the CESRF for production brood-stock (Knudsen et al. 2006; Appendix B). Total returns of CESRF-origin fish were based on run reconstruction and Roza dam sampling operations. Age composition for CESRF fish was estimated using scales and PIT tag detections from CESRF fish sampled passing upstream through the Roza Dam adult monitoring facility (Knudsen et al. 2006; Appendix B).

## Cobo

From central British Columbia south, the vast majority of coho salmon adults are 3-year-olds, having spent approximately 18 months in fresh water and 18 months in salt water (Loeffel and Wendler 1968, Wright 1970). Therefore, we estimated a naturalorigin productivity (recruits per spawner) index by dividing natural-origin returns to Prosser Dam by the estimated returns to Prosser Dam three years prior. We computed this index for both adult and combined adult and jack returns per adult and combined adult and jack spawner. Note that this method will bias productivity estimates high, as it assumes no natural production from hatchery-origin spawners.

## Summer/Fall Run Cbinook.

Adult fall Chinook returning to the Yakima Basin consist of hatchery-origin returns from releases at and above Prosser Dam and natural-origin returns from fish spawning naturally in the Yakima River. Due to fiscal, physical, logistical, and policy considerations, only a small proportion of hatchery-origin releases have been externally marked. Therefore, it is impossible at present to know the origin of unmarked adult fall Chinook counted at Prosser. Additional marking is proposed for hatchery-origin releases as part of the Master Plan (Yakama Nation 2019), which will allow development of a comprehensive brood/cohort age at return table for naturaland hatchery-origin returns. Methods and results for evaluating adult productivity of summer/fall run Chinook will be included in future reports and publications as the data become available.

## Results:

Figure 10. Productivity indices for age-3 natural-origin coho, brood years 2001-2017.

## Discussion:

Recruit per spawner data for the Upper Yakima and Naches spring Chinook populations are highly correlated (Tables 1 and 2; Pearson's correlation
coefficient $=0.87$ ) and analysis of variance indicates the means ( $\pm$ one standard error) in the 32-year data set are not different (Upper Yakima=1.47 $\pm 0.39$; Naches $=1.57 \pm 0.31 ; P=0.85$ ). Trends in adult productivity indices for Yakima Basin natural-origin spring Chinook are also very similar for both Upper Yakima (Figure 8) and Naches (Figure 9) populations. Under present conditions, productivity for spring Chinook appears to peak at about 1,000 to 1,500 spawners and declines as spawner abundance approaches 2,000 fish or greater (Figures 8-9). The trend in adult productivity indices for natural-origin coho (Figure 10) is not as obvious, and 2014 marked the first year that we observed high coho spawner escapements (when hatchery-origin spawning escapement is included) similar to those we have observed with spring Chinook in some recent years. These data indicate that density-dependent limiting factors (see YSFWPB 2004) depress natural productivity at fairly low population abundance in the Yakima River Basin, as is the case for most salmon populations throughout the Columbia River Basin (ISAB 2015). Until these factors are fully addressed, supplementation yields higher overall productivity rates and can be used to return adults to fisheries and to augment natural spawning populations (Table 3). While higher spawner abundances under present conditions do not yield increased adult production, these fish still contribute to more fully seeding available habitats, increased spatial and temporal diversity, and nutrient enhancement that should eventually lead to increased natural food supply and higher productivity in the future (NRC 1996, see especially pp. 368-369; Kiffney et al. 2014).

## Status and Trend of Juvenile Abundance

Methods: The Yakama Nation releases a number of hatchery-origin smolts annually pursuant to U.S. $v$ Oregon Management Agreements. Adult returns from these releases serve to mitigate for lost harvest opportunity (due to alteration of the Columbia River ecosystem and associated losses in natural production and productivity), to augment the number of fish spawning naturally (supplementation), or a combination of the two. Juveniles are released from many locations as yearlings or subyearlings depending on the goals of the specific programs. As these juveniles migrate downstream, they are mixed with naturally produced juveniles.

Above Prosser Dam, a portion of the river flow is diverted into the Chandler canal to generate electrical power and serve irrigation districts downstream. Juvenile fish are diverted into the Canal (and subsequently the Chandler juvenile monitoring facilityCJMF, Figure 1) at different rates depending on river and canal flow. Smolt sampling efforts at the CJMF near Prosser Dam were conducted annually from early winter through early summer corresponding with salmon smolt out-migrations. A portion of entrained salmon outmigrants (regulated by a timed gate) was manually counted and sampled for biological data on a daily basis and all PIT tagged fish were interrogated.

Sampling methods were described in Busack et al. (1997) and were consistent with monitoringresources.org methods 1562, 1563, 1595, and 1614.

Paired releases of PIT-tagged smolts were made in order to estimate the fish entrainment and canal survival rates in relation to river conditions and canal operations. For outmigration years 1999 through 2014, these data were used to generate a multi-variate river flow/canal entrainment relationship (D. Neeley 2010 and 2012a). Over a range of flow diversion rates, juvenile fish entrainment rates generally fit a logistic curve: at low diversion rates, the entrainment rate is lower than the diversion rate, and at high diversion rates the entrainment rate is higher than the diversion rate. In recent years it became difficult to adapt the model to higher winter and spring flows and to river channel changes, partly because at low diversion rates it was difficult to capture enough fish to get many point estimates of entrainment rate. The releases that were made, however, still tended to support a low entrainment rate relative to diversion rate at high river flows. For some years, Prosser smolt passage estimates produced by this model were outside of what were considered reasonable bounds (e.g., entrainment-based Prosser passage estimates approached or even exceeded known releases for hatchery-origin spring Chinook far upstream). This required us to reevaluate and change our methodology. The proportions of all PITtagged smolts released above Prosser and detected at mid-Columbia dams that were previously detected in the Chandler Canal bypass now serve as estimates of bypassdetection efficiency. Expanded Prosser passage estimates were then derived using the juvenile sample counts and detection efficiencies as described in Appendix C. These methods were generally consistent with monitoringresources.org methods 435, 623 and 1743.

## Results and Discussion:

At the CESRF, the number of release groups and total number of spring Chinook released diverged from the facility goal of 810,000 smolts in some years. In brood year 1997, the Jack Creek acclimation facility was not yet complete and project policy and technical teams purposely decided to under-collect brood stock to allow a methodical testing of the new facility's operations with less risk to live fish, which resulted in the stocking of only 10 of the 18 raceways. In brood year 1998, the project did not meet facility release goals due to a biological specification that no more than $50 \%$ of returning wild fish be taken for brood stock. As a result, only 16 raceways were stocked with progeny of the 1998 brood. In the same year, raceway 4 at the Jack Creek acclimation site suffered mechanical failures causing loss of flow and reduced oxygen levels and resulted in the loss of approximately one-half the fish in this raceway prior to release. In the drought year of 2001, a large number of returning adults presented with high enzyme-linked immunosorbent assay (ELISA) levels of Renibacterium salmoninarum, the causative agent of bacterial kidney disease (BKD). The
progeny of these females were purposely destroyed. As a result, only nine raceways were stocked with fish. The project decided to use the fish from an odd raceway for a predator avoidance training sub-experiment (these fish were subsequently acclimated and released from the Easton acclimation site).

1. Brood years 1997-2001: Optimum Conventional Treatment (OCT). Brood Years 2002-2004: Normal (High) growth. Brood Years 2005-2012: Normal feed at Cle Elum or accl. sites.
2. Brood years 1997-2001: Semi-natural Treatment (SNT). Brood Years 2002-2004: Slowed (Low) growth. Brood Year 2005, 2007-2012: saltwater transition feed at accl. Sites; 2014: BioPro vs BioVIT. Brood Year 2006: EWS diet at CESRF through May 3, 2007.
3. $\mathrm{CFJ}=$ Clark Flat; ESJ=Easton; JCJ=Jack Creek.
4. At the Jack Creek acclimation site only 4 of 6 raceways were stocked, and raceway 4 suffered mechanical failures resulting in the loss of about 20,000 OCT (control) fish.
5. High BKD incidence in adult broodstock reduced production to just 9 ponds (Clark Flat 1-2, Jack Creek, and Easton). Easton ponds were used for predator avoidance trained (PAT) fish and a single Cle Elum pond was spread between 6 ponds at Easton with crowders used to simulate pond densities for fish at other acclimation sites. These releases were excluded from mean pond density calculations by treatment.
6. At the Jack Creek acclimation site raceway 3 suffered mechanical failures resulting in the loss of about 45,000 high-growth (control) fish.

1. All fish released as subyearlings unless otherwise noted.
2. Includes Marion Drain facility acclimation

For smolt migration years 2000 to present, annual abundance estimates of juvenile smolts migrating downstream at Prosser Dam averaged 209,900 wild/natural spring Chinook, 331,200 CESRF-origin spring Chinook, 42,200 wild/natural-origin coho,
and 271,300 hatchery-origin coho (Table 9). These are the years for which our data and methods are considered most reliable. Juvenile passage estimates for earlier years are provided below under "Status and Trend of Juvenile Productivity"; however, the reader should be aware that we have less confidence in these data because we have refined data collection protocols and passage estimation methods over time. As the majority of fall Chinook smolt migrants are unmarked hatchery-origin fish, we provide only the gross abundance indices below under "Status and Trend of Juvenile Productivity". The reader is cautioned to pay particular attention to the factors complicating estimates of juvenile abundance and productivity described under "Status and Trend of Juvenile Productivity".

## Status and Trend of Juvenile Migration Survival to McNary Dam

Methods: For all species, releases of PIT tagged smolts provided a means to estimate smolt survival to McNary Dam. For most releases, PIT-tag detectors were located in or near the exit(s) from the release sites (monitoringresources.org 1558) and allowed estimation of the number of PIT-tagged fish leaving the release sites. To estimate the survival of smolts detected leaving the release sites that eventually pass McNary Dam,
the proportion of PIT-tagged smolts detected leaving the release sites that were later detected at McNary Dam was divided by McNary Dam's detection efficiency. The estimated detection efficiency was the number of smolts detected passing dams downstream of McNary that were previously detected passing McNary divided by the total number of smolts passing the downstream dams, whether or not the smolts were previously detected at McNary. Our methods are described in detail in Appendix C and are generally consistent with Sandford and Smith (2002) and with monitoringresources.org methods 623 and 1536. We used weighted logistic or weighted least squares analysis of variance to analyze differences in survival metrics and indices between various release sites, years and treatments. Additional detail, results and discussion are provided in Appendices D (spring Chinook), E (coho), and F (summer-run Chinook). There were no PIT-tagged releases of fall-run Chinook in 2020; the latest results for this species were presented in Appendix G of Fiander et al. (2019).

## Results and Discussion:

For spring Chinook, we compared survivals to McNary Dam of CESRF hatchery-and natural-origin PIT-tagged smolts released into the Roza Dam bypass and migrating downstream of Roza Dam contemporaneously on or after March 16. This date was selected because CESRF fish were not allowed to begin volitional emigration from the acclimation sites until March 15 . Approximately $81 \%$ of natural-origin spring Chinook smolts PIT-tagged and released at Roza since 1999 migrated downstream of Roza Dam prior to March 16 (derived using queries of PTAGIS database 7/12/2013). Natural and hatchery-origin smolts contemporaneously migrating past Roza from March 16 on are referred to as "late" migrants. Survival from Roza Dam to McNary Dam was better for late-migrating natural-origin relative to hatchery-origin spring Chinook smolts and for late-migrating relative to early-migrating natural-origin smolts (Figure 11; Appendix D).

For coho, we estimated survival from acclimation site release to McNary Dam based on life stage, brood source, location, and timing of the releases (Appendix E). The average survival probability of Coho Salmon smolts from the release sites to McNary Dam in 2020 was $47.14 \pm 5.78 \%$, which was higher than estimates for the past three years. The higher survival rate for 2020 migration is at least partly due to release location because most of the tagged smolts in 2020 were released at Prosser Dam in the lower Yakima River. In other years, smolts were also released from several locations upstream from Prosser Dam, with correspondingly lower survival rates. The survival rate of smolts to McNary Dam was higher for the Eagle Creek-stock releases ( $52.6 \pm 7.4 \%$ ) than for Yakima-origin release ( $41.1 \pm 10.1 \%$ ). In 2019 and 2020, there was no release of the Washougal stock. For the last 6 migration years (2015-2020), Coho parr were released at different locations from May to October. Release site-to-

McNary survival of the parr releases was higher for the population released in August ( $14 \% \pm 0.20$ ) and followed by the group of July releases ( $3.1 \% \pm 0.40$ ) and then June releases ( $1 \% \pm 0.4$ ).

Figure 11. Box plot showing the 5-year average survival probabilities of natural-origin (Natural) and hatchery-origin (Hatchery) spring Chinook Salmon smolts (S. Pandit, Appendix D). A. is the comparison of Late hatchery- and natural-origin smolts; and $B$. is the comparison between Early- and Late-migrating natural-origin smolts.

Juvenile survival rates to McNary Dam for summer-run Chinook varied by year over migration years from 2010 through 2020 (Figure 12). The highest average annual survival rate was in $2011(40.15 \% \pm 1.94 \%)$ and the lowest was in 2015 $(0.73 \% \pm 0.47 \%)$. For 2020, the average survival rate from the combined release locations to McNary Dam was $14.7 \% \pm 2.5 \%$, which was a substantial improvement over 2018-2019. The relationship between the average of May and June river flow measured below Prosser Dam and the annual survival rate (release location to McNary Dam from 2009 through 2020) was strong and statistically significant $\left(\mathrm{r}^{2}=0.54, \mathrm{p}=0.01\right)$ indicating that survival rate was a function of river flow in May and June. Higher flow in these months results in higher survival of juvenile Summer Chinook outmigrants. We also found that the relationship of size to survival rate from Prosser to McNary dams was similar for April and May releases, but that releases in June depressed the Prosser-to-McNary survival rate over the entire range of fish sizes. A complete report of our study of juvenile outmigration survival of

Yakima Basin Summer Chinook to Prosser and McNary dams is provided in Appendix F.

Figure 12. Average annual survival rate (release to McNary Dam) of juvenile Summer Chinook smolts migrating from 2010 through 2020 (S. Pandit, Appendix F).

The data indicate that there are substantial sources of juvenile mortality limiting survival of smolts migrating from release sites in the Yakima River basin. The YKFP is working with partners in multiple forums to implement habitat restoration and water resource management projects that address factors limiting survival and productivity (see Yakima Subbasin, Recovery, and Integrated plans).

## Status and Trend of Juvenile Productivity (smolt-to-adult returns)

## Methods:

Smolt abundance passage estimates at Prosser and the methods used to derive them were described above. For spring Chinook, adult return estimates to the Yakima River mouth were derived using Prosser and Roza adult abundance and harvest data (described in other sections of this report and in Appendix B) and run reconstruction techniques (Appendix B). For coho, we used Prosser adult abundance.

Adult fall Chinook returning to the Yakima Basin consist of hatchery-origin returns from releases at and above Prosser Dam and natural-origin returns from fish spawning naturally in the Yakima River. Due to fiscal, physical, logistical, and policy considerations, only a small proportion of hatchery-origin releases have been externally marked. Therefore, it is impossible at present to know the origin of unmarked adult fall Chinook counted at Prosser. Additional marking is proposed for hatchery-origin releases as part of the Master Plan (Yakama Nation 2019). To derive rough smolt-to-adult return indices for fall Chinook, aggregate (marked and unmarked combined) smolt passage estimates for the age-3, -4 , and -5 components for a given return year were averaged and the aggregate adult passage estimate for that return year was divided by this average smolt passage estimate. For example, the "Prosser Average Smolts" for adult return year 1988 is the average of marked and unmarked Prosser smolt estimates for juvenile migration years 1983-1985.

We also queried the PTAGIS database for PIT-tagged summer- and fall-run Chinook and Coho that were released in the Yakima Subbasin in recent years and produced McNary Dam juvenile (smolt) to Bonneville Dam adult SAR indices using juvenile detections at or downstream of McNary and adult detections at or upstream of Bonneville Dams.

## Results:

Table 10. Estimated smolt passage at Chandler and smolt-to-adult return indices (Chandler smolt to Yakima R. mouth adult) for Yakima Basin wild/natural and CESRF-origin spring Chinook.

1. Mean flow (cfs) approaching Prosser Dam March 29-July 4 of juvenile migration year. In high flow years (flows at or $>5000 \mathrm{cfs}$ ) operation of the Chandler smolt sampling facility may be precluded during portions of the outmigration. Data courtesy of U.S. BOR hydromet.
2. Aggregate of Upper Yakima, Naches, and American wild/natural populations.
3. Estimated smolt-to-smolt (release from upper Yakima River acclimation sites to Chandler) survival for CESRF juveniles.
4. Includes combined age-3 through age-5 returns. CESRF adult returns and smolt-to-adult survival values are understated relative to wild/natural values since these figures are not adjusted for differential harvest rates in mark selective fisheries in marine and lower Columbia River fisheries.
5. Available data were not sufficient to estimate juvenile flow-entrainment and passage of wild/natural fish.
6. Data for most recent year are preliminary; return data do not include age-5 adult fish.

Table 11. Average combined hatchery- and natural-origin smolt counts at Prosser for fish returning at age-3, -4 , and -5, combined adult returns to Prosser Dam of all age classes, and estimated Prosser smolt-to-adult return indices for Yakima River fall-run Chinook for adult return years 1988-2020.

${ }^{\text {a }}$ PIT-tagged fish released as parr in brood year 2003, 2004 (Upp. Yak.), and 2013 (Naches) experienced very poor $(<1 \%)$ survival to McNary Dam as juvenile smolts and were omitted from this analysis.

## Discussion:

Calculation of smolt-to-adult survival rate indices for Yakima Basin anadromous salmonids are complicated by the following factors:

1) Smolt accounting at Prosser is based on statistical expansion of Chandler smolt trap sampling data using available PIT-detection and flow data and estimated Chandler entrainment rates. Chandler smolt passage estimates are prepared primarily for the purpose of comparing relative marked versus unmarked passage estimates and not for making survival comparisons. While these Chandler smolt passage estimates represent the best available data, there may be a high degree of error associated with
these estimates due to inherent complexities, assumptions, and uncertainties in the statistical expansion process. Therefore, these estimates are subject to revision.
2) Large numbers of Yakima Basin salmonid releases (all CESRF spring Chinook) are adipose-fin clipped and subjected to higher harvest rates than unmarked wild/natural fish in marine and Columbia River mark-selective fisheries. No adjustments have yet been made in the above SAR estimates to account for differential harvest rates in these mark-selective fisheries.
3) Due to issues such as water diversion permitting, size required for tagging, and allowing sufficient time for acclimation, release time for many hatchery-origin juveniles (including all CESRF spring Chinook) may be delayed relative to their wild counterparts. For example, spring Chinook from the CESRF are not allowed to volitionally migrate until at least March 15 of their smolt outmigration year; however, juvenile sampling observations at Roza Dam indicate that a substantial number of wild/natural juveniles migrate downstream during the summer, fall, and winter months prior to their smolt outmigration year. Analysis of juvenile migrant PIT detections at Roza Dam (PTAGIS queries run $7 / 12 / 2013$ ) indicated that approximately $81 \%$ of natural-origin spring Chinook migrated downstream of Roza in the fall or winter as juveniles (before CESRF fish would have the opportunity). Comparison of SAR data for non-contemporaneously migrating juveniles may be invalid.

Given these complicating factors, Tables 10-14 present available smolt-to-adult survival indices for Yakima River spring and summer/fall Chinook and coho. Because of the complexities noted above, these data are useful for analysis of trends but should not be used as direct citations of, or for comparisons of marked and unmarked, smolt-to-adult survival rates. The reader is encouraged to contact Yakama Nation technical staff to discuss these and other issues prior to any use of these data or any other estimation of Yakima Basin SARs that may be available through data obtained from public web sites such as RMPC, PTAGIS, DART, FPC or others.

Substantial juvenile mortality of subyearling releases of summer- and fall-run Chinook occurs in the Yakima River between their release sites and McNary Dam (Neeley 2012b). Strategies have been proposed to address limiting factors (YSFWPB 2004) and improve survival of these releases (Yakama Nation 2019). As these strategies are implemented, we expect SARs for summer- and fall-run Chinook to improve substantially from the estimates provided in Table 11 (Yakama Nation 2019). Additional discussion and results for Yakima Basin spring Chinook SARs are presented in Appendix B.

## Status and Trend of Spatial Distribution (Redd Counts)

Methods: Regular foot and/or boat surveys (monitoringresources.org methods 30, $131,285,1508)$ were conducted within the established geographic range for each species (this is increasing for coho as acclimation sites are located upriver and as the run increases in size). Redds were individually marked during each survey and carcasses were sampled to collect egg retention, scale sample, sex, and body length information and to check for possible experimental marks. River conditions vary from year to year and preclude complete accounting, especially for fall Chinook and Coho. Other agencies (WDFW, Pacific Northwest National Laboratory, and private contractors) have also conducted foot, boat, or aerial surveys for fall Chinook redds in the Yakima River Basin and we have attempted to incorporate available information from those surveys here.

## Results:

## Discussion:

Spatial distribution of spring Chinook spawners has increased as a result of acclimation site location, salmon homing fidelity and more fully seeding preferred spawning habitats (Dittman et al. 2010). Redd surveys in the Teanaway River conducted annually by Yakama Nation staff since 1981 demonstrate the benefits of reintroducing salmonids into underutilized habitat (Figure 14). The Jack Creek acclimation site began releasing CESRF spring chinook in 2000, with the first age-4 females returning from these releases in 2002. Redd counts in this tributary have increased from a pre-supplementation average of 3 redds per year to a post supplementation average of 55 redds per year. The proportion of natural-origin carcasses increased from less than one percent in 2002 (when CESRF fish first returned to the natural spawning grounds) to $42 \%$ in 2006 when the progeny of the 110 redds produced in 2002 (virtually $100 \%$ of which were produced by CESRForigin fish) returned. These data clearly indicate that naturally-spawning CESRF spring Chinook were successful in returning natural-origin adults back to the Teanaway River. However, redd counts in the Teanaway River remain at or below pre-supplementation levels in some years, including 2018, indicating that habitat factors (primarily low late-summer and fall season flows) continue to deter returning fish and these fish are likely spawning in nearby mainstem and tributary reaches more conducive to survival of progeny (Fast et al. 2015).

Fall Chinook redd distribution in the Yakima River Basin appears to be experiencing a major transition in recent years. Historical redd survey data indicates that a substantial number of fall Chinook spawned below Prosser Dam in the lower Yakima River. However, from 2003-present, an average of approximately 80 percent (range 62 to 90 percent) of surveyed fall Chinook redds have been located above Prosser Dam (Figure 16). Biologists and habitat experts in the subbasin at least partially attribute this change in spawning distribution to the invasion of water stargrass (see Wise et al. 2009) in the lower 43 miles of the Yakima River. With the reintroduction of summer run Chinook, the Yakama Nation is expanding the distribution of summer/fall run Chinook spawners and redds into the middle reaches of the Yakima Basin between the town of Wapato upstream to the confluence with the Tieton River in the Naches subbasin and to Roza Dam in the Upper Yakima subbasin (Figures 1 and 15; Yakama Nation 2012). Summer-run Chinook have now spawned naturally in these habitats since 2013 after an absence of over 40 years.

Coho redd counts and spawner distribution have increased substantially since reintroduction efforts began (Table 16 and Figure 17). Many redds in the mainstem were located intermixed with fall chinook redds, tucked under cut banks or were found in side channels. Tributary redd enumeration and identification continues to be accurate due to the fall low water levels, improving interagency cooperation, and relatively good weather. One of the overall goals during the present implementation phase (Phase II) of the coho program is to evaluate the transition of redds from the mainstem river into historic tributaries. With the beginning of Phase II of the Coho Program we observed large increases in tributary spawning, with an annual average exceeding 200 redds counted in tributaries since 2004 (Table 16). Although, there were large numbers of potential spawners in 2014 ( $\sim 9,000$ females), river conditions were very unfavorable for finding redds. Winter anchor ice in early December kept surveys to a minimum. This was followed by winter freshets that reduced visibility in the Naches River to the point where visibility was near zero. However, the stability of low water conditions in 2015 might have contributed to good survival of coho eggs from the 2014-2015 spawning season. The 2020 redd count was difficult to perform because of the ongoing pandemic, but we did observe an increase in the overall redd counts for coho (Table 16). Coho continue to volunteer into many tributaries, and the fidelity of adults from summer parr plants has shown good results.

Adult Coho plants have also been used to evaluate the feasibility of increasing fish abundance in several tributaries. To determine the spawning success and effects on resident trout of these adult outplants, an intensive monitoring program was conducted in Taneum Creek for brood/spawn years 2007-2014. The results of this evaluation indicate that Coho spawned successfully and have the potential to produce large numbers of returning adult offspring per smolt that survive to McNary Dam as
juveniles (Table 17). The total biomass of all salmonids in the stream increased and there were no discernable impacts to resident trout (Temple et al. 2012, 2017). Adult coho were not planted in 2019 and 2020. However, there are plans for adult out plants in 2021.

## Status and Trend of Diversity Metrics

## Methods:

Diversity metrics collected for the Cle Elum Supplementation and Research Facility spring Chinook program in the Upper Yakima River include parameters relating to: eggs (e.g., egg size, KD at emergence, emergence timing, etc.), juveniles (growth and survival, migration timing, fish health, etc.), and adults (size at age, sex composition, migration timing, etc.). Methods for monitoring the spring Chinook program were documented in: the YKFP Monitoring Plan (Busack et al. 1997), the project's "Supplementation Monitoring Plan" (Chapter 7 in 2005 annual report on project genetic studies), and numerous manuscripts in the published literature (see Results and References).

Diversity metrics for returning adult summer/fall Chinook and coho collected at the Prosser Dam denil fish trap include sex ratios, lengths, and weights (monitoringresources.org methods 454, 1454, 1548, 1549, 1551, 4008, 4041). We also queried the PTAGIS database for PIT-tagged summer- and fall-run Chinook that were released in the Yakima Subbasin in recent years and used PIT-detection data at Bonneville Dam for upstream migrants to estimate age composition and run timing of returning fish.

## Results and Discussion:

A detailed presentation of current results for the spring Chinook monitoring program (YN-collected data) are included in Appendix B of this report and are discussed in greater detail in the annual report(s) for WDFW-companion project 1995-064-25. Generally, we have detected small, but significant differences between hatchery- and natural-origin fish in some juvenile and adult traits. Results in the published literature include: Busack et al. (2007), Knudsen et al. (2006, 2008), Larsen et al. (2004, 2006, 2010, 2013), and Pearsons et al. (2009).

Sex ratios, lengths, and weight data for fall Chinook and coho salmon sampled at the Prosser denil adult sampling facility from 2001-present are presented in Tables 18-21. Age composition of summer- and fall-run Chinook are presented in Table 22 and run timing in Figure 18. In addition, preliminary results of some diversity metrics relating to the effort to reestablish a natural spawning coho population in the Yakima Basin were published in Bosch et al. (2007). That study observed divergence in some diversity traits between hatchery- and natural-origin fish suggesting that some renaturalization can be detected in just a few generations after outplanting of hatcheryorigin fish in the wild.

${ }^{1} 10$ of $154(6.5 \%)$ of detections occurred about 90 days post-release in adult ladders at Bonneville Dam and were assumed to be age- 1 returns. However, only 2 of these 10 were confirmed as upstream detections based on later detections at dams upstream of Bonneville. The other 8 detections at Bonneville could have been late-migrating juveniles.

Figure 18. Adult return timing at Prosser Dam of PIT-tagged summer- and fall-run Chinook reared at the Marion Drain and Prosser Hatcheries and released as subyearlings, pooled for return years 2009-2018.

## Habitat Monitoring

While the majority of YKFP habitat activities in the Yakima Basin are addressed in a separate project (1997-051-00), we are monitoring stream sediment loads associated with the operation of dams and other anthropogenic factors (e.g. logging, agriculture and road building) under this contract as sediment loads can affect survival of salmonids (see description and references here and here).

## Status and Trend of Fine Sediment

Methods: Representative gravel samples (McNiel core samples, monitoring resources 1504) were collected from various reaches in the Little Naches and Upper Yakima Rivers in the fall of 2020. Each sample was analyzed to estimate the percentage of fine or small particles present $(<0.85 \mathrm{~mm})$. The Washington State Timber, Fish, and Wildlife program established guidelines that specify the impacts that estimated sedimentation levels can have on salmonid egg-to-smolt survival. These impact guidelines will inform future analyses of "extrinsic" factors on natural production in the Yakima Basin.

## Results and Discussion:

## Little Naches

A total of 106 McNiel core samples were collected and processed from 9 spawning reaches in the Little Naches drainage this past year. Pyramid Creek has not been sampled since 2009 when the main road going into this reach was decommissioned. Other means to access this sampling site is needed. With this year's monitoring work, the data set for the Little Naches drainage now covers a time period of 36 years for the two historical reaches, and 29 years for the expanded sampling area that includes several tributary streams.

The average percent fine sediment less than 0.85 mm for the entire Little Naches drainage in 2020 was $7.3 \%$ which is the lowest watershed average observed on record (Figure 19). The overall trend remains downward and similar trends can be seen when looking at individual reach conditions over the longer term monitoring period since 1992.

The overall average fine sediment found in spawning substrate remains relatively low and should lessen mortality on incubating eggs and alevins. The reduced rate of fine sediment found can be partially attributed to less anthropogenic disturbance occurring in the watershed in recent years, other than recreational activity. Timber harvest activity and road building has been minimal for several years. Landowners have also improved roads and trails to reduce sediment delivery.

Further, enhanced stream protection measures have been instituted through the Northwest Forest Plan and the Central Cascades Habitat Conservation Plan for over 20 years. These factors have likely helped reduce fine sediment inputs to the stream system. However recreational activity, such as dispersed camping sites and off-road vehicle use near streams, continues to be a concern. Sediment delivery, bank erosion, and loss of riparian vegetation from recreational use have been observed in some localized areas.

Figure 19. Overall Fine Sediment ( $<0.85 \mathrm{~mm}$ ) Trends with $95 \%$ confidence bounds in the Little Naches River Drainage, 1992-2020.

## South Fork Tieton

One reach on the South Fork Tieton River (in the vicinity of Minnie Meadows) has been sampled in the past by the U.S. Forest Service. To the best of our knowledge this reach has not been sampled since 2015. This stream reach typically receives significant bull trout spawning activity and the monitoring efforts provide valuable information on their spawning conditions. Average fine sediment in this reach was $8.9 \%$ in 2015, matching the previous low observed in 1999, and is well below the mean for sediment levels for the 17 years that were sampled (Figure 20).

## Upper Yakima

A total of 60 samples were collected and processed from the Upper Yakima River drainage this past year ( 5 reaches, 12 samples from each reach). The same reaches (Stampede Pass, Easton, Camelot to Ensign Ranch, Elk Meadows, and Cle Elum) have been sampled annually for the past 24 years. The 24 -year trend in average percent fine sediment less than 0.85 mm for the combined Upper Yakima drainage remains downward, with 2020 being among the four lowest years on record (Figure 21).

Figure 20. Fine Sediment Trends in the South Fork Tieton River, 1999-2015. Note: Data for 2007 were collected from only 1 Riffle. Data courtesy of U.S. Forest Service.

Figure 21. Overall average percent fine sediment ( $<0.85 \mathrm{~mm}$ ) in spawning gravels of the Upper Yakima River, 1997-2020.

## Summary

We continue to observe a general decreasing trend in average fine sediment levels in the Little Naches and Upper Yakima drainages. Increases observed in 20162019 in both drainages may have been due to effects from the large fires the region has experienced in recent years. Overall, the generally low rates of fine sediment should be conducive for egg and alevin survival and should favor salmonid spawning success.

The results of the USFS sampling in the South Fork Tieton River were also low over a 17 -year sampling period. These conditions should be favorable for early life history survival of bull trout.

Detailed field data including additional tables and graphs for samples collected in the upper Yakima and Naches basins can be obtained from Jim Matthews, fisheries biologist for the Yakama Nation (matj@yakamafish-nsn.gov).

## Harvest Monitoring

## Marine and Mainstem Columbia Fisheries

Methods: We evaluated recoveries of coded-wire tags (CWTs) and PIT tags in out-of-basin fisheries using queries of regional mark information system (RMIS) and PIT Tag Information System (PTAGIS) databases. We coordinated with agencies responsible for harvest management (WDFW, ODFW, USFWS, CRITFC, etc.) to estimate the harvest of target stocks. We reviewed reports produced annually by the Pacific Fisheries Management Council (marine) and the U.S. v Oregon Technical

Advisory Committee (mainstem Columbia) to evaluate estimated harvest or exploitation rates on comparable stocks in these fisheries.

For spring Chinook, additional information was employed that is not readily available for fall Chinook and coho. Standard run reconstruction techniques (Appendix B) were employed to derive estimates of harvest from the Columbia River mouth to the Yakima River mouth for spring Chinook. Data from databases maintained by the U.S. $v$ Oregon Technical Advisory Committee were used to obtain harvest rate estimates downstream of the Yakima River for the aggregate Yakima River spring Chinook population and to estimate passage losses from Bonneville through McNary reservoirs. These data, combined with the Prosser Dam counts and estimated harvest below Prosser, were used to derive a Columbia River mouth run size estimate and Columbia River mainstem harvest estimate for Yakima spring Chinook.

## Results:

1. Preliminary.

Figure 22. Distribution of coded-wire tag recoveries of Yakima Basin summer/fall run Chinook releases in marine, mainstem Columbia River, and Yakima Basin fisheries. Data retrieved from the regional mark information system (RMIS) for brood year 1997-2007 recoveries.

Recovery data for Yakima River-origin coho are presently limited because few fish have been coded wire-tagged until recent years. We will continue to collect and analyze CWT-recovery data from regional databases and will report this information in the future. 'All H Analyzer' (AHA) modeling for Master Planning purposes assumed that natural- and hatchery-origin Yakima River coho have an exploitation rate of approximately 40 and 60 percent, respectively (Yakama Nation 2019). These estimates include coho caught in marine, Columbia River and Yakima River fisheries.

## Discussion:

Based on available CWT information, harvest managers have long assumed that Columbia River spring Chinook are not harvested in any abundance in marine fisheries as their ocean migration does not generally overlap either spatially or temporally with the occurrence of marine fisheries (TAC 1997). Harvest recoveries of CESRF spring Chinook as reported to RMIS to date appear to confirm this, as marine harvest apparently accounts for only about $0-3 \%$ of the total harvest of Yakima Basin spring Chinook (Table 23). Adult returns of spring Chinook from the CESRF appear to be making substantial contributions to Columbia Basin fisheries (Table 24).

Yakima Basin summer/fall Chinook are harvested in marine fisheries from Alaska to southern Oregon, and in Columbia River fisheries from the mouth to the Hanford Reach (Figure 22). Approximately 71\% of harvest recoveries from Yakima Basin fall Chinook releases for brood years 1997-2007 occurred in marine (44\%) and mainstem Columbia ( $27 \%$ ) fisheries. Out-of-basin harvest rates have not been estimated
specifically for Yakima Basin summer/fall run Chinook, but the 1982-89 brood year average ocean fisheries exploitation rate for mid-Columbia River summer/fall Chinook was $39 \%$, with a total exploitation rate of $68 \%$ estimated for the same years (PSC 1994). Chapman et al. (1994) estimated that the 1975-87 brood year mean exploitation rate for fall Chinook released from Priest Rapids Hatchery was $64 \%$. Harvest rates of these stocks in U.S. fisheries since the mid-1990s have been reduced due to Endangered Species Act (ESA) management concerns as these stocks are intermixed with ESA-listed Snake River fall Chinook populations (NMFS 1999a-d and 2000a-c). It is assumed that Yakima River summer/fall run Chinook are harvested at the same rate in these fisheries as other mid-Columbia River summer/fall Chinook stocks.

## Yakima Subbasin Fisheries

Methods: The two co-managers, Yakama Nation and WDFW, are responsible for monitoring their respective fisheries in the Yakima River. Each agency employs fish monitors dedicated to creel surveys and/or fisher interviews at the most utilized fishing locations and/or boat ramps. From these surveys, standard techniques are employed to expand fishery sample data for total effort and open areas and times to derive total harvest estimates. Fish are interrogated for various marks. Methods are consistent with monitoringresources.org methods 404 and 960.

## Results:

1. Harvest rate is the total Yakima Basin harvest as a percentage of the Yakima River mouth run size.
2. Includes estimate of post-release mortality of unmarked fish.

## Discussion:

Adult returns of spring Chinook from the CESRF have substantially increased fishing opportunity for all fishers in the Yakima Basin (Table 25) and returned recreational fisheries to the Basin after a 40 -year absence. This has contributed to improved relationships between all the Basin's stakeholders and increased opportunities for collaboration.

Recreational fishers enjoy a successful annual fall Chinook fishery situated primarily near the mouth of the Yakima River (Table 26). Tribal fishers harvest a substantial, but unquantified number of Yakima Basin-destined fall Chinook (Figure 22) and coho in commercial gillnet fisheries in the Zone 6 fishing area. Because of the quantity and relatively higher quality of fall Chinook and coho available to tribal fishers in Zone 6 Columbia and Klickitat River fisheries, Yakima River tribal harvest is typically at or near zero even though regulations allowing fall season fisheries in the Yakima River are propagated annually by the Yakama Nation.

## Hatchery Research

## Effect of Artificial Production on the Viability of Natural Fish Populations

WDFW is addressing some critical uncertainties (see Columbia River Basin Research Plan and Critical Uncertainties for the Columbia River Basin Fish and Wildlife Program) related to genetic and ecological interactions under project 1995-064-25. We are working jointly with WDFW to address the following additional fish propagation uncertainties:
1.2. Can hatchery production programs meet adult production and harvest goals (integrated and segregated) while protecting naturally spawning populations?
1.4. What is the magnitude of any demographic benefit or detriment to the production of natural-origin juveniles and adults from natural spawning of hatchery-origin supplementation adults?
1.5. What are the range, magnitude and rates of change of natural spawning fitness of integrated (supplemented) populations, and how are these related to management rules including the proportion of hatchery fish permitted on the spawning grounds, and the proportion of natural origin adults in the hatchery broodstock?

## Methods:

The YKFP began a spring Chinook salmon hatchery program at the CESRF near Cle Elum on the upper Yakima River (river kilometer 297, measuring from the confluence with the Columbia River; Figures 1 and 23) in 1997. This program is a supplementation effort targeting the upper Yakima River population and is designed to test whether artificial propagation can be used to increase natural production and harvest opportunities while limiting ecological and genetic impacts (RASP 1992). It is an integrated hatchery program (Mobrand et al. 2005) because only natural-origin brood-stock are used and returning hatchery-origin adults are allowed to spawn in the wild. The program employs "best practice" hatchery management principles (see Cuenco et al. 1993, Mobrand et al. 2005) including reduced pond densities, strict disease management protocols, random brood-stock selection, and factorial mating (Busack and Knudsen 2007) to maximize effective population size. Fish are reared at the central facility, but released from three acclimation sites located near the central facility at: Easton approximately 25 km upstream of the central facility, Clark Flat about 25 km downstream of the central facility, and Jack Creek about 12 km upstream from the Teanaway River's confluence with the Yakima River (Figure 23). The CESRF collected its first spring Chinook brood-stock in 1997, released its first fish in 1999, and age-4 adults have been returning since 2001. The first generation of offspring of CESRF and wild fish spawning in the wild returned as adults in 2005. The program uses the adjacent, un-supplemented Naches River population as an environmental and wild control system.

To evaluate demographic benefits for spring Chinook, we compared redd count and natural-origin adult return data for the supplemented Upper Yakima and unsupplemented (control) Naches populations using a Before/After Control/Impact (BACI) analysis (Stewart-Oaten et al. 1986; Smith et al. 1993). For redd counts, the before period was defined as 1981 to 2000 and the after period as 2001 to present (hatchery-origin age-4 adults first returned to integrate with natural-origin fish on the natural spawning grounds in 2001). The first natural-origin returns of age-4 fish from these integrated population redds did not occur until 2005, so the pre- and postsupplementation (before/after) periods for natural-origin return evaluation were defined as 1982 to 2004 and 2005 to present, respectively. The spring Chinook findings described below were published in Fast et al. (2015). We are working with WDFW to incorporate additional out-of-basin control populations in this evaluation and these results will be considered for publication at a later date.

To evaluate fitness parameters for an integrated spring Chinook population, we used methods described in Knudsen et al. (2008), Schroder et al. (2008, 2010, and 2012) and Waters et al. (2015; discussed further below under Hatchery Reform). For coho,
we conducted preliminary evaluation of both demographic benefits and some fitness parameters using methods described in Bosch et al. (2007).

Figure 23. Map of the Yakima River Basin, Cle Elum Supplementation and Research Facility (CESRF) locations, and timeline of the spring Chinook supplementation program.

## Results:

Figure 24. Spring Chinook redd counts in the supplemented Upper Yakima (red bar) relative to the unsupplemented Naches (control; blue bar) for the pre- (1981-2000) and post-supplementation (2001-2020) periods.

Figure 25. Natural-Origin returns of Spring Chinook in the supplemented Upper Yakima (red bar) relative to the un-supplemented Naches (control; blue bar) for the pre- (1982-2004) and post-supplementation (20052020) periods.

## Discussion:

Supplementation has increased spring Chinook redd abundance in the Upper Yakima relative to the Naches control system (Figure 24). Redd counts in the postsupplementation period (2001-2020) increased in the supplemented Upper Yakima ( $+74 \% ; \mathrm{P}=0.041$ ) but the change observed in the un-supplemented Naches control system relative to the pre-supplementation period (1981-2000) was not significant $(+20 \% ; \mathrm{P}=0.398)$. As noted above, spatial distribution of spring Chinook has also increased as a result of supplementation with dramatic increases in redd abundance observed in the Teanaway River (Figure 14) in some years.

Changes in mean natural-origin return abundance in the post-supplementation period (2005-2020) relative to the pre-supplementation period (1982-2004) were not significant in either the supplemented upper Yakima River ( $-5.5 \%$; $\mathrm{P}=0.83$; Figure 25) or the unsupplemented Naches River system ( $-24.6 \%$; $\mathrm{P}=0.32$; Figure 25). We have already noted that limiting factors appear to be inhibiting natural productivity (see status and trend of adult productivity) throughout the Yakima Basin.

With respect to spring Chinook fitness parameters we found the following. The relationships between reproductive traits and body length were not significantly altered by a single generation of hatchery exposure. However, because hatchery females had smaller body sizes, the distributions of linked traits, such as total gamete mass and fecundity, differed by as much as 0.6 SD , probably resulting in some fitness loss. Our data support the idea that a single generation of state-of-the-art conservation hatchery propagation can produce fish with reproductive traits similar to those of wild fish, given comparable body size (Knudsen et al. 2008). No differences were detected in the egg deposition rates of wild and hatchery origin females, but pedigree assignments based on microsatellite DNA showed that the eggs deposited by wild females survived to the fry stage at a $5.6 \%$ higher rate than those spawned by hatchery-origin females (Schroder et al. 2008). Behavior and breeding success of wild and hatchery-origin males were found to be comparable (Schroder et al. 2010). Large anadromous males produced $89 \%$, jacks $3 \%$, yearling precocious $7 \%$, and sub-yearling precocious $1 \%$ of the fry in our tests suggesting that large anadromous males generate most of the fry in natural settings when half or more of the males present on a spawning ground use this life history strategy (Schroder et al 2012). For additional detail on Spring Chinook findings, see Fast et al. (2015). Finally, in addition to the relative reproductive success (RRS) results reported by Schroder et al. (2008 and 2010) for artificial spawning channel studies, we are also working with our project collaborators at WDFW and CRITFC to evaluate RRS for all integrated hatchery- and natural-origin spawners above Roza Dam for brood years 2007-2011 (see https://www.cbfish.org/Document.mvc/Viewer/P159280 for the latest progress report on this project). Genotyping for this work has been completed and we are working to publish findings in 2021.

The YKFP is presently studying the release of over 1.0 million coho smolts annually from acclimation sites in the Naches and Upper Yakima subbasins. These fish are a combination of in-basin production from brood-stock collected in the vicinity of Prosser Dam plus out-of-basin stock generally reared at Willard or Eagle Creek National Fish Hatcheries and moved to the Yakima Subbasin for final rearing and release. Monitoring of these efforts to re-introduce a sustainable, naturally spawning coho population in the Yakima Basin have indicated that coho returns averaged over 5,600 fish from 1997-2020 (an order of magnitude improvement from the average for years prior to the project) including estimated returns of wild/natural coho averaging over 800 fish annually since 2001 (Figure 4). Coho re-introduction research has demonstrated that hatchery-origin coho, with a legacy of as many as 10 to 30 generations of hatchery-influence, can reestablish a naturalized population after as few as 3 to 5 generations of outplanting in the wild (Bosch et al. 2007). The project is working to further develop a locally adapted brood-stock and to establish specific release sites and strategies that optimize natural reproduction and survival.

## Effectiveness of Hatchery Reform

Hatcheries have long been a part of the fisheries landscape in the Pacific Northwest with programs originally designed to provide abundant returns for harvest in river ecosystems that were becoming increasingly exploited to serve human needs (Lichatowich 1999). Historically, hatchery programs were designed to release a specified number of juveniles from a central facility, and adult survivors, after providing many fish for harvest during their marine and freshwater migrations, would return to swim-in ladders and adult holding ponds at that same facility to spawn successive generations. Over the past two decades or more, such programs have been the subject of much scientific study regarding risks, such as domestication, they pose to natural populations if these fish spawn in the wild.

The concepts of supplementation and hatchery reform, where hatchery programs could be (re)designed to serve conservation as well as harvest purposes, first began to appear in regional discussions and the literature in the late 1980s and early 1990s (e.g, RASP 1992; Cuenco et al. 1993). In Mobrand et al. (2005) and Paquet et al. (2011), the Hatchery Scientific Review Group (HSRG) described in more scientific detail several principles that should guide integrated (conservation-oriented) hatchery programs which purposefully allow fish to spawn in the wild (note that virtually all of the HSRG recommendations were designed into the integrated CESRF program described above). The HSRG reports also recommended that traditional, harvestoriented hatchery programs should be segregated as much as possible from natural populations to minimize risks by limiting the number of returning fish that escape to natural spawning grounds.

YKFP efforts to monitor and evaluate hatchery reform focus on the CESRF spring Chinook program which was designed explicitly for this purpose from its inception (BPA 1996). To the extent that is practical, we will evaluate similar metrics for the summer/fall run Chinook and coho programs and publish those results in future reports as the Master Plan (Yakama Nation 2019) is implemented and the programs mature over time.

In addition to the integrated (supplementation-S) hatchery program described above for the CESRF, this facility also introduced a segregated "hatchery control" (HC) program in 2002 as recommended by independent scientific review. To protect the integrity of the integrated program evaluation described above, returning HC line fish were either harvested or trapped and removed at the Roza Adult Monitoring Facility (RAMF); no HC line fish were allowed to escape to the spawning grounds (determination of fish origin was based on a differential marking strategy for $S$ and HC fish; unmarked fish were presumed wild). CESRF-project scientists hypothesized
that HC-line fish, which use only returning hatchery-origin fish as brood source, would increasingly diverge in phenotypic and genetic characteristics from wild (WC or wild control) fish with increasing generations of hatchery influence, whereas S-line fish, which use only wild or natural-origin fish for brood source, would remain relatively close in characteristics to wild fish (Figure 26). These hypothetical outcomes were based on hatchery reform theory which suggests that, by using only wild or natural-origin parents to spawn successive generations of fish in the hatchery environment, mean fitness of an integrated population in the natural environment can be maintained relatively close to that of a wild population (Mobrand et al. 2005).

> DOMESTICATION HYPOTHETICAL OUTCOMES

Figure 26. Hypothetical outcomes of trait divergence (domestication effects) over time for a segregated (hatchery-control or HC) line of fish, compared to an integrated (supplementation or S) line of fish and a wild (wild-control or WC) line of fish (D. Fast, Yakama Nation).

This section reports on our efforts to evaluate the effectiveness of hatchery reform measures implemented in the CESRF program.

## Methods:

Methods for enumerating natural- and CESRF-origin fish at Roza Dam were described above (Status and Trend of adult abundance) and in Knudsen et al. (2006). Methods for evaluating genetic differentiation between the wild founding, integrated, and segregated populations at the CESRF were described in Waters et al. (2015).

A recently developed parameter to monitor the mean fitness of an integrated population in the natural environment is called Proportionate Natural Influence (PNI). PNI is an approximation of the rate of gene flow between the natural environment and the hatchery environment (Busack et al. 2008). The equation describing PNI is

$$
\mathrm{PNI}=\frac{\mathrm{pNOB}}{\mathrm{pNOB}+\mathrm{pHOS}}
$$

where pNOB is the proportion of natural-origin brood-stock and pHOS is the proportion of hatchery-origin spawners. We evaluated PNI for the CESRF program using a pNOB value of 1.0 as only natural-origin fish were used for the integrated program's broodstock.

## Results and Discussion:

For CESRF integrated program return years 2001-2020, PNI averaged $65 \%$ while pHOS averaged $53.6 \%$ (Table 28). As stated in the introduction to this report and in the final Environmental Impact Statement for the Yakima Fisheries Project (BPA 1996), one of the explicit purposes of the project is to test the assumption that new artificial propagation or hatchery reform techniques (Cuenco et al. 1993, Mobrand et al. 2005) can be used to increase natural production without causing significant impacts to existing natural populations. Therefore, it has always been the intent of this project to purposely allow integrated hatchery-origin fish to escape to the natural spawning grounds, i.e., we intentionally maintained a relatively high pHOS rate. Even with a high pHOS relative to recommendations, PNI for the CESRF integrated program remained in the "low hatchery influence for conservation of natural populations" category described by the HSRG (Paquet et al. 2011).

The project will continue to monitor PNI considering factors such as: policy input regarding controlling the number and types of fish allowed to escape to natural spawning areas, meeting overall production goals of the project, guidance from the literature relative to percentage of hatchery fish on the spawning grounds with fitness loss, considerations about what risk is acceptable in a project designed to evaluate impacts from that risk, and the numerous risk containment measures already in place in the project. The State of Washington is using mark-selective fisheries in the lower Columbia River and, when possible, in the lower Yakima River in part as a tool to manage escapement proportions. In 2011, the project implemented an effort to transfer some returning hatchery-origin CESRF adults from Roza Dam to Lake Cle Elum for the purpose of returning marine derived nutrients and salmon to the watersheds that feed the lake. These measures will also increase PNI in the major
spawning areas of the Upper Yakima Basin. Additional adaptive management measures will be considered when and if monitoring and evaluation indicates a need.

Table 28. Escapement (Roza Dam counts less brood-stock collection and harvest above Roza) of natural(NoR) and hatchery-origin (HoR) spring Chinook to the upper Yakima subbasin, 1982 - present.

| Year | Wild/Natural (NoR) |  |  | CESRF (HoR) |  |  | Adults | Total Jacks | Total | pHOS ${ }^{1}$ | $\mathrm{PNI}^{1}$ |

| Mean ${ }^{3}$ | 2,321 | 328 | 2,648 | 2,221 | 679 | 2,794 | 4,171 | 922 | 5,093 | 53.6\% | 64.8\% |

1. Proportionate Natural Influence equals Proportion Natural-Origin Brood-stock (PNOB; 1.0 as only NoR fish are used for supplementation line brood-stock) divided by PNOB plus Proportion Hatchery-Origin Spawners (PHOS).
This is a rough estimate since Roza counts are not available for 1991.
2. For NoR columns, mean of 1997-present values. For all other columns, mean of 2001-present values.

Both the CESRF integrated and segregated programs have now proceeded for several generations and we can evaluate actual outcomes relative to the hypothetical outcomes given in Figure 26 above. Results were presented in Waters et al. (2015) and empirically demonstrate that using managed gene flow (i.e, using only naturalorigin fish for brood stock) reduced genetic divergence over time in the CESRF integrated (S-line) fish compared to the segregated (HC-line; hatchery-origin parents) fish (Figure 27). The actual results are remarkably consistent with the projected outcomes in Figure 25 demonstrating that there is considerable merit to the concepts behind hatchery reform. While some detractors of hatchery supplementation choose to highlight the differences the CESRF program has found between hatchery and natural-origin fish such as those documented in Knudsen et al. (2006 and 2008), it is important to note that integrated hatchery-origin fish were never expected to be identical to wild fish (Figure 26), but rather similar enough to increase demographic abundance of natural spawners while minimizing risk, which is exactly what the results to date for this project demonstrate (Fast et al. 2015; Koch et al. 2017). Additional evaluation is required before definitive answers to key biological cost and benefit questions relative to using this type of management over the long-term will be known with scientific certainty (Fraser 2008). The YKFP is continuing its collaboration with University of Washington and NOAA scientists to further evaluate and associate genetic divergence results from Waters et al. (2015) with the phenotypic trait analyses in Knudsen et al. (2006 and 2008).

Figure 27. Estimated genetic divergence (variation) for integrated (INT blue), segregated (SEG red), and wild founder (black) spring Chinook in the CESRF program after 4 parental-generations of the hatchery program ( $\mathbf{P 1}=\mathbf{1 9 9 8}, F 1=2002, F 2=2006, F 3=2010, F 4=2014$; updated from Figure 4 in Waters et al. 2015).

Additional information and results from the CESRF program are provided in Appendix B and in Fast et al. (2015).

## Predation Management and Predator Control

## Avian Predation Index

Avian predators are capable of significantly depressing smolt production. The loss of wild spring Chinook salmon juveniles to various types of avian predators has long been suspected as a significant constraint on production and could limit the success of supplementation. Therefore, a long-standing objective of the YKFP has been to monitor, evaluate, and index the impact of avian predation on annual salmon and steelhead smolt production in the Yakima Subbasin. Accurate methods of indexing avian predation across years have been developed.

## Methods:

## River Reach Surveys

The spring river surveys included six river reaches (Table 29) and were generally consistent with avian point count methods described in monitoringmethods.org method 1151. The survey accounts for coverage of approximately 70 miles of the lower portion of the Yakima River.

Table 29. Avian predation river reach survey start and end locations and total reach length.

| Survey Name | River Mile Start | River Mile End | Survey Distance |
| :---: | :---: | :---: | :---: |
| Parker | 107.0 | 93.8 | 13.2 |
| Granger-Emerald | 85.3 | 66.5 | 18.8 |
| Mabton- Prosser | 60.6 | 48.5 | 12.1 |
| Below Prosser | 46.4 | 36.6 | 9.7 |
| Chandler Power Plant -Benton | 36.6 | 30.2 | 6.5 |
| Below Horn Rapids-Van Giesen | 16.8 | 9.4 | 7.4 |

All river reach surveys were conducted by a two-person team from a 16 -foot drift boat or 12-foot raft. Surveys began between 8:00 am and 9:00 am and lasted between 2 to 6 hours depending upon the length of the reach and the water level. All surveys were conducted while actively rowing the drift boat or raft downstream to decrease
the interval of time required to traverse the reach. One person rowed the boat while the other person recorded piscivorous birds encountered.

| Great Egret | Ardea alba | GREG |
| Hooded Merganser | Lophodytes cucullatus | HOME |
| Bald Eagle | Haliaeetus leucocephalus | BAEA |
| Osprey | Pandion haliaetus | OSPR |
| Caspian Tern | Sterna caspia | CATE |

All birds detected visually or aurally were recorded, including time of observation, species, and sex and age if distinguishable. Leica 10x42 binoculars were used to help observe birds. All piscivorous birds encountered on the river were recorded at the point of initial observation. Most birds observed were only mildly disturbed by the presence of the survey boat and were quickly passed. Navigation of the survey boat to the opposite side of the river away from encountered birds minimized escape behaviors. If the bird attempted to escape from the survey boat by moving down river a note was made that the bird was being pushed. Birds being pushed were usually kept in sight until passed by the survey boat. If the bird being pushed down river moved out of sight of the survey personnel, a note was made, and the next bird of the same species/age/sex to be encountered within the next 1000 meters of river was assumed to be the pushed bird. If a bird of the same species/age/sex was not encountered in the subsequent 1000 meters, the bird was assumed to have departed the river or passed the survey boat without detection, and the next identification of a bird of the same species/age/sex was recorded as a new observation.

## Avian Predator Hotspot Surveys

Two "hotspots" of avian predators have been identified within the Lower Yakima River (Figure 28). These "hotspots" consist of an area below the Chandler fish bypass outfall pipe and below Wanawish Dam. To include data about these hotspots weekly bird counts will be conducted at each of these "hotspots" by YN personnel and BOR personnel. Data will be single day counts of piscivorous birds during the early morning.

## Acclimation Site Surveys

Three Spring Chinook acclimation sites in upper Yakima River (Clark Flat, Jack Creek, and Easton) were surveyed for piscivorous birds from 2004 through 2018 (Figure 1). Surveys were conducted between January 23 and June 10, though dates varied for each site. Three surveys were conducted at the Spring Chinook sites each day, at 8:00 am, 12:00 noon, and 4:00 pm. Surveys were conducted on foot. All piscivorous birds within the acclimation facility, along the length of the artificial acclimation stream, and 50 meters above and 150 meters below the acclimation stream outlet, into the main stem of the Yakima River or its tributaries, were recorded.

Figure 28. Avian Predator Survey Locations.

## Results and Discussion:

River Reach Surveys

Thirteen different piscivorous bird species were observed on the Yakima River. These included: American White Pelican, Bald Eagle, Black-crowned Night Heron, Belted Kingfisher, Caspian Tern, Common Merganser, Double-crested Cormorant, Forster's Tern, Great Egret, Great Blue Heron, Gull species (California and Ringbill), Hooded Merganser, and Osprey. With the exception of the Forster's Tern, 12 of the species have been observed in most survey years. Graph Data (Figure 29) for river reach surveys represents Avian Predator totals by reach of the lower Yakima River (surveys below Wapato Dam). The total avian predators in the Parker Reach by week are represented in (Figure 30) and numbers increased as river flows decreased. The avian predator counts within the Parker, Granger, Below Prosser, Benton, and Lower Yakima reaches are represented in the bar graphs by their survey acronyms (Figures 31-35).

The Osprey, Great Blue Heron, Common Merganser, and Belted Kingfisher were observed within all six reaches in 2019 while American White Pelicans and Double Crested Cormorants have also been observed in these six reaches in prior years. Common Mergansers were the most abundant Avian Predators in the upper surveyed reaches of the river. The abundance of the Common Merganser in the upper Yakima River in 2019 and all previous years monitored suggest they are the top avian predator for the upper river while American White Pelicans are dominant at Parker and Granger (Figures 31-32).

Gull numbers in the lower Yakima River decreased in 2016 and this trend continued into 2018. In 2019, gulls were again abundant showing increased numbers below Prosser Dam and in the Benton reach at the end of May and in June. Double Crested Cormorants numbers remained consistent in 2019. DCCO numbers remain a concern due to nest takeover of Great Blue Heron Rookeries in various areas along the Yakima River along their high capacity for consuming salmon smolts. Monitoring of the Double Crested Cormorant on the river and in rookeries will be a priority in upcoming years as the Army Corp of Engineers culls and removes breeding habitat at the estuary of the Columbia River in efforts to reduce juvenile salmon predation. These actions may result in displacement and searching out of new habitat for the Cormorants and lead to impacts on salmon in other rivers and basins. The American White Pelican numbers remain consistently high in the lower Yakima River. In the Yakima River pelicans can be seen in groups of over 100 in the Wapato Reach of the river along the borders of the Yakama Indian Reservation.

Figure 32. Granger Reach Avian Predator Species Counts.

Figure 33. Below Prosser Avian Predator Species Counts.

Figure 34. Benton Reach Avian Predator Species Counts.

Figure 35. Lower Yakima Reach Avian Predator Species Counts.

## Hotspot Surveys

Avian predator surveys were conducted at the Chandler fish bypass pipe (river mile ~46; Figure 36) and Wanawish Dam (river mile ~18.5; Figure 37) hotspots. In 2019 there was an increase in avian predators at both hotspot locations. At Chandler the species diversity stayed the same, where at Wanawish dam there was a decrease in diversity. Only three species were observed at Wanawish in 2019, American White Pelican, Double Crested Cormorant, and Gulls.

Figure 36. Avian Predator Counts at Chandler "hotspot".

Figure 37. Avian Predator Counts at Wanawish Dam "hotspot".

## Acclimation Sites Surveys

At the three Spring Chinook salmon acclimation sites in the upper Yakima River and its tributaries piscivorous bird surveys were conducted over a 3-5 month period in the winter and spring of 2019. The most common species of birds observed at acclimation sites were Bald Eagle, Belted Kingfisher, Common Merganser, Great Blue Heron, Great Egret, and Osprey. Using the assumption that birds frequenting
acclimation ponds are only consuming acclimating juvenile salmon, an average consumption rate can be determined. The average consumption rate can be calculated using the average number of birds at each site, daily energy requirements of the birds and the average size of juvenile salmon.

It was estimated that these bird species together consumed 786 juvenile Chinook at Clark Flat (Table 31). Great Blue Herons had the highest consumption rate, consuming 545 juvenile Chinook. At Easton, it was estimated that 375 juvenile Chinook were consumed. Great Blue Herons and Bald Eagles had the highest consumption rates. Great Blue Herons consumed 122 juvenile Chinook and Bald Eagles consumed 188 juvenile Chinook. Only Belted Kingfishers and Common Mergansers were observed at Jack Creek. It was estimated that they consumed 151 juvenile Chinook. Common Mergansers consumed 137 juvenile Chinook. In 2018, these bird species together consumed 950 juvenile Chinook at Clark Flat, 339 juvenile Chinook at Easton and 961 juvenile Chinook at Jack Creek.

## Fish Predation Index and Predator Control

Fish predators are also capable of significantly depressing smolt production. Thus the YKFP has a long-established objective to monitor, evaluate, and manage the impact of piscivorous fish on annual smolt production of Yakima Subbasin salmon and
steelhead. By indexing the mortality rate of upper Yakima spring Chinook attributable to piscivorous fish in the lower Yakima River, the contribution of in-basin predation to variations in hatchery- and natural-origin spring Chinook smolt-to-adult survival rate can be deduced.

Based on YKFP and WDFW studies of piscivorous fish in the Yakima River Basin (Fritts and Pearsons 2004, 2006, 2008), it was determined that management of the piscivorous fish populations in the area is necessary to improve survival of juvenile salmonids. Initial steps were taken in 2009 to identify locations that would be suitable for a multi-pass removal population study. In early 2010, the YKFP began initial study checks to determine management and study goals for piscivorous fish. Presence and absence of piscivorous fish was determined through electro-fishing various sections of the Yakima River to determine temporal and spatial trends of each species of piscivorous fish. On March 1, 2013, the Washington Fish and Wildlife Commission adopted numerous changes to sport fishing rules, including the elimination of catch restrictions for non-native predators.

## Methods:

Data was collected on piscivorous fish from six electrofishing sites within the Yakima River (Figure 38). Sites were sampled via boat electrofishing through time to assess spatial and temporal patterns of fish abundance and distribution. Each sampling segment was defined by river features of dams and boat launches. The partitioned sample locations consist of four ten mile surveys, one four-mile survey, and one six mile survey (Table 32). Total river mile distance of the combined Yakima River surveys is 50 miles. Survey locations were marked by GPS unit (Garmin GPSmap 78; Garmin International, Olathe, Kansas). After marking sampling reaches, we sample weekly beginning April 2nd and ending June 22nd (dates may vary depending on river stage). (Fish Predators Schei, monitoring methods 47), (Predator Reduction Mclellan, monitoring methods 438).

Sampling was conducted using three different types of vessels and electrofisher; 1. For five of the Yakima River surveys sampling were conducted using a Smith Root SR16H Electrofishing boat equipped with the 7.5 GPP electrofishing unit powered by a $6,000-\mathrm{W}$ Kohler boat generator in; 2. For the Yakima River survey below Prosser sampling was conducted with a 13 foot raft equipped with a smith root $1.5-\mathrm{KVA}$ electrofisher powered by Honda EU2000i generator; 3. For the survey in the McNary pool sampling was conducted with a 16 foot aluminum jet boat equipped with a Smith Root VVP-15B electrofisher powered by a Honda EM3500S generator. Electrofishing settings were adjusted to continuous DC for an output of approximately 700 V and 9-12 A. Invasive species monitoring for the Yakima River will be used as an aid
for tracking changes in fish populations and abundance as the area experiences global climate change.

Figure 38. Fish Predator Survey Locations.
Table 32. Fish Predator Survey River Miles and Distances.

| Survey Name | River Mile Start | River Mile End | Survey Distance Miles |
| :---: | :---: | :---: | :---: |
| Parker | 106.1 | 96.1 | 10 |
| Granger | 85.3 | 75.3 | 10 |
| Above Prosser | 52.4 | 48.4 | 4 |
| Below Prosser | 46.4 | 40.4 | 6 |
| Benton | 31.1 | 21.1 | 10 |
| Lower Yakima | 13.8 | 3.8 | 10 |

Sampling was conducted continuously along river margins when possible. As river stage changes, limiting access to areas within survey segments, continuous electrofishing was not always possible. The start and endpoints of shocker operation within the segment at low river stages was marked, resulting in discontinuous, marked subsegments of electrofisher operation within each survey area.

Data collected during each sampling event consisted of:

- Water Temperature, Dissolved Oxygen, Specific Conductivity gathered by a HACH 30qd water multi-meter
- Water Turbidity gathered by a HACH TSS Handheld Instrument
- River CFS gathered from Bureau of Reclamation gaging stations
- Electrode start and end times
- Numbers and species (Table 33) of all fish observed and their size class greater than or less than 100 mm

At the start of each sampling event a small group of fish were caught and examined to insure that electro-fishing settings were not causing visible injuries. To further insure injuries to fish were minimized, sampling procedures by the National Marine Fisheries Service, "Guidelines for Electrofishing Waters Containing Salmonids Listed under the Endangered Species Act," were followed.

## Results and Discussion:

During surveys of 2018 to 2019 the highest abundance of non-native fish predators were found in the lower reaches of the Yakima River (Figure 39). Piscivorous fish were identified in all 6 survey reaches of the Yakima River. Smallmouth Bass and Channel Catfish were the fish predators found in the highest abundance. These two predators are often considered to be the top salmon predators in the lower Yakima River.

Northern Pike Minnow are the dominant piscivorous fish in the upper portion of the 2019 surveyed reaches of Yakima River (reaches above Prosser Dam). They were the fish predator found in the highest abundance in this area during electro-fishing surveys of 2019. Fish counts for all species observed during the 2019 surveys are given for all reaches in figures 40 through 45.

Figure 39. Fish Predator Counts by Reach and Species.

Figure 40. Parker Reach Fish Counts by Species.

Figure 41. Granger Reach Fish Counts by Species.

Figure 42. Above Prosser Dam Fish Counts by Species.

Figure 43. Below Prosser Dam Fish Counts by Species.

Figure 44. Benton Reach Fish Counts by Species.

Figure 45. Lower Yakima Reach Fish Counts by Species.

Large amounts of introduced fish predators inhabit the Lower Yakima River. Predator numbers tend to increase as time progresses in the spring and summer. Increases in predator abundance in 2019 showed significant correlation with increasing date (Figure 46). These increases also correspond with increasing water temperatures and decreasing river flows.

Figure 46. Total Count of Fish Predators below Prosser Dam.

Smallmouth Bass (SMB) have been found to exhibit a spike in abundance during their spawning periods in the Lower Yakima River. Spawning for Smallmouth Bass is typically between April 1 and July 1. This time period coincides with juvenile salmonid outmigration. This timing provides a readily available prey source for the adult spawning bass and their young recruits. Catch and catch per unit effort for adult Smallmouth Bass begins to rise in the May and June survey periods (Figure 47) as Smallmouth Bass migrate from the Columbia River into the Yakima River to spawn. A rise in catch in adults also correlates with a rise in Yakima River water temperature (Figure 48).

The rise and fall of SMB relative abundance may correlate with the water year of 2015 which produced extremely low flows and high water temperatures and the subsequent high water year in 2016, 2017, and 2018. It is the increase in water temperature in the lower Yakima River which is thought to create productive habitat for SMB. Overall
years there is increased catch success during the late summer and fall months and electro-fishing efforts are increased to maximize catch for managing numbers of SMB in the lower Yakima River. Current efforts to increase salmon populations target SMB populations for management in hopes to increase survival of juvenile salmon outmigration.

## Adaptive Management and Lessons Learned

As noted extensively throughout this report, this project is a collaborative effort involving many agencies, boards, and individuals. As such, project coordination and review of project standards and protocols occurs continually amongst tribal, state, federal, and local entities during normal day-to-day operations of the project. Project results are communicated broadly through the annual science and management conference, technical reports and peer-reviewed journal publications (see references and project-related publications), and via several related web sites described in Appendix A.

We support the principles established in Mobrand et al. (2005) and Paquet et al. (2011) that hatchery programs should be well-defined, scientifically defensible, and use informed decision making tools including adaptive management. Many of these principles were initially published in Cuenco et al. (1993) including specific recommended decision criteria, management protocols, release strategies, and risk management strategies for hatchery programs. We designed a number of these protocols and strategies into the CESRF program and they are clearly contributing to
the results documented here for the Upper Yakima River Basin spring Chinook populations.

Results to date from Yakama Nation supplementation and research efforts in the Yakima River Basin indicate several lessons that may be of broader application on the regional scale.

1. We need to be realistic. Can or should we expect to see "self-sustaining natural populations" in river systems that have been highly altered from their historical state due to ever-increasing human demands on shared resources? In the highly altered systems we live and work in today, hatchery programs provide a necessary means to ameliorate some of the effects of human population growth and development.
2. We need to be honest. Hatchery programs are not the cause of poor productivity. The historical record is replete with documentation (see Dompier 2005) that the region knew exactly what it was doing to natural salmon productivity when development of the region began to intensify with implementation of the Federal Columbia River Power System as early as the 1930s.
3. We need to be patient. Hatchery reform is a relatively new concept and results for longer term 20-25 year efforts such as the Idaho Supplementation Studies (ISS; Venditti et al. 2017) and CESRF program (Fast et al. 2015) are only now becoming available. These programs empirically support the idea that hatchery reform principles can provide the expected benefits.
4. While hatchery supplementation has demonstrated increases in natural production (increased redd and juvenile abundance), supplementation by itself cannot and was never intended to increase natural productivity. To accommodate expanding human population growth and resource demand, it is imperative that we continue and even increase habitat restoration actions to ensure that sufficient spawning and rearing habitat remains available to all naturally spawning fish.
5. Every subbasin, species, and study is unique, so we should not be surprised to see differing results from the many studies of hatchery effects that are ongoing. Researchers need to continue efforts to better understand the root causes of poor natural productivity and the extent to which hatchery programs effect productivity.
6. Evaluation of hatchery programs should include evaluation of environmental and other factors so that hatchery effects are properly reported.
7. Hatchery programs should be regularly evaluated at the local level using expertise across disciplines to collaboratively and iteratively develop appropriate solutions that address the unique problems and limiting factors encountered in each subbasin or tributary that hosts a hatchery program. In the Yakima Basin, this is achieved with the annual Yakima Basin Aquatic Science and Management Conference, and we use the results to evaluate existing goals, objectives, and strategies and to adaptively manage projects in response to new information.

## Appendix A: Use of Data \& Products

All data and findings should be considered preliminary until results are published in the peer-reviewed literature.

## Where will you post or publish the data your project generates?

## Fish Passage Center

Yakama Nation Fisheries website
RMIS - Regional Mark Information System
Columbia River DART
StreamNet Database
cbfish.org (see projects 1995-063-25 and 1988-120-25)
PTAGIS Website
Washington State SaSI
A system has been developed that serves Yakima Basin adult abundance and trap sampling (requires login) data for the Prosser and Roza data sets. This system can be accessed at: https://www.yakamafish-nsn.gov/fish-data.

Describe the accessibility of the data and what the requirements are to access them?

- Prosser and Roza dam daily count and trap sample (requires login) data https://www.yakamafish-nsn.gov/fish-data.
- Integration of PIT and CWT release and recovery data with PTAGIS, RMIS, and Fish Passage Center databases (available to the public)
- BPA quarterly and annual reports (e.g., PISCES, available to the public via CBfish.org)
- NPCC project proposals (available to the public via nwcouncil.org)
- Yakima Basin conference presentations and project technical reports (available to the public)
- Yakima Basin Status and Trends Annual Reports (available to the public)

Additional data is available in the main body and other appendices of this report and by email contact through the data managers (Yakima Basin, contact Bill Bosch, bill bosch@yakama.com; Klickitat Basin, contact Michael Babcock, mbabcock@ykfp.org). Project data managers continue to participate in the Coordinated Assessments process to develop pilot exchange templates for adult and juvenile abundance and productivity parameters. However, we continue to believe that the best way to prioritize our data management work load is to develop databases to store the status and trend data we have been collecting over many years as well as the web tools necessary to access these data in downloadable format. The system we have developed to share Prosser and Roza dam daily count and trap sample data is an example of the progress we are making towards this end.

Contract Numbers: 56662 REL 214

## Acknowledgments

Monitoring and evaluation efforts for the Cle Elum Supplementation and Research Facility (CESRF) and Yakima River spring Chinook salmon are the result of a cooperative effort by many individuals from a variety of agencies including the Yakama Nation Fisheries Program (YN), the Washington Department of Fish and Wildlife (WDFW), the United States Fish and Wildlife Service (USFWS), the National Oceanic and Atmospheric Administration Fisheries department (NOAA Fisheries) as well as some consultants and contractors.

The core project team includes the following individuals: Mark Johnston, Bill Bosch, Shubha Pandit, Andrew Matala, Daylen Isaac, Chris Frederiksen, Michael Porter, Joe Hoptowit, and a number of technicians from the YN; Charles Strom and a number of assistants from the CESRF; Anthony Fritts, Gabe Temple, Christopher Johnson, and a number of assistants from the WDFW; the USFWS for fish health related analyses; and Don Larsen, Andy Dittman, and assistants from NOAA Fisheries. The technicians and assistants are too numerous and varied to mention each by name (and risk leaving some out). However, their hard work in the field is the source of much of the raw data needed to complete this report. We sincerely appreciate their hard work and dedication to this project.

We would especially like to thank former members of the Yakima/Klickitat Fisheries Project, Dave Fast, David Lind, Paul Huffman, Bruce Watson, Joel Hubble, Bill Hopley, Todd Pearsons, Steve Schroder, Curt Knudsen, Doug Neeley and Craig Busack. These individuals put in countless hours of hard work during the planning, design, and implementation of this project. Their contributions helped to lay a solid foundation for this project and our monitoring and evaluation efforts. Dan Barrett (retired) served as the manager of the CESRF from 1997-2002. He helped to lay a solid foundation for the critical work done day in and day out at the Cle Elum facility.

We also need to recognize and thank the Yakama Nation and WDFW for their continued support, and the Columbia River Inter-Tribal Fish Commission, the University of Idaho, the Pacific States Marine Fisheries Commission, Mobrand, Jones, and Stokes, and Central Washington University for their many contributions to this project including both recommendations and data services.

This work is funded by the Bonneville Power Administration (BPA) through the Northwest Power and Conservation Council's (NPCC) Fish and Wildlife Program. Michelle O'Malley is BPA's contracting officer and technical representative (COTR) for this project. David Byrnes and Patricia Smith preceded Michelle in this position and contributed substantially to the project over the years.

#### Abstract

Historically, the return of spring Chinook salmon (Oncorhynchus tshawytscha) to the Yakima River numbered about 200,000 fish annually (BPA, 1990). Spring Chinook returns to the Yakima River averaged fewer than 3,500 fish per year through most of the 1980s and 1990s (less than $2 \%$ of the historical run size).

In an attempt to reverse this trend the Northwest Power and Conservation Council (formerly the Northwest Power Planning Council, NPPC) in 1982 first encouraged Bonneville Power Administration (BPA) to "fund the design, construction, operation, and maintenance of a hatchery to enhance the fishery for the Yakima Indian Nation as well as all other harvesters" (NPPC 1982). After years of planning and design, an Environmental Impact Statement (EIS) was completed in 1996 and the CESRF was authorized under the NPCC's Fish and Wildlife Program with the stated purpose being "to test the assumption that new artificial production can be used to increase harvest and natural production while maintaining the long-term genetic fitness of the fish population being supplemented and keeping adverse genetic and ecological interactions with non-target species or stocks within acceptable limits". The CESRF became operational in 1997. This project is co-managed by the Yakama Nation and the Washington Department of Fish and Wildlife (WDFW) with the Yakama Nation as the lead entity.

This report documents data collected from Yakama Nation tasks related to monitoring and evaluation of the CESRF and its effect on natural populations of spring Chinook in the Yakima Basin through 2020. This report is not intended to be a scientific evaluation of spring Chinook supplementation efforts in the Yakima Basin. Rather, it is a summary of methods and data (additional information about methods used to collect these data may be found in the main section of this annual report) relating to Yakima River spring Chinook collected by Yakama Nation biologists and technicians from 1982 (when the Yakama Nation fisheries program was implemented) to present. Data summarized in this report include:

- Adult-to-adult returns
- Annual run size and escapement
- Adult traits (e.g., age composition, size-at-age, sex ratios, migration timing, etc.)
- CESRF reproductive statistics (including fecundity and fish health profiles)
- CESRF juvenile survival (egg-to-fry, fry-to-smolt, smolt-to-smolt, and smolt-toadult)
- CESRF juvenile traits (e.g., length-weight relationships, migration timing, etc.)
- Harvest impacts

The data presented here are, for the most part, "raw" data and should not be used without paying attention to caveats associated with these data and/or consultation with project biologists. No attempt is made to explain the significance of these data in this report as this is left to more comprehensive reports and publications produced by the project. Data in this report should be considered preliminary until published in the peer reviewed literature.

## Introduction

## Program Objectives

The CESRF was authorized in 1996 under the NPCC's Fish and Wildlife Program with the stated purpose being "to test the assumption that new artificial production can be used to increase harvest and natural production while maintaining the long-term genetic fitness of the fish population being supplemented and keeping adverse genetic and ecological interactions with non-target species or stocks within acceptable limits". The CESRF became operational in 1997. The experimental design calls for a total release of 810,000 smolts annually from each of three acclimation sites associated with the facility (see facility descriptions). To minimize risk of over-collecting brood stock and to maintain lower pond rearing densities, the YKFP policy group took action in 2011 to create a release target range of 720,000-810,000 smolts for brood collection purposes. Female percentage, fecundity and survival rates are expected to result in releases between 720,000 and 810,000 smolts in most years. The first program cycle (brood years 1997 through 2001) also included testing new Semi-Natural rearing Treatments (SNT) against the Optimum Conventional Treatments (OCT) of existing successful hatcheries in the Pacific Northwest. The second program cycle (brood years 2002-2004) tested whether a slower, more natural growth regime could be used to reduce the incidence of precocialism that may occur in hatchery releases without adversely impacting overall survival to adult returns. Brood years 2005-2007 tested survival using different types of feed treatment. Subsequent broods have used a standard treatment in all raceways. With guidance and input from the NPCC and the Independent Scientific Review Panel (ISRP) in 2001, the Naches subbasin population of spring Chinook was established as a wild/natural control. A hatchery control line at the CESRF was also established with the first brood production for this line collected in 2002. Please refer to the project's "Supplementation Monitoring Plan" (Chapter 7 in 2005 annual report on project genetic studies) for additional information regarding these control lines.

## Facility Descriptions

Returning adult spring Chinook are monitored at the Roza adult trapping facility located on the Yakima River (Rkm 205.8). This facility provides the means to monitor every fish returning to the upper Yakima Basin and to collect adults for the CESRF program. All returning CESRF fish (adipose-clipped fish) are sampled for biological characteristics and marks and returned to the river with the exception of fish collected for broodstock, experimental sampling, and all hatchery control line fish. Through 2006, all wild/natural fish passing through the Roza trap were returned directly to the river with the exception of fish collected for broodstock or fish with metal tag detections which were sampled for marks and biological characteristics. Beginning in 2007, all wild/natural fish were sampled (as described above) and tissue samples were collected for a "Whole Population" Pedigree Study of Upper Yakima Spring Chinook (see related project 2009-009-00).

The CESRF is located on the Yakima River just south of the town of Cle Elum (rkm 295.5). It is used for adult broodstock holding and spawning, and early life incubation and rearing. Fish are spawned in September and October of a given brood year (BY). Fish are typically ponded in March or April of BY+1. The juveniles are reared at Cle Elum, marked in October through

December of BY+1, and moved to one of three acclimation sites for final rearing in January to February of BY+2. Acclimation sites are located at Easton (ESJ, rkm 317.8), Clark Flats near the town of Thorp (CFJ, rkm 266.6), and Jack Creek (JCJ, approximately 32.5 km north of Cle Elum) on the North Fork Teanaway River (rkm 10.2). Fish are volitionally released from the acclimation sites beginning on March 15 of BY+2, with any remaining fish "flushed out" of the acclimation sites by May 15 of $\mathrm{BY}+2$. The annual production goal for the CESRF program is 720,000 to 810,000 fish for release as yearlings at $30 \mathrm{~g} / \mathrm{fish}$ or 15 fish per pound (fpp) although size-at-release may vary depending on experimental protocols (see Program Objectives).

## Yakima River Basin Overview

The Yakima River Basin is located in south central Washington. From its headwaters near the crest of the Cascade Range, the Yakima River flows 344 km ( 214 miles) southeastward to its confluence with the Columbia River (Rkm 539.5; Figure 1).

Figure 1. Yakima River Basin.

Three genetically distinguishable populations of spring Chinook salmon exist in the Yakima basin: the American River, the Naches, and the Upper Yakima Stocks (Figure 1). The upper Yakima was selected as the population best suited for supplementation and associated evaluation and research efforts.

Local habitat problems related to irrigation, logging, road building, recreation, agriculture, and livestock grazing have limited the production potential of spring Chinook in the Yakima River basin. It is hoped that recent initiatives to improve habitat within the Yakima Basin, such as those being funded through the NPCC's fish and wildlife program, the Pacific Coastal Salmon Recovery Fund, and the Washington State salmon recovery fund, will: 1) restore and maintain natural stream stability; 2) reduce water temperatures; 3) reduce upland erosion and sediment delivery rates; 4) improve and re-establish riparian vegetation; and 5) re-connect critical habitats throughout the basin. These habitat restoration efforts should permit increased utilization of habitat by spring Chinook salmon in the Yakima basin thereby increasing fish survival and productivity.

## Adult Salmon Evaluation

## Broodstock Collection and Representation

One of the program's goals is to collect broodstock from a representative portion of the population throughout the run. If the total run size could be known in advance, collecting brood stock on a daily basis in exact proportion to total brood need as a proportion of total run size would result in ideal run representation. Since it is not possible to know the run size in advance, the CESRF program uses a brood collection schedule that is based on average run timing once the first fish arrive at Roza Dam. We have found that, while river conditions dictate run timing (i.e., fish may arriver earlier or later depending on flow and temperature), once fish begin to move at Roza, the pattern in terms of relative run strength over time is very similar from year to year. Thus a brood collection schedule matching normal run timing patterns was developed to assure that fish are collected from all portions of the run (Figure 2).

Figure 2. Mean spring Chinook run timing and broodstock collection at Roza Dam, 2011-2020.
Appendix B. Yakima River / CESRF Spring Chinook Salmon - Yakama Nation Data Summary 2020 Annual Report, July 16, 2021

Another program goal is to take no more than $50 \%$ of the wild/natural adult return to Roza Dam for broodstock. Given this goal and with a set brood collection schedule at Roza Dam, the project imposed a rule that no more than $50 \%$ of the fish arriving on any given day be taken for broodstock. Under-collection relative to the schedule is "carried over" to subsequent days and weeks. This allows brood collection to adjust relative to actual run timing and run strength. Performance across years with respect to these brood collection goals is given in Table 1. Since 2015, the spring Chinook return has been impeded by thermal barriers in the lower Yakima River as warmer air temperatures combined with reduced summer and fall flows have increased water temperatures. Mean daily water temperatures near Prosser (rkm 76 from the mouth of the Yakima R.) have exceeded $68^{\circ} \mathrm{F}$ on several days between June and September during these years (source U.S. BOR hydromet database). This may have caused a large number of fish to stray or be delayed in their migration above Roza Dam.

Table 1. Counts of wild/natural spring Chinook (including jacks), brood collection, and brood representation of wild/natural run at Roza Dam, 1997 - present.

| Year | Trap Count | Brood Take | Brood \% | Portion of run collected: ${ }^{1}$ |  |  | Portion of collection from: ${ }^{2}$ |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| 2012 | 2,924 | 374 | 12.8\% | 1.9\% | 12.3\% | 27.4\% | 1.1\% | 79.9\% | 19.0\% |
| 2013 | 2,784 | 398 | 14.3\% | 18.5\% | 13.0\% | 22.0\% | 9.5\% | 75.1\% | 15.3\% |
| 2014 | 4,168 | 384 | 9.2\% | 4.8\% | 8.6\% | 16.9\% | 2.3\% | 80.5\% | 17.1\% |
| 2015 | 3,962 | 442 | 11.2\% | 3.1\% | 8.2\% | 40.6\% | 2.0\% | 59.9\% | 38.1\% |
| 2016 | 2,712 | 376 | 13.9\% | 5.3\% | 14.8\% | 18.6\% | 2.5\% | 84.7\% | 12.9\% |
| 2017 | 1,711 | 382 | 22.3\% | 53.6\% | 19.0\% | 45.4\% | 11.4\% | 69.9\% | 18.7\% |
| 2018 | 827 | 294 | 35.6\% | 3.0\% | 33.7\% | 87.6\% | 0.3\% | 75.1\% | 24.6\% |
| 2019 | 703 | 312 | 44.4\% | 48.1\% | 46.3\% | 29.1\% | 8.3\% | 84.3\% | 7.3\% |
| 2020 | 958 | 427 | 44.6\% | 47.7\% | 48.1\% | 15.9\% | 4.9\% | 91.1\% | 4.0\% |

1. This is the proportion of the earliest, middle, and latest running components of the entire wild/natural run which were taken for broodstock. Ideally, this collection percentage would be equal throughout the run and would match the "Brood \%".
2. This is the proportion of the total broodstock collection taken from the earliest, middle, and latest components of the entire wild/natural run. Ideally, these proportions would match the definitions for early, middle, and late given in 3.
3. Early is defined as the first $5 \%$ of the run, middle is defined as the middle $85 \%$, and late as the final $10 \%$ of the run.

## Natural- and Hatchery-Origin Escapement

While the project does not actively manage for a specific spawning escapement proportion (natural- to hatchery-origin adults), we are monitoring the proportion of natural influence (PNI; Table 2). The project will adaptively manage this parameter considering factors such as: policy input regarding surplusing of fish, meeting overall production goals of the project, guidance from the literature relative to percentage of hatchery fish on the spawning grounds with fitness loss, considerations about what risk is acceptable in a project designed to evaluate impacts from that risk, and the numerous risk containment measures already in place in the project. The State of Washington is using mark-selective fisheries in the lower Columbia River and, when possible, in the lower Yakima River in part as a tool to manage escapement proportions. In 2011, the project initiated an effort to transfer some returning hatchery-origin CESRF adults from Roza Dam to Lake Cle Elum for the purpose of returning marine derived nutrients and salmon to the watersheds that feed the lake. This effort will also increase PNI in the major spawning areas of the Upper Yakima Basin. Natural- and hatchery-origin escapement to the upper Yakima Basin is given in Table 2. Wild/natural escapement to the Naches subbasin is given in Table 3.

Table 2. Escapement (Roza Dam counts less brood stock collection and harvest above Roza) of natural(NoR) and hatchery-origin (HoR) spring Chinook to the upper Yakima subbasin, 1982 - present.

| Year | Wild/Natural (NoR) |  |  | CESRF (HoR) |  |  | Adults | Total Jacks | Total | pHOS ${ }^{1}$ | PNI ${ }^{1}$ |

1. Proportion Natural Influence (including jacks) equals Proportion Natural-Origin Broodstock (pNOB; 1.0 as only NoR fish are used for supplementation line brood stock) divided by pNOB plus Proportion Hatchery-Origin Spawners (pHOS).
2. This is a rough estimate since Roza counts are not available for 1991.
3. For NoR columns, mean of 1997-present values. For all other columns, mean of 2001-present values.

## Adult-to-adult Returns

The overall status of Yakima Basin spring Chinook is summarized in Table 3. Adult-to-adult return and productivity data for the various populations are given in Tables 4-8 (Means are for 1988 to present).

Table 3. Yakima River spring Chinook run (CESRF and wild, adults and jacks combined) reconstruction, 1991-present.

1. River Mouth run size is the greater of the Prosser count plus lower river harvest or estimated escapement plus all known harvest and removals.
2. Estimated as the average number of fish per redd in the upper Yakima times the number of redds between the Naches confluence and Roza Dam.
3. Roza removals include harvest above Roza, hatchery removals, and/or wild broodstock removals.
4. Estimated escapement into the upper Yakima River is the Roza count, less harvest or broodstock removals above Roza Dam except in 1991 when Upper Yakima River escapement is estimated as the (Prosser count - harvest above Prosser - Roza subtractions) times the proportion of redds counted in the upper Yakima.
5. Naches River escapement was estimated as the Prosser count, less harvest above Prosser and the Roza counts.
6. Recent 10-year average (2011-2020).

Appendix B. Yakima River / CESRF Spring Chinook Salmon - Yakama Nation Data Summary

Estimated spawners for the Upper Yakima River are calculated as the estimated escapement to the Upper Yakima plus the estimated number of spawners in the Upper Yakima between the confluence with the Naches River and Roza Dam (Table 3). Total returns are based on the information compiled in Table 3. Age composition for Upper Yakima returns is estimated from spawning ground carcass scale samples for the years 1982-1996 (Table 11) and from Roza Dam brood stock collection samples for the years 1997 to present (Table 13). Since age- 3 fish (jacks) are not collected for brood stock in proportion to the jack run size, the proportion of age-3 fish in the upper Yakima for 1997 to present is estimated using the proportion of jacks (based on visual observation) counted at Roza Dam relative to the total run size.

Table 4. Adult-to-adult productivity indices for upper Yakima wild/natural stock.

| Brood Year | Estimated Spawners | Estimated Yakima R. Mouth Returns |  |  |  | Returns/ <br> Spawner |

1. The geometric mean jack (age-3) proportion of spawning escapement from 1999-2020 was 0.17.
2. Preliminary.

Appendix B. Yakima River / CESRF Spring Chinook Salmon - Yakama Nation Data Summary 2020 Annual Report, July 16, 2021

Estimated spawners for the Naches/American aggregate population (Table 7) are calculated as the estimated escapement to the Naches Basin (Table 3). Estimated spawners for the individual Naches and American populations are calculated using the proportion of redds counted in the Naches Basin (excluding the American River) and the American River, respectively (see Table 31). Total returns are based on the information compiled in Table 3. Age composition for Naches Basin age-4 and age-5 returns are estimated from spawning ground carcass scale samples (see Tables 9-12). The proportion of age-3 fish is estimated after reviewing jack count (based on visual observations) data at Prosser and Roza dams. Since sample sizes for carcass surveys in the American and Naches Rivers can be very low in some years (Tables 9 and 10), it is recommended that the data in Tables 5 and 6 be used as indices only. Table 7 likely provides the most accurate view of overall productivity rates in the Naches River Subbasin.

Table 5. Adult-to-adult productivity indices for Naches River wild/natural stock.

1. The geometric mean jack (age-3) proportion of spawning escapement from 1999-2020 was 0.09.
2. Preliminary.

Estimated spawners at the CESRF are the total number of wild/natural fish collected at Roza Dam and taken to the CESRF for production brood stock. Total returns are based on the information compiled in Table 3 and at Roza dam sampling operations. Age composition for CESRF fish is estimated using scales and PIT tag detections from CESRF fish sampled passing upstream through the Roza Dam adult monitoring facility.

Table 8. Adult-to-adult productivity for Cle Elum SRF spring Chinook.

| Brood | Estimated | Estimated Yakima R. Mouth Returns |  |  |  |  |
| :---: | :---: | ---: | ---: | ---: | ---: | ---: | Returns/

1. 357 or $48 \%$ of these fish were jacks.
2. Preliminary.
3. Geometric mean.

## Age Composition

Comparisons of the age composition in the Roza adult monitoring facility (RAMF) samples and spawning ground carcass recovery samples show that older, larger fish are recovered as carcasses on the spawning grounds at significantly higher rates than younger, smaller fish (Knudsen et al. 2003 and Knudsen et al. 2004). Based on historical scale-sampled carcass recoveries between 1986 and 2016 (there were no carcass recoveries in 2017 or 2018), age composition of American River spring Chinook has averaged $1,44,54$, and 1 percent age- $3,-4,-5$, and -6 , respectively (Table 9). Naches system spring Chinook averaged 2, 61, 36 and 0.5 percent age- $3,-4,-5$ and -6 , respectively (Table 10). The upper Yakima River natural origin fish averaged 8, 88, and 4 percent age- $3,-4$, and -5 , respectively (Table 11). While these ages are biased toward the older age classes, we believe the bias is approximately equal across populations and is a good relative indicator of differences in age composition between populations. The data show distinct differences with the American River population having the oldest age of maturation, followed closely by the Naches system and then the upper Yakima River which has significantly more age- 3 's, fewer age- 5 's and no age- 6 fish.

Appendix B. Yakima River / CESRF Spring Chinook Salmon - Yakama Nation Data Summary 2020 Annual Report, July 16, 2021

Carcasses from upper Yakima River CESRF origin fish allowed to spawn naturally have also been sampled since age-4 adults began returning in 2001. These fish averaged 13, 85 , and 1 percent age- $3,-4$, and -5 , respectively (Table 12) from 2001-2014 compared to 8,88 , and 4.3 percent respectively for their wild/natural counterparts in the upper Yakima for the same years (Table 11). The observed difference in age distribution between wild/natural and CESRF sampled on the spawning grounds may be due in part to the carcass recovery bias described above. A better comparison of age distribution between upper Yakima wild/natural and CESRF fish is from samples collected at Roza Dam which are displayed in Tables 13 and 14. However, it must be noted that jacks (age-3 males) were collected at Roza in proportion to run size from 1997 to 1999, but from 2000-present we have attempted to collect them at their mean brood representation rate (approximately $7 \%$ of the spawning population). Age- 3 females do occur rarely in the Upper Yakima population, but it is likely that the data in Table 13 slightly over-represent the proportion of age- 3 females due to human error associated with scale collection, handling, processing, and management and entry of these data.

Table 12. Percentage by sex and age of upper Yakima River CESRF spring Chinook carcasses sampled on the spawning grounds and sample size ( $\mathbf{n}$ ), 2001-present.

| Return Year | Males |  |  |  | Females |  |  |  | Total |  |  |

Appendix B. Yakima River / CESRF Spring Chinook Salmon - Yakama Nation Data Summary 2020 Annual Report, July 16, 2021

## Sex Composition

In the American River, the mean proportion of males to females in wild/natural carcasses sampled on the spawning grounds from 1986-2016 was 41:59 for age-4 and 33:67 for age- 5 spring Chinook (Table 15). In the Naches River, the mean proportion of males to females was 41:59 for age-4 and 27:73 for age-5 fish (Table 16). In the upper Yakima River, the mean proportion of males to females was 33:67 for age-4 and 23:77 for age-5 fish (Table 17). Collection of carcass samples from the spawning grounds throughout the Yakima Basin did not occur in 2017-2019 and very few carcasses were sampled in 2020.

For upper Yakima fish collected at Roza Dam for brood stock or research purposes from 1997-2020, the mean proportion of males to females was 38:62 and 35:65 for age-4 fish from the wild/natural and CESRF populations, respectively (Tables 19 and 20). For these same samples, the mean proportion of males to females was $35: 65$ and $41: 59$ for age- 5 fish from the wild/natural and CESRF populations (excluding years with very small age-5 sample sizes), respectively (Tables 19 and 20). For adult fish, the mean proportion of males to females in spawning ground carcass recoveries was substantially lower than the ratio found at RAMF (Tables 17 and 19), indicating that sex ratios estimated from hatchery origin carcass recoveries were biased due to female carcasses being recovered at higher rates than male carcasses (Knudsen et al, 2003 and 2004). Again, despite these biases, we believe these data are good relative indicators of differences in sex composition between populations and between years.

Sample sizes for Tables 15-20 were given in Tables 9-14. As noted earlier, few age-6 fish are found in carcass surveys and those that have been found were located in the American and Naches systems. The data indicate that age- 3 females may occasionally occur in the upper Yakima and, to a lesser extent, the Naches systems.

Table 15. Percent of American River wild/natural spring Chinook carcasses sampled on the spawning grounds by age and sex, 1986-present.

## Size at Age

Prior to 1996, samplers were instructed to collect mid-eye to hypural plate (MEHP) lengths from carcasses surveyed on the spawning grounds. From 1996 to present the method was changed and post-eye to hypural plate (POHP) lengths have been recorded. Mean POHP lengths averaged 39, 62, and 76 cm for age- 3 , -4 , and -5 males, and averaged 63 and 72 cm for age- 4 and -5 females, respectively, from carcasses sampled on the spawning grounds in the American River from 1996-2016 (Table 21). In the Naches River, mean POHP lengths averaged 42,60 , and 76 cm for age- $3,-4$, and -5 males, and averaged 61 and 72 cm for age- 4 and -5 females, respectively (Table 22). For wild/natural spring Chinook sampled on the spawning grounds in the upper Yakima River, mean POHP lengths averaged 44,60 , and 72 cm for age- $3,-4$, and -5 males, and averaged 59 and 69 cm for age- 4 and -5 females, respectively (Table 23). Beginning in 2012, carcass sampling in the Upper Yakima was scaled back considerably as large numbers of escaping fish are sampled at Roza Dam (Tables 27-28). From 2001-2020, CESRF fish returning to the upper Yakima have been generally smaller in size-at-age than their wild/natural counterparts (Tables 25-28).

Table 21. Counts and mean mid-eye (MEHP) or post-orbital (POHP) to hypural plate lengths (cm) of American River wild/natural spring Chinook from carcasses sampled on the spawning grounds by sex and age, 1987-present.

## Migration Timing

Wild/natural spring Chinook adults returning to the upper Yakima River have generally shown earlier passage timing at Roza Dam than CESRF spring Chinook (Figures 2 and 3).

Figure 3. Proportionate passage timing at Roza Dam of wild/natural and CESRF adult spring Chinook (including jacks), 2011-2020.

Table 29. Comparison of $5 \%$, median ( $\mathbf{5 0 \%}$ ) , and $95 \%$ passage dates of wild/natural and CESRF adult spring Chinook (including jacks) at Roza Dam, 1997-Present.

| Year | Wild/Natural Passage |  |  | CESRF Passage |  |  |

1. In 2000 all returning CESRF fish were age- 3 (jacks).
2. Mean daily water temperatures at Kiona (rkm 40 from the mouth of the Yakima R.) exceeded $70^{\circ} \mathrm{F}$ every day from May 21 to August 29, 2015 (source U.S. BOR hydromet database) causing delayed passage for late migrating fish.

## Spawning Timing

Median spawn timing for CESRF spring Chinook is earlier than that observed for wild/natural fish in the Upper Yakima River. These differences are due in part to environmental conditions and spawning procedures at the hatchery. It must also be noted that spawning dates in the wild are only a coarse approximation, derived from weekly redd counts not actual dates of redd deposition. A clear delineation of wild/natural spawn timing between subbasins is apparent, with American River fish spawning about 1 month earlier than Naches Basin fish which spawn about 2 weeks earlier than Upper Yakima fish.
Table 30. Median spawn ${ }^{1}$ dates for spring Chinook in the Yakima Basin.

| 2020 | 31-Aug | 23-Sep | 29-Sep | 22-Sep |
| Mean | 15-Aug | 12-Sep | 25-Sep | 22-Sep |

1. Approximately one-half of the redds in the system were counted by this date and one-half were counted after this date. For the CESRF, approximately one-half of the total broodstock were spawned by this date and one-half were spawned after this date.
2. Spawner surveys impacted by fires; especially in the Naches system.

## Redd Counts and Distribution

## Homing

A team from NOAA fisheries conducted studies to determine the spatial and temporal patterns of homing and spawning by wild and hatchery-reared salmon released from CESRF facilities from 2001 to 2010. These studies collected GPS information on each redd and carcass recovered within a survey reach. Carcass surveys were conducted annually in late-September to early October by NOAA personnel in cooperation with Yakama Nation survey crews over five different reaches of the upper Yakima River and recorded the location of each redd flagged and carcass recovered. For each carcass sex, hatchery/wild, male status (full adult, jack, mini-jack), and CWT location was recorded. Data collected on the body location of CWTs allowed the identification of the release site of some fish. While these studies were not designed to comprehensively map carcasses and redds in all spawning reaches in the upper watershed, preliminary data indicate that fish from the Easton, Jack Creek, and Clark Flat acclimation facilities had distinct spawner distributions. A more complete description of this project is available from NOAA fisheries and in this publication:

Dittman, A. H., D. May, D. A. Larsen, M. L. Moser, M. Johnston, and D. Fast. 2010. Homing and spawning site selection by supplemented hatchery- and naturalorigin Yakima River spring Chinook salmon. Transactions of the American Fisheries Society 139:1014-1028.

## Straying

The regional PTAGIS (PIT tag) and RMIS (CWT) databases were queried in January 2021 to determine the number of CESRF releases not returning to the Yakima River Basin (RMIS CWT data are incomplete for the most recent years). For adult (age-3, -4, or -5) PIT tagged fish, a stray is defined as detection at an out-of-basin facility in the Snake (Ice Harbor or Lower Granite) or Upper Columbia (Priest Rapids, Rock Island, or Wells) without a subsequent detection at Prosser or Roza Dam. For coded-wire tagged fish, a stray is generally defined as a tag recovery in tributaries of the Columbia River upstream (and including the Snake River Basin) of its' confluence with the Yakima River. Marked (adipose fin clipped) fish are occasionally found during carcass surveys in the Naches River system. All marked fish observed in spawning ground carcass surveys in the Naches Basin are assumed to be CESRF fish and are used to estimate in-basin stray rates.

Table 32. Estimated number of PIT- and CWT-tagged CESRF fish not returning to the Yakima River Basin (strays), and marked fish sampled during spawner surveys in the Naches Basin, per number of returning fish, brood years 1997-present.

[^4]
## CESRF Spawning and Survival

As described earlier, a portion of natural- and hatchery-origin (NoR and HoR, respectively) returning adults are captured at Roza Dam during the adult migration and taken to the CESRF for broodstock and/or research purposes. Fish are held in adult holding ponds at the CESRF from capture in the spring and summer until spawning in September through early October. All mortalities during the holding period are documented by sex and origin. During the spawning period data are kept on the number of males and females of each origin used for spawning or other purposes. All females have samples taken that are later evaluated for presence of BKD-causative agents. Eggs from females with high BKD-presence indicators are generally excluded (see Female BKD Profiles). Once fertilized, eggs are placed in holding troughs until shock time. Dead eggs are then sorted and hand-counted. All live eggs are machine counted, sorted into two lots per female (treatment and control) and placed into incubation (heath) trays. Using hand counts of egg samples from a subsample of female egg lots, WDFW staff determined that machine counts are biased and that the best approximation of live egg counts is given by the following equation:
$\left(\left(\frac{\text { no. eggs in subsample }}{\text { wt. of subsample }} *\right.\right.$ total egg mass wt $\left.) * 0.945\right)$-dead eggs
where
the first 3 parameters are from egg samples taken from females at spawn time, dead eggs are the number of dead or unfertilized eggs counted at shock time, and the 0.945 value is a correction factor from 1997 and 2000 WDFW studies.

Total egg take is calculated as the total number of live eggs, dead eggs, and all documented egg loss (e.g. spilled at spawn time, etc.). Heath trays are periodically sampled during incubation and dead fry are culled and counted. The number of live eggs less documented fry loss is the estimate of the number of fry ponded. Once fry are ponded, mortalities are counted and recorded daily during the rearing period. Fish are hand counted in the fall prior to their release as they are 100 -percent marked. This handcount less documented mortalities from marking through release is the estimate of smolts released. Survival statistics by origin and life-stage are given in Tables 33 and 34.

Table 33. Cle Elum Supplementation and Research Facility spawning and survival statistics (NoR brood only), 1997 - present.

1. Total collected minus total mortalities does not equal total spawned. This is because some fish are used in the spawning channel, some have been released back to the river, and some have not been used.
2. Includes jacks.
3. All documented egg loss at spawn time plus dead eggs counted at shock divided by the estimated total egg take.
4. Based on physical counts at mark time and all documented rearing mortality from ponding to release, except for BY2013 it is live eggs (est.) minus fry loss.
5. Approximately one-half of these were jacks, many of which were not used in spawning.
6. Approximately 45,000 smolts lost at Jack Creek due to frozen equipment in February, 2006.
7. EWOS feed treatment had high mortality and was discontinued in May 2007; resulted in lower survival to release.
8. Approximately 36,000 NoR (Table 33) and 12,000 HoR (Table 34) fish were culled in July 2009 to reduce pond densities; these fish were added back in to fry-smolt and live-egg-smolt survival calculations.

Continued from footnotes for Table 33 above.
9. Table 34 -- From 2002 to present this is the estimated total egg take from all HxH crosses. Due to the large surplus of eggs over the approximately 100 K needed for the HxH line, many surplus fry were planted in nearby land-locked lakes and some surplus eggs were destroyed.
10. Table 34 -- For only those HxH fish which were actually ponded.
11. The number of segregated, hatchery-control line brood raceways was increased from 2 to 4 for this brood due to overall brood shortages.

## Female BKD Profiles

Adults used for spawning and their progeny are tested for a variety of pathogens accepted as important in salmonid culture (USFWS Inspection Manual, 2003), on a population or "lot" basis. At the CESRF, and in the Columbia Basin it has been accepted that the most significant fish pathogen for spring Chinook is Renibacterium salmoninarum, the causative agent of Bacterial Kidney Disease (BKD). All adult females and 30-60 juveniles from each acclimation pond are individually tested for levels of Renibacterium salmoninarum using ELISA (Enzyme linked Immuno-sorbant Assay). ELISA data are reported annually to CESRF and YKFP staff for management purposes, eventual data entry and comparisons of ponds and rearing parameters. To date, no significant occurrences of other pathogens have been observed. Periodic field exams for external parasites and any signs of disease are performed on an "as needed" basis. Facility staff have been trained to recognize early signs of behavior changes or diseases and would report any abnormalities to the USFWS, Olympia Fish Health Center for further diagnostic work.

Adult females are ranked from 0 to 13 based on the relative amounts of BKD in the tissue samples of the tested fish. All BKD ranks below 5 are considered low risk for transferring significant BKD organisms through the egg to cause significant disease in progeny receiving proper care. The progeny of adults with BKD rank 6 are considered to be moderate risk and those with BKD rank 7 or greater are considered to be high risk. Given these data, the CESRF chose to rear only the progeny of females with a BKD rank of 6 or less through brood year 2001. Beginning with brood year 2002, the progeny of fish with BKD rank 6 (moderate risk) or greater (high risk) have not been used for production purposes at the CESRF. For additional information, see Appendix B.

Figure 4. Proportion of wild/natural females spawned at CESRF by BKD rank, 1997 - present.

## Fecundity

Fish collected at Roza Dam are taken to the CESRF for spawning and/or research purposes. Egg loss due to spill or other reasons at spawn time is documented. When eggs are shocked, unfertilized (dead) eggs are hand-counted and remaining eggs are machine counted. Due to error associated with machine counts, average fecundity is calculated using spawn-time egg sample data (see discussion above under CESRF Spawning and Survival) and adding in documented egg loss for all females divided by the number of females $(\mathrm{N})$ in the sample.

Table 35. Mean fecundity by age of adult females (BKD rank < 6) spawned at CESRF, 1997-present.

1. Given their length and fecundity, these fish may have been incorrectly aged.

## Juvenile Salmon Evaluation

## Food Conversion Efficiency

At the end of each month that fish are in the rearing ponds at the CESRF or the acclimation sites, a sample of fish are weighed and measured to estimate growth. These data, in addition to monthly mortality and pond feed data are entered into the juvenile growth and survival tracking database. Hatchery managers monitor food conversion (total pounds fed during a month divided by the total pounds gained by the fish) to track how well fish are converting feed into body mass and to evaluate the amount of feed that needs to be provided on a monthly basis. Average monthly food conversion and growth statistics for the CESRF facilities by brood year are provided in the following tables and figures.

Table 36. Mean food conversion (lbs fed/lbs gained) of CESRF juveniles by brood year and growth month, 1997 - present.

| Brood <br> Year | Apr | May | Jun | Jul | Aug | Sep | Oct | Nov | Dec | Jan | Feb | Mar |

## Length and Weight Growth Profiles

Figure 5. Mean fork length (cm) of CESRF juveniles by brood year and growth month, 1997-present.

Figure 6. Mean Weight (fish/lb) of CESRF juveniles by brood year and growth month, 1997 - present.

## Juvenile Fish Health Profile

Approximately 50-100 juveniles were sacrificed for juvenile fish health samples in the spring (usually in March) of their release year. Tissue samples from these fish were processed at USFWS laboratories in Olympia, Washington for presence of bacterial kidney disease (BKD) using enzyme-linked immunosorbent assay (ELISA) tests (see Female BKD Profiles and Appendix B for additional discussion). Fish were ranked high, moderate, or low (risk) based on the relative amounts of BKD in the tissue samples of the tested fish. These relative risk levels assume a good fish culture and rearing environment (i.e., water temperature and flows, nutrition, densities, etc. all must be conducive to good fish health). As indicated in Figure 7, juvenile fish released from the CESRF are largely in the low risk category for all brood years sampled to date. Due to budget issues and the low incidence observed over twenty years of testing, the USFWS discontinued testing of juveniles beginning with brood year 2017.

Figure 7. ELISA-risk profile of CESRF juveniles by brood year, 1997 - present (data source: USFWS).

## CESRF Spring Chinook juveniles released from Acclimation Sites (ELISA summary by Brood Year)

## Incidence of Precocialism

For brood years 2002-2004, the YKFP tested two different feeding regimes to determine whether a slowed-growth regime reduces the incidence of precocialism without a reduction in postrelease survival. The two growth regimes tested were a normal (High) growth regime resulting in fish which were about 30/pound at release and a slowed growth regime (Low) resulting in fish which were about 45/pound at release. As a critical part of this study, a team from NOAA Fisheries conducted research to characterize the physiology and development of wild and hatchery-reared spring Chinook salmon in the Yakima River Basin. While precocious male maturation is a normal life-history strategy, the hatchery environment may be potentiating this developmental pathway beyond natural levels resulting in potential loss of anadromous adults, skewing of sex ratios, and negative genetic and ecological impacts on wild populations. Previous studies have indicated that age of maturation is significantly influenced by endogenous energy stores and growth rate at specific times of the year. These studies will help direct rearing strategies at the CESRF to allow production of hatchery fish with physiological and life-history attributes that are more similar to their wild cohorts.

## CESRF Smolt Releases

The number of release groups and total number of fish released diverged from facility goals in some years. In brood year 1997, the Jack Creek acclimation facility was not yet complete and project policy and technical teams purposely decided to under-collect brood stock to allow a methodical testing of the new facility's operations with less risk to live fish, which resulted in the stocking of only 10 of the 18 raceways. In brood year 1998, the project did not meet facility release goals due to a biological specification that no more than $50 \%$ of returning wild fish be taken for brood stock. As a result only 16 raceways were stocked with progeny of the 1998 brood. In the same year, raceway 4 at the Jack Creek acclimation site suffered mechanical failures causing loss of flow and reduced oxygen levels and resulted in the loss of approximately one-half the fish in this raceway prior to release. In the drought year of 2001, a large number of returning adults presented with high enzyme-linked immunosorbent assay (ELISA) levels of Renibacterium salmoninarum, the causative agent of bacterial kidney disease (BKD). The progeny of these females were purposely destroyed. As a result, only nine raceways were stocked with fish. The project decided to use the fish from an odd raceway for a predator avoidance training sub-experiment (these fish were subsequently acclimated and released from the Easton acclimation site).

1. Brood years 1997-2001: Optimum Conventional Treatment (OCT). Brood Years 2002-2004: Normal (High) growth. Brood Years 2005-2012: Normal feed at Cle Elum or accl. sites.
2. Brood years 1997-2001: Semi-natural Treatment (SNT). Brood Years 2002-2004: Slowed (Low) growth. Brood Year 2005, 2007-2012: saltwater transition feed at accl. Sites; BY2014-present: BioPRO vs BioVIT diet. Brood Year 2006: EWS diet at CESRF through May 3, 2007.
3. At the Jack Creek acclimation site only 4 of 6 raceways were stocked, and raceway 4 suffered mechanical failures resulting in the loss of about 20,000 OCT (control) fish.
4. High BKD incidence in adult broodstock reduced production to just 9 ponds (Clark Flat 1-2, Jack Creek, and Easton). Easton ponds were used for predator avoidance trained (PAT) fish and a single Cle Elum pond was spread between 6 ponds at Easton with crowders used to simulate pond densities for fish at other acclimation sites. These releases were excluded from mean pond density calculations by treatment.
5. At the Jack Creek acclimation site raceway 3 suffered mechanical failures resulting in the loss of about 45,000 high-growth (control) fish.

Mean length and weight at release by brood year are shown in Figures 5 and 6 under Juvenile Salmon Evaluation, length and weight growth profiles. Mark information and volitional release dates are given in Appendix A.

## Smolt Outmigration Timing

The Chandler Juvenile Monitoring Facility (CJMF) located on the fish bypass facility of Chandler Canal at Prosser Dam (Rkm 75.6; Figure 1) serves as the cornerstone facility for estimating smolt production in the Yakima Basin for several species and stocks of salmonids.

Daily species counts in the livebox at the CJMF are expanded by the canal entrainment, canal survival, and sub-sampling rates in order to estimate daily passage at Prosser Dam (Pandit 2020). Expansion techniques for deriving Chandler smolt passage estimates are continually being reviewed and revised to incorporate new information. A subset of fish passing through the CJMF is sampled for presence of internal (CWT or PIT) or external (fin-clip) marks. All fish with marks are assumed to be of hatchery origin; otherwise, fish are presumed to be of natural origin.

Figure 8. Mean flow approaching Prosser Dam versus mean estimated smolt passage at Prosser of aggregate wild/natural and CESRF spring Chinook for outmigration years 1999-2020.

## Smolt-to-Smolt Survival

OCT-SNT Treatment (Brood Years 1997-2001, Migration Years 1999-2003)
Results of this experiment have been published:
Fast, D. E., D. Neeley, D.T. Lind, M. V. Johnston, C.R. Strom, W. J. Bosch, C. M. Knudsen, S. L. Schroder, and B.D. Watson. 2008. Survival Comparison of Spring Chinook Salmon Reared in a Production Hatchery under Optimum Conventional and Seminatural Conditions. Transactions of the American Fisheries Society 137:1507-1518.

Abstract - We found insufficient evidence to conclude that seminatural treatment (SNT; i.e., rearing in camouflage-painted raceways with surface and underwater structures and underwater feeders) of juvenile Chinook salmon Oncorhynchus tshawytscha resulted in higher survival
indices than did optimum conventional treatment (OCT; i.e., rearing in concrete raceways with surface feeding) for the specific treatments and environmental conditions tested. We reared spring Chinook salmon from fry to smolt in paired raceways under the SNT and OCT rearing treatments for five consecutive years. For four to nine SNT and OCT raceway pairs annually, we used passive integrated transponder, coded wire, and visual implant elastomer tags to compare survival indices for juvenile fish from release at three different acclimation sites 340-400 km downstream to passage at McNary Dam on the Columbia River, and for adults from release to adult return to Roza Dam in the upper Yakima basin. The observed differences in juvenile and adult survival between the SNT and OCT fish were either statistically insignificant, conflicting in their statistical significance, or explained by significant differences in the presence of the causative agents of bacterial kidney disease in juvenile fish at release.

High-Low Growth Treatment (Brood Years 2002-04, Migration Years 2004-2006)
Two early-rearing nutritional regimes were tested using hatchery-reared Yakima Upper spring Chinook for brood years 2002 through 2004. A low nutrition-feeding rate (low treatment or low) was administered at the Cle Elum Hatchery through early rearing to determine whether that treatment would reduce the proportion of precocials produced compared to a conventional feeding rate during early rearing. The conventional feeding rate, which served as a control treatment, is referred to here as a high nutrition-feeding rate (high treatment or high). Feed was administered at a rate of 10 grams/fish for the low treatment and 15 grams/fish for the high treatment through mid-October, after which sufficient feed was administered to both sets of treated fish to meet their feeding demands. The treatments were allocated within pairs of raceways (blocks), there being a total of nine pairs. The Low nutritional feed (Low) had a significantly lower release-to-McNary survival than did the High nutritional feed (High), respective survivals being $18.1 \%$ and $21.2 \%$ ( P < 0.0001 ; D. Neeley, Appendix B of 2008 annual report). The Low survival to McNary was consistently lower than the High at all sites in all years. Low-treated fish were smaller fish at the time of release and had somewhat later McNary passage times than high-treated fish. See also:

Feed Treatments (Brood Years 2005, 2007- 2010; Migration Years 2007, 2009-2018)
Prior to releases in 2007, and 2009-2018, two feed treatments were allocated to raceways within adjacent raceway pairs. The feeds tested included Bio-Oregon's BioPro, BioVita, and BioTransfer diets (see https://www.bio-oregon.com/). The intent of the experiments was to determine whether any of the various feeds conferred any life-stage survival advantages. Preliminary analyses indicated no significant or substantial differences between the feeds when
 annual report for additional detail.

## Control (Bio-Oregon) versus EWOS Feed Comparison (Brood Year 2006, Migration Year 2008)

This experimental design was similar to that for other studies described above with standard BioOregon pellets fed to half of the rearing ponds and an EWOS (https://www.cargill.com/animalnutrition/brands/ewos) diet fed to the other ponds. The different feed treatments only lasted about 6 weeks from the time of initial ponding as we found substantially higher mortalities for fish receiving the EWOS feed. From May 7, 2007 until these fish were released in 2008 all fish in this study received the Bio-Oregon diet. For the parameters of interest, we found no significant or substantial differences between the two feeding treatments (Appendix B of $\underline{2008}$ annual report).

## Smolt-to-Adult Survival

Calculation of smolt-to-adult survival rates for Yakima River spring Chinook is complicated by the following factors:

1) Downstream of the confluence of the Yakima and Naches rivers the three populations of spring Chinook (Upper Yakima, Naches, and American) are aggregated. A subsample of the aggregate wild/natural populations is PIT-tagged as part of the Chandler juvenile sampling operation but their origin is not known at the time of tagging. Through 2003, the primary purpose of this subsampling effort was to derive entrainment and canal survival estimates (see 2 below). Due to issues such as tag retention and population representation, adult detections of smolts PIT-tagged at Chandler cannot be used in any valid smolt-to-adult survival analyses.
2) Smolt accounting at Prosser is based on statistical expansion of Chandler smolt trap sampling data using available flow data and estimated Chandler entrainment rates. Chandler smolt passage estimates are prepared primarily for the purpose of comparing relative wild versus CESRF passage estimates and not for making survival comparisons. While these Chandler smolt passage estimates represent the best available data, there may be a relatively high degree of error associated with these estimates due to inherent complexities, assumptions, and uncertainties in the statistical expansion process. Therefore, these estimates are subject to revision. We are continuing to develop methods to subdivide the wild/natural outmigration into Upper Yakima, Naches, and American components based on DNA samples of juveniles taken at Chandler since 1998.
3) Installation of adult PIT detection equipment at all three ladders at Prosser Dam was not completed until the fall of 2005. Therefore, detection of upstream-migrating PIT-tagged adult spring Chinook at Prosser Dam was not possible for all returning fish until the spring of 2006. Periods of high flow may preclude use of automated detection gear so $100 \%$ detection of upstream migrants is not possible in all years.
4) Through 2006, detection of upstream-migrating PIT-tagged adult spring Chinook at Roza Dam occurred at an approximate $100 \%$ rate only for marked CESRF fish and wild/natural
fish taken for broodstock. The majority of wild/natural fish were passed directly back to the river without PIT interrogation.
5) For the 1997 brood (1999 out-migration), 400 Khz PIT-tags were used. Mainstem detection facilities were not configured to detect these tags at nearly the efficiency that they can detect the newer 134.2 kHz ISO tags. Although all marked adult fish are trapped and hand-wanded for PIT detections of adults at Roza Dam, the reliability of the 400 kHz detection gear and problems with hand-sampling in general likely precluded a complete accounting of all 1997 brood PIT returns.
6) All CESRF fish are adipose-fin clipped and subjected to higher harvest rates than unmarked wild/natural fish in marine and Columbia River mark-selective fisheries. No adjustments have yet been made in the following tables to account for differential harvest rates in these mark-selective fisheries.
7) PIT tag retention is a factor in estimating survival rates (Knudsen et al. 2009). No attempt has been made to correct the data in the following tables for estimates of tag retention.
8) The ISAB has indicated that "more attention should be given to the apparent documentation that PIT-tagged fish do not survive as well as untagged fish. This point has major implications for all uses of PIT-tagged fish as surrogates for untagged fish." Our data appear to corroborate this point (Tables 44-45). However, these data are not corrected for tag loss. If a fish loses its PIT tag after detection upon leaving the acclimation site, but before it returns as an adult to Roza Dam, it would be included only as a release in Table 45 and only as an adult return in Table 46. Knudsen et al. (2009) found that smolt-to-adult return rates (SARS) based on observed PIT tag recoveries were significantly underestimated by an average of $25 \%$ and that after correcting for tag loss, SARS of PIT-tagged fish were still $10 \%$ lower than SARS of non-PIT-tagged fish. Thus, the data in Table 45 under-represent "true" SARS for PIT-tagged fish and SARS for PIT-tagged and non-PIT-tagged fish are likely closer than those reported in Tables 44 and 45.
9) Due to issues relating to water permitting, size required for tagging, and allowing sufficient time for acclimation, CESRF juveniles are not allowed to migrate until at least March 15 of their smolt year. However, juvenile sampling observations at Roza Dam indicate that a substantial number of wild/natural juveniles migrate downstream during the summer, fall, and winter months prior to their smolt outmigration year (Figure 7). Comparison of SAR data for non-contemporaneously migrating juveniles may be invalid (see Copeland et al. 2015).

Given these complicating factors, Tables 39-45 present available smolt-to-adult survival data for Yakima River CESRF and wild/natural spring Chinook. Unfortunately, true "apples-to-apples" comparisons of CESRF and wild/natural smolt-to-adult survival rates are not possible from these tables due to complexities noted above. The reader is cautioned to correct these data for, or acknowledge the factors noted above prior to any use of these data.

1. Mean flow (cfs) approaching Prosser Dam March 29-July 4 of juvenile migration year. No data available for migration year 1991. In high flow years (flows at or > 5000 cfs ) operation of the Chandler smolt sampling facility may be precluded during portions of the outmigration. Data courtesy of U.S. BOR hydromet.
2. Aggregate of Upper Yakima, Naches, and American wild/natural populations.
3. Estimated smolt-to-smolt (release from upper Yakima River acclimation sites to Chandler) survival for CESRF juveniles.
4. Includes combined age- 3 through age- 5 returns. CESRF adult returns and smolt-to-adult survival values are understated relative to wild/natural values since these figures are not adjusted for differential harvest rates in mark selective fisheries in marine and lower Columbia River fisheries.
5. Available data were not sufficient to estimate juvenile flow-entrainment and passage of wild/natural fish.
6. Data for most recent years are preliminary; return data do not include age-5 adult fish.

Appendix B. Yakima River / CESRF Spring Chinook Salmon - Yakama Nation Data Summary

Table 40. Estimated wild/natural smolt-to-adult return rates (SAR) based on adult detections of PIT tagged fish. Roza tagged smolts to Bonneville Dam adult returns. Footnotes follow Table 42.

|  | Wild/Natural smolts tagged at Roza |  |  |  |  |  |

| 2014 | 1,104 | 0 | 3 | 0 | 3 | $0.27 \%$ |
| 2015 | 1,783 | 2 | 2 | 0 | 4 | $0.22 \%$ |
| 2016 | 2,578 | 1 | 0 |  | 1 | $0.04 \%$ |
| 2017 | 2,238 | 2 |  |  |  |  |

1. CESRF adult returns and smolt-to-adult survival values are understated relative to wild/natural values since these figures are not adjusted for differential harvest rates in mark selective fisheries in marine and lower Columbia River fisheries.
2. The reliability of the 400 kHz detection gear precluded an accurate accounting of all 1997 brood PIT returns. Therefore, this is not a true SAR. It is presented for relative within-year comparison only and should NOT be compared to SARs for other years.

Table 42. Overall McNary Dam smolt to Bonneville Dam adult return rates (SAR) based on juvenile and adult detections of wild/natural Yakima R. spring Chinook PIT-tagged and released at Roza Dam (Table B. 74 in McCann et al. 2020).

| Juvenile migration year | Smolts arriving $\mathrm{MCN}^{\mathrm{A}}$ | MCN-to-BOA without Jacks |  |  | MCN-to-BOA with Jacks |  |  |

| 2017 | 672,960 | 376 |  |  |  |  |

1. These fish were adipose fin-clipped, coded-wire tagged, and (beginning with 4 of 16 ponds in 1998) elastomer eye tagged. This is the number of fish physically counted at tagging.
2. BY1997 used 400 kHz tags and Bonneville Dam was not fully configured for adult detection of this type of tag; therefore we saw more detections at Roza Dam where fish were manually wanded for adult PIT detections.
3. Includes HxH fish beginning with this brood year.

## Harvest Monitoring

## Yakima Basin Fisheries

For spring fisheries in the Yakima River Basin, both the WDFW and the Yakama Nation employ two technicians and one biologist to monitor and evaluate in-basin harvest in the respective sport and tribal fisheries. Harvest monitoring consists of on-the-water surveys to collect catch data and to record tag information (e.g., elastomer, CWT, etc.) where possible for adipose-clipped fish. Survey data are expanded for time, area, and effort using standard methods to derive estimates of total in-basin harvest by fishery type (sport and tribal) and catch type (CESRF or wild denoted by adipose presence/absence). Results are presented in Table 46.

## Columbia Basin Fisheries

Standard run reconstruction techniques are employed to derive estimates of harvest from the Columbia River mouth to the Yakima River mouth for spring Chinook. Data from databases maintained by the United States versus Oregon Technical Advisory Committee (TAC) are used to obtain harvest rate estimates downstream of the Yakima River for the aggregate Yakima River spring Chinook population and to estimate passage losses from Bonneville through McNary reservoirs. These data, combined with the Prosser Dam counts and estimated harvest below Prosser, are used to derive a Columbia River mouth run size estimate and Columbia River mainstem harvest estimate for Yakima spring Chinook. Results are presented in Table 47.

Table 46. Spring Chinook harvest in the Yakima River Basin, 1985-present.

| Year | Tribal |  | Non-Tribal |  | River Totals |  |  | Harvest Rate ${ }^{1}$ |

1. Harvest rate is the total Yakima Basin harvest as a percentage of the Yakima River mouth run size.
2. Includes estimate of post-release mortality of unmarked fish.

1. Preliminary.

## Marine Fisheries

Based on available CWT information, harvest managers have long assumed that Columbia River spring Chinook are not harvested in any abundance in marine fisheries as the timing of their ocean migration does not generally overlap either spatially or temporally with the occurrence of marine fisheries (TAC 1997). The Regional Mark Information System (RMIS) will be queried regularly for any CWT recoveries of CESRF releases in ocean or Columbia River mainstem fisheries. Table 48 gives the results of a query of the RMIS database run on Jan. 5, 2021 for CESRF spring Chinook CWTs released in brood years 1997-2015 and Figure 8 shows recovery locations for CWTs recovered in marine fisheries 2008-2012. Based on the information reported to RMIS to date, it is believed that marine harvest accounts for about $0-4 \%$ of the total harvest of Yakima Basin spring Chinook. The apparent increase for brood year 2013 may be attributable to a number of factors including: preliminary data or changes in fish distribution, ecological conditions, or sampling rates. CWT recovery data for brood year 2016 were considered too incomplete to report at this time.

Table 48. Marine and freshwater recoveries of CWTs from brood year 1997-2015 releases of spring Chinook from the CESRF as reported to the Regional Mark Information System (RMIS) Jan. 5, 2021.

| Brood | Observed CWT Recoveries |  | Expanded CWT Recoveries |  |  |  |
| :---: | ---: | ---: | ---: | ---: | ---: | ---: |
| Year | Marine | Fresh | Marine $\%$ | Marine | Fresh | Marine $\%$ |
| 1997 | 5 | 56 | $8.2 \%$ | 8 | 321 | $2.4 \%$ |
| 1998 | 2 | 53 | $3.6 \%$ | 2 | 228 | $0.9 \%$ |
| 1999 |  | 2 | $0.0 \%$ |  | 9 | $0.0 \%$ |
| 2000 |  | 14 | $0.0 \%$ |  | 34 | $0.0 \%$ |
| 2001 |  | 1 | $0.0 \%$ |  | 1 | $0.0 \%$ |
| 2002 |  | 7 | $0.0 \%$ |  | 36 | $0.0 \%$ |
| 2003 |  | 4 | $0.0 \%$ |  | 10 | $0.0 \%$ |
| 2004 | 2 | 154 | $1.3 \%$ | 15 | 526 | $2.8 \%$ |
| 2005 | 2 | 96 | $2.0 \%$ | 2 | 304 | $0.7 \%$ |
| 2006 | 14 | 328 | $4.1 \%$ | 16 | 1160 | $1.4 \%$ |
| 2007 | 8 | 145 | $5.2 \%$ | 13 | 1139 | $1.1 \%$ |
| 2008 | 5 | 245 | $2.0 \%$ | 7 | 1634 | $0.4 \%$ |
| 2009 | 4 | 91 | $4.2 \%$ | 7 | 588 | $1.2 \%$ |
| 2010 | 4 | 164 | $2.4 \%$ | 9 | 948 | $0.9 \%$ |
| 2011 | 5 | 186 | $2.6 \%$ | 5 | 1030 | $0.5 \%$ |
| 2012 | 4 | 73 | $5.2 \%$ | 2 | 273 | $0.7 \%$ |
| 2013 | 9 | 65 | $12.2 \%$ | 20 | 534 | $3.6 \%$ |
| 2014 | 4 | 71 | $5.3 \%$ | 8 | 533 | $1.5 \%$ |
| $2015^{1}$ | 2 | 23 | $8.0 \%$ | 2 | 49 | $3.9 \%$ |

1. Reporting of CWT recoveries to the RMIS database typically lags actual fisheries by one to two years. Therefore, CWT recovery data for brood year 2015 are considered preliminary or incomplete.

Figure 9. Marine recovery locations of coded-wire-tagged CESRF spring Chinook, recovery years 2008-2012.

${ }^{1} \mathrm{BIO}=$ BioVita (BioOregon Protein Inc.) or control diet; STF = salt-water transition diet at acclimation sites. All fish are progeny of wild/natural parents unless denoted as HH which designates the hatchery control line beginning with brood year 2002. "Avg BKD" denotes the average BKD ELISA ranking of the female parents whose progeny were in these ponds.
${ }^{2}$ The number of fish released is estimated as the total number of fish counted at marking less mortalities documented from mark to release.

${ }^{1} \mathrm{BIO}=$ BioVita (BioOregon Protein Inc.) or control diet; STF = salt-water transition diet at acclimation sites. All fish are progeny of wild/natural parents unless denoted as HC which designates the hatchery control line beginning with brood year 2002. "Avg BKD" denotes the average BKD ELISA ranking of the female parents whose progeny were in these ponds.
${ }^{2}$ The number of fish released is estimated as the total number of fish counted at marking less mortalities documented from mark to release.

Appendix A. Tag and Release Information by Cle Elum Pond Id, Brood Years 2006-2019.

## Executive Summary

Outmigrating smolts have been monitored since 1983 at the Chandler Diversion Canal in the Yakima River at Prosser, Washington. Chandler Juvenile Monitoring Facility (CJMF) improvements over the years have made it possible to count all species entering the juvenile bypass system each year from January into July, encompassing the entire juvenile outmigration period. Winter operations are made possible by the dual purpose of the canal, which supplies a hydroelectric plant as well as an irrigation district. The diversion is located downstream from all Spring Chinook, Summer Chinook, Coho and Steelhead spawning and juvenile rearing areas in the Yakima River Basin.

Numerous projects to restore and protect channel and riparian habitat, along with fish reintroduction programs, have been implemented in the Yakima Basin since the 1990s. The population status and trends for the different species in their freshwater life stages are important measures of management success, and the data collected at the facility have allowed us to answer several management questions that can help to improve these programs. This report provides estimates of 2020 outmigrating Spring (yearling) Chinook smolt populations (hatchery and wild) past Prosser Dam; its temporal (annual) trend from 1999 through 2020; and evaluation of whether the production and releases of hatchery smolts into the upper Yakima had an effect on the production of wild smolts and on the relative abundance of the three stock sources of wild smolts (Naches, American, and Upper Yakima rivers). This evaluation is part of an ongoing study that was initiated in 1999 with the first release of hatchery Spring Chinook smolts.

The entire bypass flow leaving the juvenile screens enters the counting facility but only a portion is manually counted. A timer gate on an hourly cycle directs bypass flow to a holding tank for a portion of each hour that can be adjusted as often as once per day to compensate for fluctuations in fish abundance so as to not overwhelm the capacity of the staff to tally those smolts by species and stock.

In 2020, the CJMF was in operation from January $15^{\text {th }}$ to July $8^{\text {th }}$, a total of 178 days, with occasional closures (4 days) due to high stream flows or adverse river conditions. There were three gate timing settings (TR) for fish sampling. Over the 178 operating/sampling days, the timer gate was set at a $33 \%$ sample rate ( 20 minutes per hour) for 144 days, $50 \%$ for 9 days, and $100 \%$ for 20 days.

Several statistical methods/approaches were applied for expanding the subsample data and analyzing them. Most of the methods described in this report were based on the methods described in previous years' annual reports. To address the objectives of the study, we answered the following research questions:

## 1. Which species and runs were captured during the 2020 sampling period and what were the relative abundances of each group?

During the 2020 sampling period, a total of 97,447 individuals (raw, unadjusted value) of 18 species and runs were captured in the sampling room (Table 2, Figure 5). Among salmonids, hatchery and wild Spring Chinook $(56,669)$ comprised more than $50 \%$ of the total count; and the
second highest count was Steelhead (4946). Total counts varied over time, with $5 \%$ of the total pre-March, $2 \%$ in March, $47 \%$ in April, $46 \%$ in May and $0.5 \%$ post-May.

## 2. What was the PIT-tag detection efficiency of the monitoring facility and did the efficiencies vary among the sampling periods (pre-March, March, April, May, Post-May)?

The overall PIT-tag detection rate at the CJMF in 2020 was $43.96 \pm 1.0 \%$, which was higher than in $2019(27.85 \pm 0.07 \%$, mean $\pm$ SE), but the rate varied through the season. The highest detection rates occurred in April and May as diversion rate increased with decreasing river flow.
3. How many wild and hatchery Spring Chinook smolts were estimated to pass Prosser Dam during 2020 and was there any temporal trend from the 1999 through 2020 juvenile migration years?

Wild (natural-origin) spring chinook can be separated genetically into three stocks: Upper Yakima, from the Yakima River and tributaries above the Naches River confluence; American River, a tributary of the Naches River; and Naches River, from the Naches River and tributaries exclusive of the American River. Only the Upper Yakima stock receives hatchery supplementation.

The estimated number of wild Spring Chinook smolts passing Prosser Dam during the 2020 migration period ranged from 115,300 to 201,313; whereas hatchery smolts ranged from 371,069 to 500,195 . The estimated total number of hatchery Spring Chinook smolts passing Prosser Dam during the 2020 sampling period was almost double that of wild Spring Chinook smolts. On average over outmigration years 2000-2020, 226,910 $\pm 25,682$ wild and $322,679 \pm 15,931$ hatchery Spring Chinook smolts passed Prosser Dam each year. The total number of wild outmigrating smolts as well as the upper Yakima component stock seemed to be decreasing over time, whereas the population of Upper Yakima hatchery smolts seemed to be increasing but none of these trends were statistically significant.
4. What proportions of wild Spring Chinook populations that outmigrated from Prosser were contributed by different stocks (Naches, American, Upper Yakima) in the Yakima Basin? Did the proportions of these stocks in the outmigrating smolt population vary by migration year?

About $61 \%$ of the total count of wild outmigrating Spring Chinook smolts was contributed by the Upper Yakima stock; while $28 \%$ and $11 \%$ of the total wild outmigration were contributed by the Naches and American river stocks, respectively. The rate of decline in the wild Upper Yakima stock averaged -2498/year, which was the highest of the three wild populations (Naches, American, Upper Yakima), but the estimated decline was not significant (Upper Yakima; $R^{2}=0.02, p=0.47$ ). The rate of decrease for Naches stock was $-394 / y e a r$, it was also not significant; however, only the American stock average reduction was significant (Slope=1087/year, $\mathrm{R}^{2}=0.228$, $\mathrm{p}=0.04$ ).
5. Did the production and release of hatchery smolts into the upper Yakima affect the production of wild smolts?

To evaluate whether the hatchery program affected wild production, we tested a hypothesis that the rate of decline of outmigration should be higher in Upper Yakima wild Spring Chinook, because only the Upper Yakima stock receives hatchery supplementation. We found that there was no significant negative linear trend in the relative proportions of the three stocks of outmigrating smolt populations with the outmigration year, indicating that there was no influence of hatchery supplementation on wild abundance as measured by outmigrating smolt abundance at Prosser in the lower Yakima River. If the proportion of wild Upper Yakima smolts would have decreased significantly over time, this could represent a hatchery effect, environmental effects, or a combination of the two.

## 6. What was the effect of river flow (daily as well as annual flow) on the number of outmigrating Spring Chinook smolts?

The annual juvenile passage estimate of wild and hatchery Spring Chinook at Prosser Dam tends to increase with average annual river flow for the outmigration period, but this relationship was significant only for Upper Yakima hatchery smolts. The results further showed that daily estimated outmigrating smolts increased when flow pulses occurred, whether due to natural runoff or reservoir releases made to facilitate outmigration.

## 1. Introduction

Conservation and management of culturally and economically important species rely on monitoring programs to provide accurate and robust estimates of population size. Numerous projects to restore and protect channel and riparian habitat have been implemented on the Yakima River in coordination with reintroduction/supplementation programs. Quantifying and understanding whether juvenile outmigration or Smolt-to-Adult-Return (SAR) are increased/decreased over time, or which stocks perform better, are fundamental questions in determining whether species management and production goals are being reached.

Outmigrating smolts have been monitored since 1983 at the Chandler Diversion Canal in the Yakima River at Prosser, Washington (Figures 2-4). The diversion canal is located downstream from all Spring Chinook, Summer Chinook, Coho and Steelhead spawning and juvenile rearing areas in the Yakima River Basin. Improvements at the Chandler Juvenile Monitoring Macility (CJMF) over the years have made it possible to count all species entering the juvenile bypass system each year from January into July, encompassing the entire juvenile (smolt) outmigration period. Winter operations are made possible by the dual purpose of the canal, which supplies a hydroelectric plant as well as an irrigation district. Chandler Diversion canal typically conveys 1000 cfs with a maximum of 1500 cfs over the course of a year. Water not used for irrigation is returned to the Yakima River eleven miles downstream at the Chandler Powerhouse. The Yakima River at Prosser is characterized by a high spring runoff peaking in March, and low summer flows reaching a minimum in August, but there is wide variation in this flow pattern and the timing of high and low flows from year to year.

At the CJMF, fish are counted from the portion of river flow that is diverted into the irrigation canal and then into the juvenile fish bypass system. The monitoring data collected at the facility over the 6-month outmigration period can be useful to determine the status and trends of different species and runs at the outmigrating smolt stage, identify potential life-cycle bottlenecks, and evaluate the effectiveness of ongoing reintroduction and habitat improvement actions on population dynamics. The number of smolts of different species that outmigrate from the river basin are influenced by the numbers and fecundity of spawners and by the conditions their progeny encounter before and during outmigration, including river water temperature and river flows. Yakima River flow is modified by storage and releases from five large reservoirs in YKFP Project Year 2020 M\&E Annual Report, Appendix C, Chandler Certification
the upper Yakima Basin, and by irrigation and hydropower withdrawals and return flow. Under various agreements, minimum flows below storage and diversion dams are maintained to sustain ecological processes during periods of low natural runoff. Snowmelt exacerbated by occasional rain-on-snow events causes considerable variation in the flow of unregulated tributaries and in the Yakima River itself from November through June. When irrigation demand exceeds this runoff during the fish outmigration period, unnatural delays and poor outmigration survival can result. Studies of the relationship of river flow and outmigration have shown that river flow pulses from natural events and reservoir releases can accelerate smolt movement downstream and enhance survival to the ocean. Relying entirely on annual outmigration totals may obscure the role of in-season flow fluctuations and the importance of flow pulses during this critical period.

The main objectives of the study were to estimate prior-year (2020) outmigrating smolt populations (hatchery and wild) of spring Chinook; assess its temporal trend from 1999 through 2020; determine whether the production and releases of hatchery smolts into the upper Yakima had an effect on the production of wild smolts and on the relative abundances of the three stock sources of wild smolts (Naches, American, and Upper Yakima rivers); evaluate whether outmigration is higher in years of high river flow; and within years, on days with greater flow. To address the objectives, we answered the following research questions:

- Which species and runs were captured during the 2020 sampling period and what were the relative abundances of each group?
- What was the PIT-tag detection efficiency of the monitoring facility, and did the efficiencies vary among the sampling periods (pre-March, March, April, May, Post-May) in 2020?
- How many wild and hatchery Spring Chinook smolts emigrated from Prosser during 2020 and was there any temporal trend from 1999 through the 2020 juvenile migration year?
- What proportions of wild Spring Chinook populations that outmigrated from Prosser were contributed by different stocks (Naches, American, Upper Yakima) in the Yakima Basin? Did the proportions of these stocks in the outmigrating smolt population vary by migration year?
- Did the production and release of hatchery smolts into the upper Yakima affect the production of wild smolts?
- What was the effect of river flow (daily as well as annual flow) on the number of outmigrating Spring Chinook smolts?

### 2.0 Methodology

The CJMF is located on the fish bypass outlet of Chandler Canal at Prosser Dam (Figure 1), which is about 76 river km ( 47 river miles) upstream from the mouth of the Yakima River. The canal supplies water for irrigation and to generate power. The Chandler Canal typically conveys 1000 cfs with a maximum of 1500 cfs over the course of a year (Pyper and Smith, 2005). The proportion of river flow diverted, and thus the proportion of smolts entrained, varies widely during the outmigration season, due mostly to fluctuations in river flow. Juvenile fish screens (Figure 2) allow fish to exit the canal. The bypass flow enters a juvenile counting facility before returning to the river, where a portion of the fish are manually counted. A timer gate on an hourly cycle directs bypass flow to a holding tank for a portion of each hour that can be adjusted as often as once per day to compensate for fluctuations in fish abundance and avoid overwhelming the capacity of the staff to tally those smolts by species and stock. For this study, several methods were used to enumerate smolts and are outlined in Figure 3.

Figure 1. Yakima basin and the location of the Chandler Juvenile Monitoring Facility at Prosser and different sub-basins or genetic stocks (Naches, Upper Yakima River and American River).

Figure 2. Composite photo depicting the Chandler canal location and the key sampling components at the Chandler Juvenile Monitoring Facility.

### 2.1. Estimating Sample Rate and Calibration

Figure 4 is a schematic of the CJMF layout and the details of the sampling area. The sampling period was continuous from January $15^{\text {th }}$ to July $8^{\text {th }}$ in 2020 except for a few days in which the facility was shut down due to adverse river conditions. In 2019, the sampling period was from January $9^{\text {th }}$ to July $6^{\text {th }}$.

Figure 3. Outline of the methodology used for data analysis in this report

In 2020, three timer-gate settings (TR) were used to control the proportion of bypassed smolts that were manually counted: $33 \%$ ( 20 minutes per hour), $50 \%$ ( 30 minutes per hour), and $100 \%$. There are two PIT-tag detectors in the bypass system (Figure 4): one upstream of the timer gate and one in the exit from the counting facility downstream of the timer gate where the daily subsamples of smolts are tallied. Along with detectors in the Prosser adult ladders, these detectors comprise site PRO in the PIT Tag Information System (PTAGIS) maintained by the Pacific States Marine Fisheries Commission.

Figure 4. Site Overview of Chandler Juvenile Monitoring Facility at Prosser. The layout was adapted from the site configuration at https://www.ptagis.org/.

The timer gate, when opened, directs the Prosser bypass flow from Chandler Canal into the sample tank where smolts are tallied. Data regarding species, life stage, and abundance were tallied and counted daily during the sampling period. The timer gate setting has to be corrected because some bypassed fish swim against the bypass flow and may not enter the counting facility in strict proportion to the gate setting. For a given daily TR setting, the observed sample rate was computed as:
$\mathrm{SR}_{\mathrm{ti}}: \frac{\text { the number of PIT-tagged Spring Chinook smolts detected leaving the counting facility }}{\text { the total number detected by the bypass detector located upstream of the timer gate }\left(T G_{i}\right)}$; or
$\mathrm{SR}_{\mathrm{t}} \mathrm{i}=\frac{\mathrm{n}[\text { counting facility }]}{\mathrm{n}[\text { bypass }(\mathrm{TR})]}$; Where $t i$ is the timer setting.

Once we estimated the daily sample rate, the calibration value was computed as:

Calibration value $(\mathrm{CV})=\mathrm{w}(33 \%) \times[\mathrm{SR}(\mathrm{TR}=33 \%) / 33 \%]+\mathrm{w}(50 \%) \times[\mathrm{SR}(\mathrm{TR}=50 \%) / 50 \%]$

Where $\mathrm{w}(33 \%)$ and $\mathrm{w}(50 \%)$ are the weight, which are the proportion of bypass detections within the TR setting 0.33 and 0.50 , respectively. The weights being the proportions of bypass detections within the TR setting and estimated as (see, Neeley 2012):

$$
\begin{aligned}
& \mathrm{w}(33) \%=\mathrm{n}[\operatorname{bypass}(\mathrm{TR}=33 \%)] /\{\mathrm{n}[\operatorname{bypass}(\mathrm{TR}=33 \%)]+\mathrm{n}[\operatorname{bypass}(\mathrm{TR}=50 \%)]\} \\
& \mathrm{w}(50) \%=\mathrm{n}[\operatorname{bypass}(\mathrm{TR}=50 \%)] /\{\mathrm{n}[\operatorname{bypass}(\mathrm{TR}=33 \%)]+\mathrm{n}[\operatorname{bypass}(\mathrm{TR}=50 \%)]\}
\end{aligned}
$$

### 2.2. Missing data imputation

Spring Chinook smolts were tallied each day as to source (hatchery-spawned or wild) on the basis of external marks. However, the sampling facility was shut down for a few days due to flow conditions or other technical problems. Data were missing for those days in which the sampling facility was closed. Linear interpolation was used to impute counts for days with missing information.

### 2.3. PIT-tag data

We queried the PTAGIS database (https://www.ptagis.org/) in April 2021 to retrieve available PIT-tag detection information for all tagged hatchery Spring Chinook smolts released upstream from Prosser Dam. Altogether 43,130 hatchery Spring Chinook were tagged, (about 6\% of the total release) but not all the tagged fish were detected at the acclimation site exits, either because of mortality and tag shedding over the 3-to-5-month period between tagging and volitional release, or detection failure on exit. We used only those fish which were detected on exit from acclimation sites or captured, tagged and released in the Roza Dam bypass in the upper Yakima River. A total of 35,522 PIT-tagged smolts were used for this analysis. An encounter history for each fish with detection events (date and detection site) was constructed for further analysis.

### 2.4. Genetic information

During the sampling period each year, tissue samples were taken from subsamples of wild smolts passing through the counting facility. In order to minimize bias, samples of smolts were distributed proportionally among five time strata (January-February, March, April, May and

June). These tissue samples were processed in the Molecular Genetics Laboratory of the Washington Department of Fish and Wildlife (WDFW). Results of 2019 and 2020 molecular samples are available (Seamons and Bowman, 2020) and these information was used to estimate 2019 and 2020 outmigrating smolts.

### 2.5. Estimating Prosser bypass detection rate

The proportions of all PIT- tagged smolts released above Prosser and detected at mid-Columbia dams that were previously detected in the Chandler Canal bypass serve as estimates of bypassdetection rate. Detections at the three downstream sites with juvenile PIT tag detection (McNary, John Day, and Bonneville dams) were pooled to estimate the Prosser bypass detection rate. Daily estimates of Prosser detection rate from downstream dams are not possible because smolts migrate at different rates between Prosser and downstream dams, and one day's detections in the Prosser bypass are detected at a given downstream dam over several subsequent days. For this study, the detection rate was estimated for five strata over the outmigration period (pre-March, March, April, May and post-May) based on McNary Dam alone, or pooled over the three Columbia River dams. The detection efficiency (DE) was estimated as:
$\mathrm{DE}=\mathrm{n}($ daily joint site detections $) / \mathrm{n}($ total site detections $)$

These detection rates based on upper Yakima hatchery Spring Chinook were also applied to the three stocks of wild Spring Chinook smolts, few of which were tagged. The wild Spring Chinook were made up of Naches, American, and Upper-Yakima stock (See fig. 1). All hatchery Spring Chinook smolts were coded-wire tagged and most were elastomer tagged in addition to about $6 \%$ being PIT-tagged. Elastomer tags allowed visual separation of hatchery smolts and adults by acclimation site, with fish released from the Clark Flat, Easton, and Jack Creek sites, receiving red, green, and orange elastomer tags, respectively. Elastomer-tagged smolts were also tallied by elastomer color. PIT-tagged hatchery smolts were not elastomer-tagged.

The wild and elastomer-tagged hatchery tallies were expanded by four different estimates of Prosser detection rates as mentioned above.

1. McNary-based un-stratified detection rate estimate
2. McNary-based stratified detection rate estimate
3. Pooled-lower-dam-based un-stratified detection rate estimate
4. Pooled-lower-dam-based stratified detection rate estimate

Detailed methodology is given in Neeley (2019).

Of these four estimators, the one chosen for further analysis was a pooling of stratified estimates from the detection efficiencies from McNary, John Day, and Bonneville Dams on the Columbia Rivers; the strata being established for each of these dams by combining daily estimates that were deemed similar using Logistic stepwise regression of the daily detection efficiencies on Julian-date indicators that take the value 1 if the estimate was from a given date or a later date or 0 if the estimate was from an earlier date ( see, Neeley (2019) for further details).

### 2.6. Wild and hatchery passage estimate

On a daily basis the sampled Spring Chinook smolts were tallied as to source (hatchery-spawned or wild). On those days when the facility was shut down, linear interpolation was used to impute values to the missing information as mentioned above. The daily actual and imputed tallies were divided by the sample rates in use on those days (SR). The sample-rate-adjusted tallies for each source were added over days within each of five time periods and were then divided by the respective period's detection rate. The wild and hatchery smolts were tallied separately. Wild smolts were identified by the lack of a coded-wire tag or external mark. Hatchery smolts could be identified by the presence of an elastomer tag, a coded wire tag, an adipose fin clip and a PIT tag if there was no elastomer tag. Expanded elastomer-tagged tallies were then divided by the proportion of hatchery smolts to obtain estimates of the passage of all hatchery smolts.

Within each of the five time periods (pre-March, March, April, May, post-May), the tallied sample of wild smolts was subsampled and genetically classified as to brood origin (American, Naches, or Upper Yakima rivers) by the Washington Department of Fish and Wildlife Molecular Genetics Laboratory so that brood-origin proportions could be estimated for each stratum. The wild passage estimates within each period were multiplied by each of the period's brood-source proportions. Each wild brood's time-period passage estimates were then added over the time
periods to estimate the brood's total passage, as were the hatchery passage estimates. The detailed methodology can be found in Neeley (2019).

### 2.7. Model validation (estimates comparisons)

The estimates of the number of smolts passing Prosser Dam can vary slightly with different entrainment-based estimation methods. To ascertain which of these passage estimates is the best to report and use for further analysis, we compared flow/entrainment-based estimates of hatchery Spring Chinook smolts at Prosser to another estimate that was derived using a PIT-tag-based survival rate from release site to Prosser Dam. Since we know the total number of hatchery Spring Chinook smolts released in the upper Yakima, we multiplied the survival rate by the total release, which provided the total hatchery smolt population passing Prosser. This estimate can be viewed as an independent estimate but it can also be biased because we assumed there was no variation in the survival rate among the sampling days time strata. If detection rate is not homogeneous, survival rate cannot be homogeneous. However, this survival-based estimator has value because it is independent of the flow/entrainment-based method.

In addition to the survival-based method, each of the flow/entrainment methods' estimates of hatchery juvenile passage (see section 2.5 above) was also compared with hatchery adult returns at Prosser (Bosch, 2020). If the estimate is a reasonable value, it should be highly correlated with the hatchery adult returns from that outmigration.

### 2.8. Estimated Daily smolt outmigration from Prosser

One of our objectives was to determine whether river flows influence the size of the population of outmigrating smolts If larger number of smolts outmigrated during high river flow, the rate of outmigration would be a function of river flow. To estimate daily passage at Prosser Dam, daily counts of each species in the live box at the (CJMF) were expanded by the canal entrainment, canal survival (from prior paired releases), and sub-sampling rates using the following formula (Neeley, 2012).

Entrainment rate $(E R)=1 / 1+\exp (-5.60081+13.5861 *$ diversion rate $) ..$ eq. 1
Survival Probability =
$1 / 1+\exp (-2.84815+0.0154 *$ Juliandate $-0.00017 *($ canalflow +132$) ..$ eq. 2

Estimated daily count: Count/(Survival Probability * sample. rate(SR) * ER) .. eq. 3

The model for the Entrainment Rate (ER) was based on the logistic regression using the daily proportion of Yakima River flow diverted into the canal. The Entrainment Rate (ER) is the predicted daily proportion of fish passing Prosser that are entrained into Chandler Canal, the Canal-Survival Rate (Survival probability) is the daily predicted proportion of those entrained fish that survive the canal from below the head-gate down the canal and into the bypass to a point just above the sampling station, and Sampling Rate (SR) is the estimated proportion of fish that are sampled from the bypass and enumerated.

### 2.8.1. Relationship between river flow and estimated daily count

To determine whether high river flow helped to increase the rate of smolt outmigration from Prosser, we built univariate relationships using two datasets (annual and daily).
A. Annual total estimates: A univariate linear relationship between the estimated total annual number of hatchery Spring Chinook smolts passing Prosser (2000-2020 outmigration years) and the average March-June river flows (corresponding to the March-June volitional exit of hatchery Spring Chinook from acclimation sites) for each year from 2000 through 2019.
B. Daily estimates: A univariate linear relationship between the estimated daily count of wild Spring Chinook and daily river flow above Prosser Dam, which is the sum of the daily flows measured at the Bureau of Reclamation gaging stations CHCW (Chandler Canal) and YRPW (Yakima River below Chandler Canal). River flow data were accessed in May, 2021 from
https://www.usbr.gov/pn/hydromet/yakima/yakwebarcread.html.

### 3.0 Results and discussion

In 2020 the CJMF was operated from January $15^{\text {th }}$ to July $8^{\text {th }}$ ( 178 days total), with occasional closures (4 days) due to excessively high stream flows or other technical problems. There were three timer gate settings (TR) for sampling, representing the percentage of time in each hourly cycle that bypassed fish were directed into the sample tank. Over the sampling period, the timer gate setting (TR) was $33 \%$ for 144 days, $50 \%$ for 9 days, and $100 \%$ for 20 days. As noted earlier, adjustments are applied to timer gate settings because some bypassed fish swim against the bypass flow upstream from the gate and may not enter the counting facility in strict proportion to the gate setting, unless there is no alternative, i.e. the gate is set to sample $100 \%$ of bypass flow. This occurs at the end of the season when lethal lower river conditions require transportation of entrained smolts to the Columbia River instead of discharge past the sample room detector to the Yakima River.

The SR is usually less than the TR, indicating not all fish passing through the bypass when the timer gate is open are actually entering and being detected in the counting facility. In 2020, when TR was $33 \%$, sample rate (SR) was $26.1 \%$, and at the $50 \%$ TR setting the SR was $39.7 \%$ (Table 1). The 2020 sample rate was lower than the rate in 2019 and 2018 but similar to the rates in 2017, 2009, 2007, 2000 and 1992 (Table 1). Why there was variation in sampling rate among years is a topic for further investigation, with potential causes including water temperature, fish size or other factors.

Table 1. Sample-room sample rates for given timer-gate settings. Timer Gate Rate (TR) is the proportion of time that the bypass gate is opened to Sample Room.

### 3.1. Species composition and daily counts in the counting facility

During the 2020 sampling period, a total of 97,447 individuals (raw, unadjusted value) of 18 species and runs were captured in the sampling room (Table 2, Figure 5). Among salmonids, hatchery and wild Spring Chinook $(56,669)$ comprised more than $50 \%$ of the total count; and the second highest count was Steelhead $(4,946)$. Total counts varied over time, with $5 \%$ of the total pre-March, $2 \%$ in March, $47 \%$ in April, $46 \%$ in May and $0.5 \%$ post-May.

Table 2. Total counts by species in the Sample-room sample rates for 2019 and 2020.

| Species | 2019 | 2020 |
| :--- | ---: | ---: |
| Bass | 84 | 87 |
| Bigmouth Minnow | 187 | 131 |
| Bluegill | 68 | 113 |
| Carp | 22 | 176 |
| Catfish | 809 | 757 |
| Chiselmouth | 2393 | 280 |
| Crappie | 19 | 47 |
| Dace | 3 | 0 |
| Lamprey | 3654 | 138 |
| Hatchery Spring Chinook | 29532 | 39047 |
| Perch | 17 | 24 |
| Pumpkinseed | 1 | 0 |
| Shiner | 33 | 11 |
| Sockeye | 32 | 5593 |
| Sucker | 1079 | 590 |
| Whitefish | 357 | 215 |
| Summer/Fall Chinook | 13411 | 26497 |
| Wild Spring Chinook | 13507 | 14925 |
| Coho | 8075 | 1850 |
| Wild Steelhead | 5440 | 4946 |

Figure 5: Daily catch (raw count) of different species from January through July 2019 (sampling period). Number in green color is the total counts in the sampled during the sampling period.

### 3.2. Counts of wild and hatchery Spring Chinook

Daily raw counts of the of the hatchery and wild Spring Chinook were divided by the daily sampling rate to arrive at the total number bypassed each sampling day. Missing counts were estimated by linear interpolation for those days in which no sampling was done as mentioned in methodology. After the adjustments, total counts of bypassed hatchery and wild spring Chinook during the sampling period in the sampling facility were estimated to be 148,967 and 53,095 , respectively (Table 3). Wild Spring Chinook passed Prosser Dam earlier than their hatchery counterparts, starting with the January initiation of sampling, while hatchery Spring Chinook were not observed until after their volitional release from acclimation sites began in mid-March. The outmigration of both groups was nearly complete by the end of May and ending in late June. The wild counts peaked in April and the hatchery counts peaked in May when fish remaining in acclimation sites were forced out (Table 3, Figure 6).

Table 3 and Figure 6 also contain 2019 counts to illustrate some of the annual variability in Spring Chinook outmigration timing. In 2019 the pre-March and May periods had higher bypass counts of wild fish than April, while hatchery counts were somewhat later in 2019 than in 2020. Annual fluctuations in outmigration timing are a subject for further investigation.

Table 3. Adjusted total count (raw count $x$ sample rate (SR)) of bypassed hatchery and wild Spring Chinook smolts in the Chandler Juvenile Monitoring Facility over 5 temporal strata in 2019 and 2020.

|  |  | Counts (adjusted) |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Migration <br> year | Origin | Pre-March | March | April | May | Post-May | Total |
|  | Wild | 15,489 | 3,937 | 10,596 | 23,290 | 63 | 53,374 |
| 2019 | Hatchery | 0 | 904 | 24,775 | 76,824 | 198 | 102,701 |
|  | Wild | 8,843 | 2,602 | 30,737 | 10,851 | 58 | 53,092 |
| 2020 | Hatchery | 8 | 1,419 | 64,446 | 82,305 | 789 | 148,967 |

Figure 7. Cumulative catch proportion of bypassed wild and hatchery Spring Chinook by date for 2019 and 2020

### 3.3. Detection rate of the sampling facility and downstream Dams (MCJ, John Day, BON)

A total of 9519 PIT-tagged hatchery Spring Chinook were detected at the CJMF in 2020. The number of tagged fish detected at Prosser that were also detected at downstream dams depended on downstream detection probability in addition to downstream mortality. Joint detections of hatchery Spring Chinook between Prosser (PRO) and McNary (MCJ), PRO and John Day (JDJ); and PRO and Bonneville Dam (B2J/BCC) in 2020 were found to be 240, 402, and 644, respectively ( 1286 total). In 2019, joint detections were lower for all dams except at PRO-MCJ: 369, 320, and 465, (1154 total), for PRO-MCJ, PRO-JDJ and PRO-BON, respectively (Table 4).

Overall detection rate at Prosser in 2020 (pooled $43.96 \pm 1.0$ \%) was higher than in $2019(27.85$ $\pm 0.07 \%)$. The higher detection rate in 2020 was true regardless of which downstream dam was used for a reference to evaluate the Prosser detection rate (Table 4). The most obvious reason for fluctuations in detection rates is fluctuations in diversion rates, but the mean diversion rate for the hatchery spring chinook outmigration period in both years was similar. The timing differences within the outmigration period that were discussed earlier, and their interaction with irrigation demand and river flow could result in an effect on detection rate not evident from a simple mean of diversion rate over the entire outmigration period, or other factors could be responsible. The joint detection rate also varied by stratum or time window (before March, March, April, May and after May) for the tagged hatchery Spring Chinook. Because volitional exit began March 15 in 2020, Prosser detections of hatchery smolts are not expected until late March. Therefore, there were no detections pre-March, and the most detections were in April and May (Table 5). The highest detection rate was in May; whereas the lowest was pre-March the smolts in both years (2019 and 2020) regardless whether it was based on the MCJ reference or all downstream detection sites pooled together (MCJ, JDJ and B2J/BCC, Table 4). This may be related at least in part to normal within-season variations in river flow and diversion quantity.

Table 4. Detection efficiencies of Prosser (PRO) and joint detection of hatchery Spring Chinook smolts between PRO and McNary (MCJ), PRO and John Day (JDJ), PRO and Bonneville (B2J/BCC); and PRO and the pooled detections at MCJ and downstream sites. Detection at Bonneville included the juvenile (smolt) population of hatchery Spring Chinook detected by B2J at BCC antennas, which cover different passage routes. The pooled (ALL) estimate represents the detection probability at Prosser based on detection at one or more downstream dams (MCJ, JDJ and BON).

| Migrationyear | Joint Detection at PRO with | Months |  |  |  |  | Total | Rate of Detection at Prosser (\%) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Pre- <br> March | March | April | May | PostMay |  |  |
| 2019 | McNary (MCJ) | 0 | 6 | 143 | 220 | 0 | 369 | $27.09 \pm 1.2$ |
|  | John Day (JDJ) | 0 | 2 | 94 | 224 | 0 | 320 | $29.46 \pm 1.4$ |
|  | Bonneville (BON) | 0 | 4 | 174 | 287 | 0 | 465 | $27.04 \pm 1.8$ |
|  | Pooled (All) | 0 | 12 | 411 | 731 | 0 | 1154 | $27.85 \pm 0.7$ |
| 2020 | McNary (MCJ) | 0 | 7 | 117 | 116 | 0 | 240 | $33.44 \pm 1.8$ |
|  | John Day (JDJ) | 0 | 4 | 146 | 252 | 1 | 402 | $46.20 \pm 1.8$ |
|  | Bonneville (BON) | 0 | 5 | 295 | 342 | 2 | 644 | $46.66 \pm 1.4$ |
|  | Pooled (All) | 0 | 16 | 558 | 710 | 3 | 1286 | $43.96 \pm 1.0$ |

Table 5. Detection rate of hatchery Spring Chinook smolts at Prosser Dam based on strata (Unstratified and Stratified) with the reference of McNary Dam and pooled over the three Columbia River dams (MCJ, JDJ and B2J/BCC) for 2019 and 2020. The redistributed detection rate was estimated by pooling the five time periods into two groups: pre-March through April, and May through Post-May.

| Migration <br> Year | Reference | Stratified / unstratified | Pre- <br> March | March | April | May | Post- <br> May |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 2019 | Based on McNary Dam | Un-stratified | 27.61\% | 27.61\% | 27.61\% | 27.61\% | 27.61\% |
|  |  | Stratified | 0.00\% | 19.38\% | 17.72\% | 39.63\% | 0.00\% |
|  |  | Stratified (Redistributed) | 18.47\% | 18.47\% | 18.47\% | 39.63\% | 39.63\% |
|  | Based on pooled Dams (McJ, JDJ and BON) | Un-stratified | 27.93\% | 27.93\% | 27.93\% | 27.93\% | 27.93\% |
|  |  | Stratified | 0.00\% | 24.64\% | 20.27\% | 36.13\% | 0.00\% |
|  |  | Stratified (Redistributed) | 20.07\% | 20.07\% | 20.06\% | 35.88\% | 35.88\% |
| 2020 | Based on <br> McNary Dam | Un-stratified | 33.44\% | 33.44\% | 33.44\% | 33.44\% | 33.44\% |
|  |  | Stratified | 0.00\% | 11.85\% | 22.72\% | 57.96\% | 0.00\% |
|  |  | Stratified (Redistributed) | 23.68\% | 23.68\% | 23.68\% | 57.96\% | 57.96\% |
|  | Based on pooled Dams (MCJ, JDJ and BON) | Un-stratified | 43.96\% | 43.96\% | 43.96\% | 43.96\% | 43.96\% |
|  |  | Stratified | 0.00\% | 14.87\% | 33.21\% | 59.30\% | 24.56\% |
|  |  | Stratified (Redistributed) | 32.26\% | 32.26\% | 33.30\% | 59.23\% | 59.23\% |

### 3.4. Predicted number of outmigrating wild and hatchery Spring Chinook smolts

The total number of hatchery Spring Chinook smolts passing Prosser Dam during the 2019 and 2020 migration periods was almost double that of the wild (natural-origin) run (Table 6). Furthermore, outmigrating smolts of hatchery origin were more numerous in 2020 than in the 2019 outmigration period by all of the four estimation methods employed. Applying the detection rates derived from hatchery Spring Chinook to their wild counterparts (Table 5), the estimates of wild Spring Chinook smolts passing Prosser Dam also varied between years. Depending on the estimation method, wild outmigration ranged from 154,530 to 175,427 in 2019; and from 115,300 to 201,313 in 2020. The hatchery smolt estimates ranged from 310,836 to 353,803 in 2019 and from 371,069 to 500,195 in 2020.

The details of the juvenile Spring Chinook passage estimates at Prosser Dam based on different estimators from 1999-2020 are given in Appendix A of this report. The estimates based on the method with temporal strata Pre-May, May, June, Post-June was found to be slightly higher than the estimates based on non-stratified detection rates.

Table 6. The estimated number of wild and hatchery Spring Chinook smolts migrating past Prosser Dam in 2019 and 2020 using four estimation methods.

| Migration Year | Origin | Estimates of outmigration population based on different methods |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | McN_UnStr (Method1) | $\begin{gathered} \text { McN_Str } \\ \text { (Method 2) } \end{gathered}$ | Pooled_UnStr <br> (Method 3) | Pooled_Str (Method 4) |
| 2019 | Natural Origin | 168,119 | 154,848 | 175,427 | 154,530 |
|  | Hatchery | 310,836 | 353,803 | 319,579 | 343,212 |
| 2020 | Natural Origin | 201,313 | 168,133 | 151,265 | 115,300 |
|  | Hatchery | 456,852 | 500,195 | 371,069 | 380,494 |

Choosing the best estimate was challenging. We compared these estimates with another independent estimate derived from survival rate (Table 7). In migration year 2020, the average survival rate from the three acclimation sites to Prosser Dam was $71.22 \pm 3.91 \%$ (based on the CJS model) and the total number of released hatchery Spring Chinook smolts during 2020 was 624,200. Multiplying the survival rate by the released population, the total outmigration of hatchery Spring Chinook from Prosser was estimated to be 444,555 $\pm 47,958$ (mean $\pm 95 \%$ confidence Intervals). This estimate was closest to the estimate derived from the pooled stratified (redistributed) method (Tables 6 and 7).

Table 7. Number of Spring Chinook (hatchery) smolts release at Acclimation sites and its survival rate from the acclimation sites to Below Prosser based on CJS model and the estimated outmigration smolts from Prosser Dam for the migration year 2019 and 2020.

| Migration Year | No. of smolts at Acclimation sites | Survival rate from the acclimation site to below Prosser |  | Estimated outmigration smolt from Prosser |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Average | SE | Average | 95\% CI |
| 2019 | 673,218 | 50.82 | 2.2 | 342,129 | 29,103 |
| 2020 | 624,200 | 61.22 | 3.91 | 382,135 | 47,958 |

However, the estimates based on survival rate may still have some bias because the survival rate may not be homogeneous among the sampling months, especially due to variation in river flow at Prosser within the sampling period. However, previous years' analyses also showed that the estimate based on pooled-lower-dam-based stratified detection rate (method 4) was highly correlated with hatchery returns.

### 3.5. Annual trend of juvenile Prosser-passage estimates (hatchery and wild) by stock

Annual juvenile Prosser-passage estimates from outmigration years 1999 through 2020 are given in Table 8 by stock of wild/Natural origin (Naches, American, and Upper Yakima rivers) plus hatchery Upper Yakima River origin. It showed that Prosser juvenile estimates for both wild (natural) and hatchery vary among the outmigration year. Total Spring Chinook outmigration per year was $551,589 \pm 29,107$. However, in an average year, $226,910 \pm 25,682$ wild and $324,679 \pm$ 15,931 hatchery Spring Chinook smolt passed downstream at Prosser (Table 8 and Figure 8). Wild (natural) Spring Chinook from the American River had the lowest average, Naches had the second, and the supplemented Upper Yakima stock had the highest average among the wild stocks (Figure 8). Hatchery juvenile Spring Chinook passage at Prosser Dam in 2020 was the highest since 2014 (Table 8).

Table 8. Annual estimated wild and hatchery-origin smolt passage at Prosser Dam from 1999 through 2020. Estimates for the outmigration years from 1998 through 2018 were adopted from Neeley (2019).

| Brood Year (BY) | Outmigrat ion Year | Wild Stock Estimates |  |  |  | Hatchery <br> (Upper <br> Yakima) | Total Wild \& Hatchery |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Total Wild | Naches | American | Upper <br> Yakima |  |  |
| 1997 | 1999 | 584,016 | 93,427 | 63,000 | 427,588 | 187,669 | 771,685 |

| Average/year |  | 226,910 | 59,894 | 24,536 | 146,728 | 324,679 | 551,589 |
| Standard Error (SE) |  | 25,682 | 5,348 | 3,266 | 21,313 | 15,931 | 29,107 |

Figure 8. Average annual Prosser-passage estimates for wild and hatchery Spring Chinook by stock, outmigration years 2000-2020. The dot within each box is the mean and the horizontal line is the median. Outmigration year 1999 was not included for this box plot because in that year only a few raceways were used for hatchery production, and 1999 was also the last outmigration year in which "ISO" PIT tags with poor read range were used.

Because the smolt passage estimates for the three largest stock groupings (Total wild, Upper Yakima wild, and Upper Yakima hatchery) varied by outmigration year, we further estimated whether the outmigration smolt decreased over years (temporal trends) and whether there were differences among stocks. In 1999, only 14 of 18 raceways were used for hatchery production. As a result, the Prosser passage estimates for hatchery smolts in 1999 were low, which might not compare well with other years' hatchery estimates. Two relationships were developed using the data with and without 1999's passage estimates for all three groups (total wild, Upper Yakima wild, and Upper Yakima hatchery). In both datasets, the total number of outmigrating wild smolts and the number of wild upper Yakima smolts seemed to be decreasing over time, whereas the population of hatchery in Upper Yakima sub-basin seemed to be increasing; but neither trend was statistically significant (Figure 9).

Figure 9. Estimated passage at Prosser Dam for total wild, Upper Yakima wild, and Upper Yakima hatchery Spring Chinook smolts with predicted trends by outmigration year. A1, B1 and C1 are for outmigration years 2000-2020 (omitting 1999 data); whereas the A2, B2 and C2 relationships were developed using all outmigration years from 1999 through 2020.

Although outmigration of hatchery smolts is increasing but not significantly, there is a possibility that a true positive increase in hatchery smolts coming from the Upper Yakima would have an associated true negative decrease in Upper Yakima wild passage. Therefore, the assessment of wild and hatchery trends was further examined using the percentage changes in outmigrating smolt populations of wild and hatchery over years (hatchery plus wild).

Table 9. Percentage of wild and hatchery spring Chinook stocks in juvenile Prosser passage estimates, comparing the hatchery stock to all wild stocks and to the Upper Yakima wild stock by itself.

| Brood Year (BY) | Outmigration Year | Total Yakima Basin |  | Only Upper Yakima River |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | \% <br> Hatchery of Total | \% Wild of Total | \% Hatchery of Upper Yakima Stock | \% Wild of Upper Yakima stock |
| 1997 | 1999 | 24.32\% | 75.68\% | 30.50\% | 69.50\% |

Note: Estimates for the outmigration years from 1998 through 2018 were adopted from Neeley (2019)

We found that while the rate of change in the outmigrating hatchery smolt population over years seemed to be positive (Figure 10) and the trend for wild stocks were negative, the relationship of hatchery passage to wild passage (all wild stocks or only the Upper Yakima wild stock) was not statistically significant. This indicates that the production and releases of spring Chinook hatchery smolts into the upper Yakima do not have an effect on the production of wild smolts. The reduction of the production of wild smolts could be influenced by many factors including habitat loss that limits the carrying capacity and it eventually reduces the survival rate and the total outmigration.

Figure 10. Linear trend on the percentage of hatchery and wild components of the total outmigrating spring Chinook populations for all Yakima Basin stocks and only the Upper Yakima River stock

### 3.6. Genetic variation among stocks (Upper Yakima, Naches, American)

As discussed above, wild Yakima Basin Spring Chinook are comprised of multiple stocks, of which Upper Yakima River, Naches River, and American River stocks have been identified by demographic characteristics and supported by genetic analysis. Reproductively isolated
populations usually differ in productivity. We, therefore, further evaluated whether the rate of outmigration of these genetic stocks has changed over time. Because no hatchery program has been implemented in the American and Naches rivers, we hypothesized that the rate of decline should be higher in the Upper Yakima's wild Spring Chinook, if the hatchery program affected wild productivity.

The annual outmigration estimates showed that the wild Spring Chinook smolt population declined over the 2000-2020 outmigration years (Figure 9) for all three stocks. The rate of decline of the smolt in the Wild Upper Yakima stock was -1529 smolts/year, but the trend was not significant $\left(\mathrm{R}^{2}=0.02, \mathrm{p}=0.469\right)$, nor was the rate of decline for the Naches River stock (Slope $=881 /$ year, $\mathrm{R}^{2}=0.67, \mathrm{p}=0.273$ ). Only the American stock declined significantly (Slope= $1072 /$ year, $\mathrm{R}^{2}=0.228, \mathrm{p}=0.04$, Figure 9 ); there has been no introduction of hatchery smolts into the American River.

In fact, the American River seems to have suffered a relatively low anthropogenic effect compared to the other rivers. It is also the coldest and has entirely natural flow that persists through the summer. If hatchery or other local anthropogenic factors had a negative influence, the American River stock should have declined the least, but the opposite was true in terms of outmigrant abundance.

Figure 11. The relationship between estimated smolt passage of Wild Spring Chinook of Naches, American, and Upper Yakima stock by outmigration year.

### 3.7. Contribution of each stock to outmigration

For outmigration years 1999-2020, about $61 \%$ of the total wild outmigration was contributed by the Upper Yakima wild stock; while $28 \%$ and $11 \%$ were contributed by Naches and American River stocks, respectively (Table 10).

Table 10. American, Naches and Upper Yakima Percentages of Prosser passage of wild Spring Chinook smolts at Prosser Dam. Data for outmigration years 1998 through 2017 were adopted from Neeley (2018).

|  | Outmigration <br> Year |  | Naches | American |

### 3.8. Relationship between Wild Juvenile passage estimates and estimated Adult Returns

Since the number of smolts outmigrating from Prosser (Prosser-passage estimates) varied among years, we further evaluated whether this variation corresponded to adult returns. Or in other words, does the fluctuation of annual wild juvenile passage at Prosser synchronize with the fluctuation of the adult returns at Prosser? To answer the question, we built a univariate relationship between the total Juvenile Prosser estimates of wild Spring Chinook and the predicted adult return to Prosser. Table 12 presents the brood year Prosser escapement (the escapement measures are taken as a surrogate of spawner number) of the parental generation in addition to total juvenile Prosser passage and Prosser return. The relationship between juvenile-to-adult correlation of total wild juvenile passage to adult return from each outmigration was significantly high, with an $\mathrm{R}^{2}$ of $79 \%$ and p value $<0.01$ (Figure 12), indicating that estimated number of outmigration smolts are reasonably accurate.

Table 12. Total estimated escapement (Estimated Spawners (wild/natural) at Yakima river mouth), juvenile passage and return to Prosser of each wild Spring Chinook brood for brood years 1997-2018. Estimated value for the Prosser escapement and Prosser return were adopted from Table 10 and Table 3 of Bosch (2020), respectively. The shaded yellow color indicates that adult returns from these brood years are incomplete.

| Brood <br> Year | Out- <br> migration <br> Year | Estimated <br> Spawners <br> (wild/natural) <br> at Yakima <br> river mouth | Total Juvenile <br> Prosser <br> Passage | Prosser <br> return |

| 2018 | 2020 | 2,451 | 151,265 |  |

Figure 12. The relationship between total smolts outmigration and Prosser returns of progeny (adult returns) of wild Spring Chinook. Since the Spring Chinook can spend as many as 4 years in the ocean, the relationship was made for the populations that outmigrated from 1997 through 2018. Each point is the outmigration year from 1999 to 2018.

Figure 13. Year-to-year trends in juvenile outmigration from Prosser and Adult returns of Spring Chinook (wild) for outmigration years 1999-2018.

### 3.9. Relationship between estimated juvenile passage and river flow

### 3.9.1. Annual

The annual juvenile passage estimate of wild and hatchery Spring Chinook at Prosser Dam tends to increase with average river flow for the outmigration period, but this relationship was significant only for Upper Yakima hatchery smolts (Figure 14).

Figure 14. The relationship between the annual passage estimate for Total Wild, Upper Yakima Wild and Upper Yakima hatchery stocks of juvenile Yakima Spring Chinook and the MarchJune average river flow approaching Prosser Dam. The flow is the sum of the average flow measured at the gaging stations CHCW and YRPW.

### 3.9.2. Daily

The annual juvenile passage estimate of wild and hatchery Spring Chinook at Prosser Dam tends to increase with average river flow for the outmigration period, but this relationship was significant only for Upper Yakima hatchery smolts (Figure 14).

We further evaluated whether the daily estimated number of wild out-migrating smolts in 2020 was affected by daily river flow (the river flow approaching the Prosser Dam, which is the sum of the flow measured at the gaging stations CHCW and YRPW). Figure 15 shows day-to-day trends of the estimated daily counts and the daily river flow and water temperature, and shows that daily estimated outmigrating smolts increased when flow pulses occurred, whether due to natural runoff or reservoir releases made to facilitate outmigration.

Figure 15. Daily estimated counts of hatchery and wild/natural Spring Chinook smolts, water temperature and river flow approaching Prosser Dam for the period in which the CJMF was operated during 2020. The river flow (blue line) is the flow approaching the dam (sum of the flow measured at the gaging stations CHCW and YRPW). Red line is the daily average temperature measured at Prosser.

We analyzed scatter plots and linear relationships between the daily estimated smolt counts of both runs (natural origin and hatchery origin) and daily river flow; and it showed that in general, daily estimated out-migrating smolts was high if the river flow was high (see Figure 16). Furthermore, the smolts were found to be out-migrated more when flow pulse events occurred whether due to natural runoff or reservoir releases made to facilitate outmigration, indicating that when smolt migration appears to be stalled, releases of pulses in flow from reservoirs can improve the rate of smolt out-migration (Figure 15).

Figure 16. The relationship between daily estimated wild/natural and hatchery Spring Chinook smolt passage and river flow approaching Prosser Dam for the period in which the Chandler Canal monitoring facility was operated during 2020.

## Executive Summary

This report summarizes the results of an evaluation to estimate survival rate and travel time of juvenile Spring Chinook Salmon (Oncorhynchus tshawytscha) released into the Roza Dam bypass during 2020. This evaluation is part of an ongoing study that was initiated in 1999. Differences between natural and hatchery rearing environments have a significant influence over the demographic attributes of naturally-spawned and hatchery-origin Chinook salmon beginning in early developmental stages. Moreover, hatchery-origin smolts released into the natural environment experience in-stream conditions that are dramatically different from a controlled hatchery rearing environment. Therefore, attempts to infer the survival rate for natural-origin smolts based on survival of hatchery-reared smolts (or vice versa) can be biased by relative differences in fish size, behaviors such as outmigration timing, fitness, and environmental conditions encountered during outmigration. Our investigation of interannual variation in survival rate and travel time for both natural- and hatchery-origin outmigrating smolts will help managers implement effective strategies for maintaining abundance and viability of the natural spring-run Chinook salmon population in the Upper Yakima River Basin.

In 2020, we tagged 2386 hatchery-origin smolts and 253 natural-origin smolts with passive integrated transponder (PIT) tags at Roza Dam. Tagged fish were released from March $13^{\text {th }}$ through April 30th into the Roza Dam bypass system (ROZ - Release into the Roza Facility Bypass Flume/Pipe). The size of tagged and released hatchery-origin smolts ranged from 82 mm to 169 mm (average 121 mm ). Hatchery fish were significantly larger than PIT-tagged naturalorigin fish, which ranged in size from 78 mm to 135 mm (average 105 mm for Natural-origin smolt).

Our results indicated variable travel times for hatchery- and natural-origin smolts, based on travel between the Roza Diversion Dam's bypass (about 206 kilometers upstream from the mouth of the Yakima River) and the downstream detection site at McNary Dam on the Columbia River 64 rkm downstream from the Yakima River. Fish generally exhibited immediate outmigration behavior after release. In 2020 the travel time from Roza Dam to McNary Dam for natural-origin smolts ranged from 6 to 50 days (mean $\pm$ SE $21.23 \pm 1.18$ days), whereas the travel time for hatchery-origin smolts ranged from 10 to 23 days ( $18.25 \pm 2.95$ days). It indicates that
hatchery smolt took less time to travel to McNary Dam than the natural fish. Mean travel times in 2020 appeared to be shorter for smolts of hatchery origin compared to the 2018 and 2019 outmigration year but natural-origin smolt tooks about 3 days more on average than in 2019 to arrive at McNary Dam. Travel time was positively related with rate of river flow during outmigration, and results of analysis of variance (ANOVA) showed an interaction effect between fish size and origin (hatchery and natural) on travel time. Specifically, hatchery fish which were larger on average exhibited shorter travel times (days to reach McNary Dam) compared to travel times of smaller, natural-origin fish. These results are consistent with Melnychuk et al. (2010) who found that in small rivers, downstream travel speed increased with increasing body length. In addition, downstream outmigration timing and travel days are believed to be affected by many environmental variables, including photoperiod, river discharge, precipitation, lunar phase, air and water temperature, and fish size (Duston and Saunders 1995; McCormick et al. 1995; McCormick 2012; Sykes and Shrimpton 2009; Zydlewski et al. 2014).

In this study, the survival rates from release location to downstream detection at McNary Dam were estimated using the Cormack-Jolly-Seber (CJS) mark-recapture model, which has been commonly used within the Federal Columbia River Power System (FCRPS) to estimate survival rates for juvenile anadromous fish species (salmon and steelhead, see Tuomikoski et al. 2012). The model uses multiple detections of individual marked fish at several dams with PIT-tag detection capabilities. However, survival estimates in prior years (1999 to 2018) were based on a logistic regression model described in the 2018 annual report. We further evaluated the effects of river flow on survival rate by introducing flow as a covariate in the CJS model. Results indicated that survival rate between the Roza Dam release site and the McNary Dam in 2020 was about $38.3 \% \pm 21.0 \%$, but it was different between natural- and hatchery-origin smolts. The survival rate of the natural smolt was found to be $14.2 \% \pm 11.8 \%$ (mean $\pm$ SE), where hatchery smolt had $50.2 \% \pm 34.0 \%$ survival rate. Very few smolts were also found to be detected at McNary Dam for both groups (natural origin-hatchery origin), which resulted in larger error bounds from the mean survival rate.

We further evaluated whether the survival rates of early (tagged and released on or before March 18th) and late (after March 18th) natural-origin and hatchery-origin Spring Chinook were different. The survival rate to McNary Dam of the early release group of natural-origin
$(29.7 \% \pm 2.4 \%)$ was lower than that of the late release group ( $33.8 \% \pm 3.4 \%$ ), but this difference was not significant. Within the late period, when both hatchery- and natural-origin smolts were migrating, the natural-origin survival rate to McNary Dam of ( $33.8 \% \pm 3.4 \%$ ), was significantly higher than the hatchery-origin survival rate ( $27.5 \pm 2.4 \%$ ), suggesting that the superior adaptation of the natural-origin group to outmigration conditions outweighed any negative interactions with their hatchery-origin counterparts.

Results also revealed that survival rate increased with increasing river flow during the downstream migration time but the effect was not significantly different between hatchery- and natural-origin smolts. However, when using mean survival rate of all previous years (21 years, 1999-2020), the survival rate was relatively higher for the natural-origin fish ( $\mathrm{F}_{1,40}=3.22, \mathrm{p}=$ 0.084). Further, we were unable to estimate juvenile survival rates by weekly basis for some of the groups because of high standard errors (SE) in some weeks or because the model failed to converge, indicating insufficient sample sizes for weekly estimates, especially for natural-origin juveniles.

### 1.0 Introduction

In recent years, naturally spawning Pacific salmon populations have declined relative to historical abundances, resulting in many ESA listings and heightened conservation concerns (Prince et al. 2019; Rand et al. 2012; Ford 2011; Gustafson et al. 2007). The recovery of depressed stocks is contingent on obtaining accurate and precise estimates of survival through the hydro system. Juvenile salmon emigrating from the Yakima Basin must navigate downstream through several dams in the Yakima and Columbia rivers during migration to the ocean. For over a decade, hatchery production in Yakima basin has been used to supplement natural salmon populations in order to benefit fisheries opportunities, and to boost declining natural populations. These hatchery programs are likely to continue and possibly increase significantly within the Columbia River Basin (WDFW 2019).

Since 1999, the Yakama Nation has been studying downstream survival of juvenile salmon, with a focus on understanding whether or not survival, and the factors affecting survival, are similar between hatchery-origin and natural-origin groups. The study involves annual releases of hatchery-origin and natural-origin spring Chinook salmon smolts with inserted passive integrated transponder (PIT) tags. There is some evidence to suggest that captive rearing of salmon under certain hatchery protocols (e.g. segregated programs) confers a genetic fitness deficit (domestication) to hatchery fish released into the natural environment compared to naturally reared salmon (Lynch and O’ Hely 2001; Ford 2002; Frankham et al. 2002). While the CESRF program has attempted to minimize differences between hatchery- and natural-origin smolts, artificial rearing environments are still starkly different from the natural in-river conditions fish experience after release. Differences between natural and hatchery rearing environments have a significant influence over the demographic attributes of natural- and hatchery-origin Chinook salmon beginning early in their development. Inferring survival rates for one rearing history based on survival rates for smolts with a different history can be misleading due to differences in fish size, behavior, fitness, and acclimation to environmental conditions encountered during outmigration. In the CESRF program, the desired acclimation window as well as water permit limitations force an emigration window that is different than that of natural-origin fish (YN unpublished data), and this in turn will affect survival rates as flow conditions may vary considerably even on a daily basis depending on weather events. Hatchery-origin smolts are
often larger, likely due to temperature and feed regimens and nutrition content that differ from the temperatures and diet that natural-origin fish experience.

Survival rate may also vary with river flow and fish size during the outmigration period (Zabel and Achord, 2004). Juvenile outmigration is a critical phase in the overall life history of salmon (NPPC, 1992). Mortality rate is likely to increase as a function of migration distance (often hundreds of kilometers), where risk is compounded by exposure to several factors, including predation, extreme temperatures and diseases (Miller et al., 2014), and entrainment at diversions or dams. Furthermore, outmigration is concurrent with the smoltification process, where a fish undergoes physiological, behavioral and biochemical changes in preparation for saltwater habitat (Hoar 1976). Thus, it is important that the coordination between smoltification, outmigration, and arrival time to the estuary be preserved (Folmar and Dickhoff 1980) and remain on schedule with physiological readiness for saltwater.

The timing and duration of outmigration are believed to be affected by many factors, such as fish size, photoperiod, discharge, precipitation, lunar phase, water temperature and type of origin (natural vs. hatchery) (Duston and Saunders 1995; McCormick et al. 1995; McCormick 2012; Sykes and Shrimpton 2009; Zydlewski et al. 2014). In order to determine whether or not downstream survival rate and downstream migration dynamics of Spring Chinook smolts differ between natural and hatchery populations, our study focused on the following objectives:

1) evaluate the survival rate from the release location (Roza Dam) to McNary Dam (McN) between hatchery- and natural-origin smolts based on PIT-tag detections,
2) determine whether, for natural-origin Spring Chinook smolts, there is a significant difference in downstream survival between early outmigrants (sampled and PIT-tagged before the first hatchery-origin smolts appeared in the sample) and late outmigrants (captured during the hatchery smolt outmigration),
3) determine the effect of river flow on survival rate for both groups (hatchery- and naturalorigin), and
4) determine whether or not travel time in the Yakima River differs between natural and hatchery smolts.

### 2.0 Methodology

The Roza Diversion Dam north of Yakima, Washington (Figure 1) withdraws water from the upper Yakima River for irrigation and hydroelectric power. Rotary drum screens and a bypass system return entrained fish to the Yakima River and provide an opportunity to sample and mark fish before they reenter the river. We queried the PTAGIS database (https://www.ptagis.org/) in February 2021 to retrieve available PIT-tag detection information for all Spring Chinook salmon smolts (hatchery- and natural-origin) released at Roza Dam from 2015 through 2020 (Roza bypass; Fig. 1). A total of 2386 hatchery-origin smolts and 253 natural-origin smolts with passive integrated transponder (PIT) tags were released from March 13 through April 30th, 2020 into the Roza bypass system (Fig. 2).

Hatchery-origin juveniles were acclimated at three sites upstream of Roza Dam: Jack Creek in the Teanaway River system, and Easton and Clark Flat on the Yakima River (Figure 1). Naturalorigin and hatchery origin-smolts captured in the Roza bypass were PIT-tagged if not among the 40,000 (about $6 \%$ of the total hatchery release) tagged earlier at the hatchery. Previously-tagged hatchery Spring Chinook were noted as recaptures and included in the Roza release group.

Travel times and survival estimates of PIT-tagged hatchery-origin smolts were compared with those of PIT-tagged natural-origin smolts from the point of release into the Roza Dam bypass to the juvenile detection facilities at McNary Dam. Natural-origin smolts were identified as "early" for those sampled and PIT-tagged before the first hatchery-origin smolts appeared in the sample after their mid-March volitional release from acclimation sites. Natural-origin smolts captured during the hatchery smolt outmigration were assigned to the "late" group. In each release year, survival-estimate comparisons were made between late and early natural smolts, and travel time was measured as the difference between the release date at the Roza bypass and recovery/detection date at the downstream detection facilities at McNary Dam.

Although the survival rate from Roza Dam to McNary Dam in each year from $1999^{+}$through 2018 was estimated using weighted logistic regression (see Neeley, 2018), the survival rates for both groups (natural- and hatchery-origin smolts) for the last 6 years (2015-2020) were estimated

[^12]using the Cormack-Jolly-Seber (CJS) mark-recapture model (see, White and Burnham 1999; Lebreton et al. 1992; Williams et al. 2002; Conner et al. 2015), in accordance with Federal Columbia River Power System (FCRPS) methodology (Tuomikoski 2012). The CJS model uses multiple detections of individual marked fish at several dams equipped with PIT-tag detection capabilities. The assumption of the CJS model is that there is no immigration or emigration during capture and recapture intervals, which is valid in the Columbia Basin hydrosystem (where smolts must pass several hydroelectric dams to reach the ocean) because fish behavior is relatively consistent (all fish are moving in one direction and over a relatively short period; (Conner et al. 2015). The CJS model was originally conceived to calculate time-interval survival of tagged animals by recapturing individuals and estimating survival and recapture probabilities using maximum likelihood. A spatial form of the CJS model can be used for species that migrate uni-directionally and are recaptured/detected within a discrete migratory corridor (Burnham 1987; Henderson et al. 2018). We used individual fish encounter histories to estimate the likelihood that a fish would survive and be detected at the tag detection facility of each hydroelectric dams (Lebreton et al. 1992).

The CJS model was run for different groups by year based on an encounter history constructed from the number of fish released at Roza dam and subsequent detection events at McNary and below McNary Dam (John Day and Bonneville dams). Similar to previous studies (Neeley 2018), all smolt releases were grouped into seven-day periods for analyses. For example, smolts released during ordinal days 1-7 and 8-14 were treated as two distinct release group based on Julian/ordinal period. The estimated survival rates were compared among release groups where the sample sizes were sufficient to provide statistical confidence. In general, every year the volitional exit period from the three Spring Chinook acclimation sites begins March 15, after the natural outmigration is well underway. Natural-origin Spring Chinook smolts captured, PITtagged and released at Roza Dam on March 18th or earlier (Julian date: $<78$ ) were categorized as early releases, and natural-origin captures after March 18 as late releases. This demarcation was based on Spring Chinook counts at the Prosser Dam juvenile monitoring facility downstream from Roza Dam during the 2020 outmigration year, where about $35 \%$ of the natural-origin smolts and none of the hatchery smolts passed Prosser dam on or before March $18^{\text {th }}$.

Analysis of variance (ANOVA) was performed to evaluate differential survival between hatchery- and natural-origin smolts, using group (hatchery-origin vs. natural-origin) and release period (early and late) as factors and years as replicates. There were no PIT-tagged smolts released for this study in 2014 because of a radio-tagging study conducted at Roza Dam. A radio-tagging study was also conducted in 2016, but PIT-tag releases continued on a reduced schedule that year.

Several environmental factors are known to influence downstream smolt survival, and river flow is among the most impactful (Raymond 1968; Connor et al. 2003; Tiffan et al. 2009). We introduced flow rate as a covariate in the CJS model to study its effects. Bureau of Reclamation (BOR) flow data were accessed at:
https://www.usbr.gov/pn/hydromet/yakima/yakwebarcread.html. The average travel time from Roza Dam to McNary Dam averaged about 20 days (combining hatchery-origin and naturalorigin smolts) so each day's release was assigned the 20-day average river flow commencing on the day of release. For example, a fish released on April $1^{\text {st }}$ would reach McNary Dam by about April $20^{\text {th }}$, and the 20-day average flow rate for that time period would be assigned for that fish to determine the effect of river flow on survival.

Several CJS candidate models were built and compared using every possible combination of variables with river flow. Examples of candidate models included (1) two types of temporal variation in survival probability: time variation, which assumed that survival probability $(\psi)$ varies by year; and no time variation which assumed that $\psi$ remains constant for all years; (2) two types of temporal variation in detection probability: time variation, which assumed that detection probability varies by year; and no time variation which assumed that detection remains constant for all years; (3) variation in survival and detection probabilities between natural- and Hatchery-origin, and (4) influence of river flow on the survival and detection probabilities. Altogether, 49 models were built using these combinations (Table 4).

To determine the rank of the different models (49 models), we used the difference in QAICc score relative to the top model. For models with the difference of QAICc (QAICc) $<2$, we selected the model with the lowest QAICs and fewest parameters as the best model (Burnham
and Anderson 2002). We tested the Goodness of Fit (GOF) of competing models using the Bootstrapping Goodness of Fit Approach ("Bootstrap GOF") in program MARK (Cooch and White 2012) to estimate the variance inflation factor for the model constructed to have the most parameters while remaining biologically meaningful (hereafter referred to as the "global model"). All subsequent models were then corrected for over-dispersion using c-hat ( $\hat{\mathbf{c}}$ ). Using the best selected model, we estimated the effect of river flow on downstream survival rate (Roza Dam to McNary Dam) for both groups (hatchery- and natural-origin smolts). The CJS models and program MARK (White and Burnham 1999) were run within the RMark package (Laake and Rexstad 2019) in R statistical software, version 3.3.6 (R Core Team 2019).

Figure 1. The Yakima River Basin showing the three acclimation sites and Roza Dam where natural- and hatchery-origin Spring Chinook smolts were captured, tagged and released. Adapted from Fast et al. (2015).

Figure 2. Number of spring Chinook tagged and released into the Roza dam fish bypass (Hatchery-origin smolt, red; and natural-origin smolt, blue) for each year from 2015-2020. The value on the top of each bar represents the total number of tagged and released smolts on that specific date and year. Hatchery and natural-origin totals are also shown for each year with red for hatchery-origin and green for natural-origin (also see table 1 by groups of 7-days Julian date).

| 140 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| 147 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |  |
| Total | 1432 | 1104 | 1783 | 2578 | 2238 | 2386 | 524 | 136 | 181 | 382 | 292 | 253 |

Note: All smolt releases were also grouped into seven-day periods: i.e., smolt released between Julian dates 1 and 7 were treated as one release period (Group by Julian periods:1), those released between Julian dates 42 and 48 were treated as another release group (Group by Julian periods: 42).

### 3.0 Results and Discussion

### 3.1 Fish sizes

During the last six years (2015-2020), fish with passive integrated transponder (PIT) tags were released for this study from as early as February to as late as May into the Roza bypass system (Figure 2).

In 2020, 2386 hatchery-origin smolts and 253 natural-origin smolts with PIT tags were released. The fork lengths of the released hatchery-origin smolts that were PIT-tagged at the dam ranged from 82 mm to 169 mm (average 121 mm ). Hatchery fish were significantly larger than PITtagged natural-origin fish ( $\mathrm{F}_{1,8}=16.87, \mathrm{p}<0.01$ ), and ranged in fork length from 78 mm to 135 mm (average 105 mm ; figure 3, table 2).

Figure 3. Frequency distribution of fork lengths of hatchery and natural-origin smolts PITtagged and released at Roza Dam.

Table 2. Annual totals of smolts released by origin, their mean and median fork lengths (FL), and standard error (se) around each mean value.

| Released Year | Hatchery-Origin |  |  |  | Natural-Origin |  |  |  |

### 3.2 Yakima River flow below Prosser Dam

Yakima River flow below Prosser dam (gaging station YRPW, which represents the 18kilometer reach between Prosser Dam and the Chandler Power Plant outfall) for monthly 2020 averaged approx. 1338 cubic feet per second (cfs), which was lower than the monthly flow from 2015-2018 but higher than April 2019 (Figure 4, Table 3). However average monthly during spring and summer month was lowest in 2015. For all years, the river flow from June to August was generally less than 800 cfs .

Table 3. Average monthly flow (cfs) and during spring and summer months of the Yakama River at the YRPW gage below Prosser Dam for the years 2015-2020.

|  | Months |  |  |  |  |  |  |  |  |  |  |  |  | Spring \& summer (March-Aug) Average |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 |  |  |
| 2015 | 4793 | 4420 | 2523 | 1043 | 895 | 420 | 387 | 526 | 581 | 892 | 3549 | 5237 | 2106 | 966 |
| 2016 | 2632 | 8603 | 7982 | 8600 | 3437 | 983 | 822 | 519 | 517 | 2086 | 2582 | 1920 | 3390 | 3724 |

| 2020 | 3145 | 4411 | 1470 | 2050 | 2107 | 1241 | 577 | 584 | 693 | 1407 | 2195 | 2120 | 1833 | 1338 |

Figure 4. Average daily flow (cfs, blue line) and 20-day moving average flow (yellow line) of the Yakama River at the YRPW gage below Prosser Dam for calendar years 2015-2020. The red boxes represent the period in which natural- and hatchery-origin Spring Chinook smolts were tagged/released during that year.

### 3.3. Travel time from the release site (Roza Dam) to McNary Dam

The study showed that the travel time (days) of smolts from the release site (Roza Dam) to McNary (McN) dam during the 2020 migration year varied between hatchery- and natural-origin smolts (Figure 5). Most of the smolts were released during the month of April, which is a typical peak outmigration period. As a result, most of the fish generally exhibited immediate outmigration behavior after release. In 2020, one of the hatchery-origin smolts was detected at McNary Dam only 6 days from the date of release at Roza Dam. The travel time from Roza Dam
to McNary Dam for hatchery-origin smolts ranged from 6 to 50 days (mean $\pm$ SE $18.13 \pm 0.9$ days, see table 4); whereas the travel time for natural-origin smolts ranged from 9 to 37 days ( $21 \pm 1.19$ days).

Since the hatchery-origin smolts were larger than natural-origin smolts (figure 6A), size might have played a role in the travel time difference between the hatchery and natural groups. The hatchery smolts took less time to reach McNary Dam than the natural-origin smolts. Previous results have showed that travel time varied among years and the variation might have been related to the variation in river flow among years. In general, the travel time between Roza and McNary dams decreased as river flow increased (Figure 6B).

Survival of juvenile salmon and travel days have been positively related to river discharge (Perry et al., 2018).Travel time was negatively related with river flow during outmigration, and analysis of variance (ANOVA) showed an interaction effect between fish size and origin (hatchery and natural) on travel time. Specifically, hatchery fish, which were larger on average, had shorter travel times to McNary Dam than the smaller, natural-origin fish. These results are found to be consistent with Melnychuk et al. (2010) who found that in small rivers, downstream travel speed increased with increasing body length. In addition, downstream outmigration timing and travel days are believed to be affected by many environmental variables, including photoperiod, river discharge, precipitation, lunar phase, air and water temperature, and fish size (Duston and Saunders 1995; McCormick et al. 1995; McCormick et al. 2000; McCormick 2013; Sykes and Shrimpton 2009; Zydlewski et al. 2013; Zydlewski et al. 2014).

Figure 5. Number of detections of PIT-tagged smolts released at Roza dam from 2015 through 2020 at McNary Dam by release date.

Table 3. The number of observations at McNary Dam (N), mean travel days from the release location to McNary Dam, its standard error (se), and maximum and minimum travel days (range) for both hatchery-origin and natural-origin Spring Chinook smolts by year from 2015-2020.

| Release <br> Year | Natural-Origin |  |  |  | Hatchery -Origin |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Total \# fish (N) | Mean | se | range | Total \# fish (N) | Mean | se | range |
| 2015 | 70 | 30.33 | 1.33 | 9-53 | 44 | 41.41 | 2.02 | 16-76 |
| 2016 | 132 | 13.42 | 0.83 | 3-45 | 12 | 41.00 | 3.06 | 24-62 |
| 2017 | 85 | 19.28 | 1.12 | 4-53 | 3 | 11.00 | 3.06 | 7-17 |
| 2018 | 108 | 24.63 | 0.88 | 5-43 | 17 | 36.71 | 2.90 | 20-60 |
| 2019 | 95 | 17.93 | 0.88 | 4-40 | 14 | 19.00 | 2.49 | 9-37 |
| 2020 | 43 | 21.23 | 1.18 | 6-50 | 4 | 18.25 | 2.95 | 10-23 |

Figure 6. The relationship between travel days from Roza dam to $\mathrm{McNary}(\mathrm{McN})$ dam and fork length at the time of tagging for hatchery- and natural-originSpring Chinook smolts from 20152020 ([A.]); and the relationship between the average travel time (days) from release site (Roza Dam bypass) to McNary Dam and the average river flow below Prosser Dam during the months in which the fish were released ([B.])

### 3.4. Survival rate of hatchery- and natural-origin smolts

Based on the CJS model, the average survival probability from Roza Dam to McNary Dam for the pooled populations (hatchery- and natural-origin smolts combined) released at Roza Dam during 2020 was $38.30 \pm 21.0 \%$ (mean $\pm$ SE), however the hatchery-origin survival rate was 50.2 $\pm 34.0 \%$, which was higher than that of the natural-origin smolts ( $14.2 \pm 11.8 \%$; see Table 3 ). A similar result was observed in 2017 through 2019. The results further showed the standard error of the survival rate in 2020 was larger because fewer fish were detected at downstream dams in 2020 (Table 4). In fact, only 3 smolts were detected at all 3 dams with juvenile detection capability McNary, John Day and Bonneville.

We further evaluated whether the survival rates of early (tagged and released on or before March 18th) and late (after March 18th) natural-origin and hatchery-origin Spring Chinook were different. The survival rate to McNary Dam of the early release group of natural-origin $(29.7 \% \pm 2.4 \%)$ was lower than that of the late release group ( $33.8 \% \pm 3.4 \%$ ), but this difference was not significant (Table 7 and Figure 7B). Within the late period, when both hatchery- and natural-origin smolts were migrating, the natural-origin survival rate to McNary Dam of $(33.8 \% \pm 3.4 \%)$, ) was significantly higher than the hatchery-origin survival rate ( $27.5 \pm 2.4 \%$; Figure 7A and Table 7), suggesting that the superior adaptation of the natural-origin group to outmigration conditions outweighed any negative interactions with their hatchery-origin counterparts.

Table 4. Released and detected populations at McNary (McN) and Bonneville (BON) Dams and Roza-to-McNary survival rate for all ("All": pooled hatchery- and natural-origin), hatcheryorigin, and natural-origin smolts for the years 2015-2020. Note: there were 5 detection-history combinations and each group ( Detection histories) is represented by the release-detection sequence and the number of fish detected in that sequence. "1-0-0" corresponds to release at Roza dam (1) but no detections at McNary (0) or Bonneville (0) dams. Similarly, "1-0-1" represents the number of fish released at Roza dam (1), not detected at McNary (0), but detected at Bonneville. The remaining two sequences for each year represent detection only at McNary, and detection at both McNary and Bonneville.

| Year | Detection histories | Number of PitTags by Type |  |  |

*** indicates the models failed to converge so that the survival rate could not be estimated.

Figure 7. The box plot showing the 22-year average survival probabilities of natural-origin (Natural) and hatchery-origin (Hatchery) Spring Chinook smolts (see Table 7 for the data). A. is the comparison of Late hatchery- and natural-origin smolts; and B . is the comparison between Early and Late natural-origin smolts.

### 3.5. Effect of river flow on survival rate

We further evaluated whether river flow affects the outmigration survival rate for hatchery- and natural-origin smolts. Among the 49 models shown in Table 6, the model that included an effect of river flow on the survival rate for the groups but varied by years had the lowest QAICs and therefore was selected to illustrate the effects of river flow on survival. Based on the best model, the survival rate between Roza and McNary dams was positively related with the river flows for the years 2015-2020 (Table 6 and Figure 8). This result is consistent with the previous results as that smolt migration and dam passage survival were positively correlated with stream flow because higher flows increase migration rates, potentially reducing exposure to predation, and reduce delays in reservoirs (see, Courter et al., 2016).

Table 5. The top 20 candidate models of the 49 candidate models, and associated statistical parameters. The models are ranked based on Quasi-likelihood Akaike's Information Criterion adjusted for over-dispersion $\left(\mathrm{QAIC}_{c}\right)$. The model with the lowest $\mathrm{QAIC}_{c}$ value was considered 'best'. "Wt" represents the weight of the model. S and p represent survival and capture probability, respectively, while "npar" represents the number of parameters used in the model. The models were built using 2015-2020 data.

| SN | Models | npar | QAICc | Delta( $\Delta$ ) | Wt |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | S( $\sim$ Year + riverFlow) p( Year:RearType + riverFlow) | 20 | 6993.68 | 0.00 | 0.46 |

Figure 8. The predicted survival rate as a function of river flow based on the best CJS models ("S( $\sim$ Year + riverFlow) p( $\sim$ Year:RearType + riverFlow)"; Table 5). The shaded area is the standard error of the predicted mean.

### 3.6. Comparison of Natural- and Hatchery-Origin Smolt Survival to McNary

 Dam of Roza releases during the "Late" release periodYearly survival estimates based on all contemporaneous late-period smolt are given in Table 7 and Figure 9A (top panel). Because natural-origin smolts have spent more time in the natural habitat than hatchery-origin smolts by the time fish pass Roza Dam, it has always been hypothesized that, for smolt contemporaneously released at Roza, the survival to McNary of natural-origin smolt would be greater than that of hatcheryspawned smolt even though the hatchery-origin fish tend to be larger. However, in 2020, the survival rate of hatchery-origin smolts was greater than that of natural-origin smolts
(fig. 9A) and a similar result was observed in 2017 and 2018. However, when using mean survival rate of all previous years (21 years, 1999-2020), the survival rate was higher for the natural-origin fish $\left(\mathrm{F}_{1,40}=3.218, \mathrm{p}=0.08\right)($ Figure 7 A$)$.

Table 7. Survival of Spring Chinook smolts from Roza Dam to McNary Dam by origin, release year and release period, showing the number released ( N ), the survival probability, and the standard error of the survival probability (SE; 2020 only) for each release group.

| Year | Natural-Origin |  |  |  |  |  | Hatchery-Origin |  |  |  |  |  |

Note: estimates for the years 1999-2018 are from Neeley 2019. * SE is very high indicating high uncertainty of the estimated value (low precision).

### 3.7. Comparison of Early and Late Natural-Origin Smolt Survival to McNary Dam

There were no early natural-origin fish releases at Roza prior to passage of hatcheryorigin smolt in 1999, 2010, 2017, 2019, 2020; and, as stated earlier, there were no PITtagged releases at Roza Dam in 2014. Table 6 and Figure 9B present the natural-origin early and late smolt survivals from Roza to McNary for all years. Of the 18 years with early releases, late releases had greater Roza-to-McNary survival than early releases but the difference was not statistically significant ( $\mathrm{F}_{1,36}=1.524$, $\mathrm{p}=0.22$, Fig 7 B ). In general, earlier outmigrants are believed to have a greater survival rate. However, the results showed that later releases had higher survival rates, although not significantly higher. A lower survival rate for earlier releases could be due to a lower proportion of out-migrants entering juvenile bypass systems where PIT tags can be detected. Generally, McNary Dam's bypass is watered up after Julian date 90 (March $30^{\text {th }}$ ), so fish passing earlier would be spilled rather than bypassed, resulting in a lower detection rate, consequently survival rate is also lower. It may also be that some of the early natural-origin releases pass McNary Dam before they could be detected in McNary's bypass, in which case the early-release natural survival estimates presented here may be underestimated.

### 3.8. Weekly survival rate of natural- and hatchery-origin Smolt

The survival rate (Roza-McNary Dam) varied by week for both groups (natural- and hatchery-origin), however the number of natural-origin releases were not sufficient to estimate the weekly survival rate with statistical confidence. In general, the hatcheryorigin smolts that were released early [Julian date 91, which was the week of April 1st to $\left.7^{\text {th }}, 2020\right)$ had higher survival rate $(78.21 \% \pm 7.4 \%)$ than the smolts released during the week [Julian date 126] between May 7 and May $12^{\text {th }}, 2020$ ( $27.2 \pm 14.88 \%$, see table 7 and figure 10).

Figure 9. Bar-diagram of Upper-Yakima Spring-Chinook Roza to-McNary Smolt-toSmolt Survival for Late Natural- and Hatchery-Origin juvenile for each release year (1999-2020). A. is the comparison of Late hatchery- and Late Natural-origin smolt; and B. is the comparison between Early and Late Natural-origin Smolt.

Table 8. Roza-Dam to McNary-Detection Smolt-to-Smolt Survival probability with respect to Julian week. "Sur" and " N " represent survival probability and the number of smolts tagged and released, respectively.

| Origin | Param eter | Julian Date |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  | Early | Late | Over <br> All |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

### 4.0 Acknowledgment

We thank all of the crews whose collective fish-tagging efforts over the years made this study possible. We are also grateful to Andrew Matala and David Lind who reviewed and provided valuable comments in the draft report. We would also like to thank Daylen Isaac who provided the hydrological data.

## Executive Summary

Coho salmon (Oncorbyncbus kisutch) in the Yakima basin were extirpated in the early 1980s but reintroduction efforts initiated in the mid-1980s have resulted in hatchery-produced coho naturally reproducing in both the Yakima and Naches rivers. In 1984 there was no escapement ( $\mathrm{n}=0$ ) of adult Coho Salmon returning to the Yakima Basin, but the return of hatchery-produced origin fish peaked in 2014 (> 25,000 adults). Several release strategies for outplanting fish have been implemented in the reintroduction program to evaluate and compare relative survival and escapement. Outplants have been released at both the parr and smolt life stages, including different size classes, released at multiple locations, including different release dates, and outplanted from different broodstock sources. A diverse strategic approach has been utilized to maximize the likelihood of achieving stable and abundant returns of natural-origin Coho salmon to the Yakima River and to enhance the stability and resiliency of the population against potential environmental changes.

An ongoing, long-term monitoring program is being conducted with the aim of improving project objectives and strategies by applying what is learned from the project experiments, monitoring and evaluation, and literature reviews in an adaptive management framework. This evaluation is an annual update of ongoing monitoring that began with the first reintroduction efforts in 1996. The report summarizes the estimated survival rate and travel time of juvenile (smolt and parr) Coho salmon releases from multiple locations in the Yakima basin with a focus on the following objectives:

- Determining survival rate and travel time of smolts released in 2020 and parr released in 2019 (migration year 2020) and quantifying annual trends
- Comparing survival rates between outplants from different broodstock sources (Yakimaorigin vs. outplants from Eagle Creek National Fish Hatchery and Washhougal Hatchery)
- Identifying watershed-specific survival rates between the upper Yakima River and Naches River release locations for out-migrating juveniles, and identifying whether survival rate differs as a function of release month (February, March or April)
- Evaluating the effects of Yakima River flow (using average flow at Prosser Dam for the summer months) on outmigration survival rate
- Evaluating Smolt-Adult return (SAR) percentage for Coho released as parr and as smolts each year for outmigration years 2004-2020
- Determining the age composition of the coho returns from ocean at Bonneville Dam for Coho released as parr and those released as smolts

## Sample size and fish size

In 2020, a total 13845 PIT-tagged smolts were released in the Yakima Basin. Among the PIT-tagged smolts, the brood source for 9954 tagged smolts was Eagle Creek NFH with 2952 tagged smolts originating from Yakima Basin returns. Both stocks were reared in Prosser Hatchery and released in the Yakima River at Prosser Dam on March 27, 2020. Another 939 tagged Yakima-origin smolts were reared at Prosser Hatchery and released in the lower Yakima Basin at Ahtanum Creek on Feb 18, 2020. Regarding parr for migration year 2020, 1289 tagged parr were released into the Naches River near the Tieton River confluence in 2019 (8/9/2019). During 2020, 1249 tagged parr were released in the upper mainstem Yakima River near the Holmes acclimation site near Ellensburg WA in August of 2020, but this parr release group is not included in this report because they start to outmigrate only in 2021. Although a total 13845 smolts and 2538 parr were PIT-tagged for this (2020) migration year, fish length information was available only 79 fish and all of which were released at Prosser Dam. Based on the available data, the length of the smolts released at Prosser was $105.35 \pm$ 0.89 mm at the time of tagging.

## Travel time to McNary Dam

Most of the 2020 smolts were released at Prosser Dam. The average mean travel time from Prosser Dam to McNary Dam was about $32.96 \pm 8.93$ days; whereas in 2019 it was $21.32 \pm 8.54$ days. The variation in travel time among years can be associated with several in-river conditions including variation in river flow, water temperature or release time. Besides the Prosser Dam release, relatively few smolts ( 939 smolts with PIT tags) were released from Ahtanum Creek, and none of the released fish were detected at McNary Dam so that it was not possible to compare the travel times among release locations for the 2020 migration year. For the parr release group, the 2019 Upper Yakima River parr outmigrating in 2020 were detected at McNary Dam 288 days $\pm 12.5$ days (mean $\pm$ SE; range 276 days to 301 days) after release. In previous years (2015-2019), fish released at Prosser Dam exhibited the shortest travel time to McNary Dam, whereas the Jack Creek release group from the upper Yakima Basin had the longest travel time (mean $47.14 \pm 4.59$ days). Travel times for the
groups released at the Easton, Holmes and Stiles ponds, Wenas Lake, and Ahtanum Creek ranged from 33 to 39 days.

## McNary Dam detection rate

The overall smolt detection rate at McNary Dam was $4.31 \% \pm 0.58 \%$ in migration year 2020, which was slightly lower than the detection rate of $6.23 \% \pm 0.9 \%$ in 2019. In general McNary detection rates varied among years. The highest detection rate was in 2016 ( $24.63 \pm 1.51 \%$ ) and the lowest was in 2020 ( $4.31 \% \pm 0.58 \%$ ). Variation in the detection rate at McNary Dam might be due to river flow, spill percentage and how surface-passage structures were operated. Similar to smolt releases, detection rates at McNary Dam for parr releases were also variable among years.

## Release-McNary Juvenile survival rate

The average survival probability of juvenile Coho Salmon smolts from the release sites to McNary Dam in 2020 was $47.14 \pm 5.78 \%$, which was higher than the 2019 estimate ( $14.27 \pm 2.64 \%$ ), the 2018 estimate ( $24.51 \pm 3.2 \%$ ) and the 2017 estimate ( $29.06 \pm 3.4 \%$ ). The higher survival rate for 2020 migration is at least partly due to release location because most of the tagged smolts in 2020 were released at Prosser Dam in the lower Yakima River. In other years, smolts were also released from several locations upstream from Prosser Dam, with correspondingly lower survival rates.

The survival rate of smolts to McNary Dam was higher for the Eagle Creek-stock releases (52.6 $\pm$ $7.4 \%$ ) than for Yakima-origin release ( $41.1 \pm 10.1 \%$ ). In 2019 and 2020, there was no release of the Washougal stock, but survival rate for the data pooled from 2015 to 2020 by stocks the highest survival rate was for Eagle Creek smolts and the lowest was for Washougal smolts, with Yakimaorigin smolts in the middle of the survival range.

We further evaluated whether there was an effect of hatchery environment on survival rate. Yakimaorigin smolts were released in two groups from Stiles Pond on the same date in 2016. One group had been reared at Eagle Creek Hatchery and the other at Prosser Hatchery. Survival rate (Stiles to McNary Dam) was higher for the smolts reared at Eagle Creek Hatchery ( $35.26 \pm 4.14$, mean $\pm$ SE ) than for those reared at Prosser hatchery ( $13.28 \pm 1.49$, mean $\pm$ SE), which suggests a hatchery effect, which could arise from many factors including water temperature and water quality. Fish sizes would have aided the comparison but were not available.

Since smolts were released over a three-month period (February, March and April), release date might also have affected survival because of the variation of the habitat quality or quantity including water temperature and river flow. The effects of river flow and release month were introduced as covariates in the CJS model using survival data from 2015-2020 releases. Smolts released in March had a higher survival rate compared to February and April, and higher flow during the 20-day period following release improved survival in all release months.

For parr released during the 2020 migration year, releases occurred only in in the lower Yakima River at Ahtanum Creek in 2019 but the very low number of fish detected at McNary Dam indicated that the survival rate for parr migrating in 2020 was also very low. For the last 6 migration years (20152020), Coho parr were released at different locations from May to October. Release site-to-McNary survival of the parr releases was higher for the population released in August ( $14 \% \pm 0.20$ ) and followed by the group of July releases $(3.1 \% \pm 0.40)$ and then June releases $(1 \% \pm 0.4)$.

## The Smolt-to-Adult Return (SAR) percentage

The percentage of smolts that survive and return (SAR) to spawn is important because it incorporates cumulative impacts of the freshwater habitat, hydrosystem and ocean conditions that determine the sustainability of adult returns over time. In this study, SARs were based on the percentage of smolts detected at McNary Dam that returned as adults to Bonneville Dam. Since Coho can spend as many as 3 years in the ocean, we estimated SAR for the populations that outmigrated from 2004 through 2018 for both parr and smolt releases.

The results showed that the (McNary-to-Bonneville) SAR estimates varied by year and life stage at release during the 15 -year study period. On average, the SAR was slightly higher for the group released as parr (SAR: $3.98 \pm 1.06 \%$ ) than the SAR for the group released as smolts (SAR: $3.79 \pm 1.06 \%)$. The highest SAR for the group released as parr was in migration year 2018 ( $8.75 \%$ $\pm 1.66 \%)$, followed by the groups released in 2013 ( $7.56 \pm 1.23 \%$ ) and 2008 ( $6.85 \pm 1.04 \%$ ), but lowest in migration year $2006(0 \%)$. For smolts, the highest SAR was for the group released in 2008 ( $8.28 \pm 0.25 \%$ ), followed by 2013 ( $8.08 \pm 0.91 \%$ ) and 2010 ( $6.48 \pm 1.14 \%$ ), while the lowest SAR was in 2011 ( $0.85 \pm 0.25 \%$ ). The variation in SARs among years can be associated with many factors such as smolt size, release and ocean entry timing, and ocean conditions.

## Returning adult age composition

For outmigration years 2004 through 2019, a total of 3194 returning PIT-tagged Coho released as smolts and 1459 returning Coho released as parr in the Yakima Basin were detected at Bonneville Dam. For the adult returning group released as smolts, $\sim 85 \%$ of were age 3 (ocean age 1), $9 \%$ were age 2 (ocean age 0 ), and $7 \%$ were age 4 (ocean age 2). For the group released as parr, $90 \%$ of retuning Coho were age $3,10 \%$ were age 2 , and none were age 4 .

## 1. Introduction

Prior to their extirpation in the early 1980's, Yakima Basin Coho salmon (Oncorbynchus kisutch) were once widely distributed among tributaries of the Yakima and Naches rivers (Fulton 1970; Chapman 1986), with annual adult returns numbering from 44,000 to 150,000 (Kreeger and McNeil 1993). Releases of hatchery reared Coho salmon in the Yakima Basin began in 1983 with the first release of 324,000 smolts originating from the Little White Salmon Hatchery (YN 1997). In 1988, the Yakama Nation (YN) and the Washington Department of Fish and Wildlife (WDFW) developed and implemented a reintroduction program that has successfully shown evidence of natural production in both the Yakima and Naches rivers. The highest return of adults (2014) from hatchery releases and natural production was greater than 25,000 fish.

Several alternative release strategies have been utilized in the reintroduction program over time in response to observations in long-term monitoring. Smolts were initially released in the mainstem of the Yakima River (Dunnigan et al. 2002), but subsequent releases have explored a range of different locations to understand how geographically and hydrologically diverse habitats within the Yakima Basin affect outmigration survival and adult returns. Habitat capacity and quality have a significant impact on growth rate and survival, and within the Yakima River Basin human alterations to the environment continue to exacerbate naturally limiting conditions by reducing the quality and quantity of available spawning and rearing habitat. On the other hand, broad habitat restoration programs are concurrently being implemented to improve habitat conditions in many Yakima Basin streams. Other exploratory release strategies have included variable life stages (parr vs. smolts) at release, different release times, and use of multiple outplant sources. In past years, the primary sources of Coho outplants have been Yakima Basin returns, Eagle Creek National Fish Hatchery and WDFW's Washhougal Hatchery. In total, about 500,000 juvenile coho have been released each year from permanent acclimation sites or from temporary mobile acclimation facilities operated in upstream locations in tributary streams of the Naches and upper Yakima rivers.

Columbia River Coho typically spend one year in freshwater before out-migrating as yearling smolts (typically in April and May), then spend two growing seasons (about 18 months) in the ocean before returning as 3-year-old adults (Hassler 1987) to spawn in their natal streams (Beamish et al. 2004). Precocious, sexually mature males (jacks) may also return to spawn after a summer at ocean. Adult Coho generally migrate upstream at water temperature ranging from $7.2^{\circ} \mathrm{C}$ to $15.6^{\circ} \mathrm{C}$ (Reiser and

Bjornn 1979 cited in Laufle et al. 1986) and spawn from late October to November, sometimes as late as December or January.

Spawning normally occurs in transitions from pools or runs to riffles, in minimum water depth of 0.18 m , at water temperatures ranging from $4.4^{\circ} \mathrm{C}$ to $9.4^{\circ} \mathrm{C}$, and velocities ranging from 0.3 to 0.91 $\mathrm{m} / \mathrm{sec}$ (Thompson 1972, BOR 2007). The optimum temperature for coho salmon egg incubation was $4^{\circ} \mathrm{C}$ to $11^{\circ} \mathrm{C}$ (Davidson and Hutchinson 1938, cited in Sandercock 1991). Juvenile coho salmon survive best in low-gradient habitats (generally less than four percent; Jones and Moore 1999) and tributaries with a stream gradient less than $3 \%$ with complex and deep pools or beaver ponds (Bradford et al. 1997 and Reeves et al. 1989).

An ongoing, long-term monitoring program is being conducted with the aim of monitoring progress towards project objectives and improving strategies by applying what is learned from the project experiments, monitoring and evaluation, and literature reviews in the Yakima-Klickitat Fisheries Project adaptive management policy. This report is an annual update of an ongoing monitoring effort that began in 2001. It summarizes survival rate and travel time estimates for juvenile Coho parr and smolts released from multiple locations in the Yakima basin, with a focus on the following objectives:

* Determining survival rate and travel time of smolts released in 2020 and parr released in 2019 (migration year 2020)
* Comparing survival rates between outplants from different broodstock sources: Yakima returns vs. outplants either from Eagle Creek National Fish Hatchery or Washougal Hatchery
* Identifying watershed-specific survival rates among upper Yakima basin and Naches basin locations for out-migrating juveniles, and identifying whether survival differs as a function of release month (February, March, April)
* Evaluating the effects of river flow on outmigration survival rate
* Determining the annual Smolt-Adult return (SAR) from 2004-2020 and age compositions of the adult returns

## 2. Methodology

### 2.1 Geographical distribution: historical and current

Coho salmon were native to the Yakima River basin and its spawning area was quite widespread in the Yakima River basin, including the Bumping River (Wydoski and Whitney 2003; Tuck 1995). Historically, it was assumed that Coho were present in low-gradient streams in the Yakima Basin prior to extensive habitat alteration and were widely distributed among tributaries of the Yakima and Naches rivers (Haring 2001; Berg and Fast 2001; Figure 1A). Acclimation and release sites designated in the reintroduction program overlap this historical geographical distribution (Figure 1B).

Figure 1. Historical Cobo geographical distribution and recent reintroductions.

## B. Coho smolt and parr release sites, 2008-2020

### 2.2 Fish PIT-tag Data

We queried the PTAGIS database (https://www.ptagis.org/) in May 2021 to retrieve available PITtag detection information for all Coho Salmon smolts released at the different locations in the Yakima Basin from 2015 to 2020 (Figure 1). Numbers of PIT-tagged fish released each year among sites in the Yakima Basin ranged from 13,865 in 2020 to 20,305 in 2019 (Figure 1, Table 1).

Two stocks (Yakima and Eagle Creek) were released from Prosser and Ahtanum creek on Feb 18 and March 27, 2020 for outmigration year 2020. Fish were released at only two sites because of restrictions associated with the COVID pandemic. A total of 2952 and 939 PIT-tagged smolts of the

Yakima stock were released in 2020 at Prosser Dam and Ahtanum Creek on the La Salle High School grounds, respectively. A total of 9874 PIT-tagged smolts from Eagle Creek Hatchery were released at Prosser Dam in 2020 (Table 1).

Table 1: Broodstock sources, juvenile rearing facilities, release sites and counts of PIT-tagged smolts released in outmigration years 2015 to 2020.

Unlike smolts, which begin emigration immediately after release, parr typically outmigrate as yearling smolts in the spring following their release, so Coho parr released in 2019 were evaluated for migration year 2020. A total of 1289 PIT-tagged Coho parr were released into the Tieton River of the Naches Subbasin in 2019 (migration year 2020, Table 2). The total release and the number of release sites were much smaller and fewer than in previous years as shown in Table 2. There were no parr releases for migration year 2017.

Table 2: Coho parr releases by migration year from 2015-2020. Parr were released one year earlier than the designated migration year.

| Sub-basin | Release Location | Migration Year |  |  |  |  |

### 2.3 Data analyses

Travel times and survival rates for both parr and smolt releases from the different release locations to McNary Dam were estimated each year from 2015 to 2020. Travel time was estimated as the difference between the date of release and the date of detection at McNary Dam.

For outmigration years 2007 through 2018 a logistic regression model (Neeley 2012) was used to estimate survival probability of the groups. Beginning in 2019 and in this report, survival probability from release locations to McNary Dam and detection rate of the released PIT-tagged Coho smolts at McNary Dam were estimated using the Cormack-Jolly-Seber (CJS) mark-recapture model (see, White and Burnham 1999; Lebreton et al. 1992; Williams, et al. 2002, Conner et al. 2015), which has been commonly used within the Federal Columbia River Power System (FCRPS) to estimate survival
rates for juvenile anadromous fish species (Tuomikoski et al. 2013). The model uses multiple detections of individually marked fish at several dams with PIT-tag detection capabilities.

Among the several assumptions of the CJS model, one assumption is no immigration or emigration during capture (tagging) and recapture (detection) intervals, which is valid in the hydrosystem because of necessary passage at several hydroelectric dams, and where fish behavior is relatively consistent as fish are moving in one direction over a relatively short period of time (see; Conner et al. 2015). The CJS model was originally formulated to calculate time-interval survival of tagged animals by recapturing individuals and estimating their survival and recapture probabilities using maximum likelihood. A spatial form of the CJS model can be used for species that migrate unidirectionally, and are recaptured/detected within a discrete migratory corridor (Henderson et al. 2018, Burnham 1987). We used individual fish encounter histories to estimate the likelihood that a fish would survive and be detected at each tag receiver facility (dams in this study; see Lebreton et al. 1992). The CJS model was run for all smolts released at each location based on an encounter history constructed from the number of fish released at the different locations and subsequent detection events at McNary, John Day and Bonneville dams on the Columbia River. Similar to previous studies (Neeley 2018), we estimated the survival rate and detection efficiencies for each release group and broodstock source.

Several environmental factors are known to influence downstream smolt survival, and river flow is among the most impactful (Raymond 1968; Connor et al. 2003; Tiffan et al. 2009). Since early and late release groups presumably experience variable flow regimes in the Yakima River, each is likely to incur a different rate of survival associated with temporal river conditions. Therefore, it was necessary to introduce both river flow and release month as covariates in the CJS model to estimate the survival rate of the releases. In the model we used the last six years of data (2015-2020) to increase the overall sample size and confidence around our estimates. Fish were released from February through May with multiple releases in each year (2015-2020); however, in 2015, a drought year, a negligible number (6) of PIT-tagged Coho were released in May, and we excluded this release and evaluated release month effects for February through April in 2015.

Flow data for the Yakima River below Prosser Dam (YRPW) were accessed from the Bureau of Reclamation website at: https://www.usbr.gov/pn/hydromet/yakima/yakwebarcread.html. The average travel time from Prosser to McNary Dam was approximately 20 days. Accordingly, a 20-day
moving average of river flow data was assigned to each tag PIT-tagged fish to determine the effect of river flow on survival rate of the release group.

Several candidate CJS models were built using every possible combination of river flow and release month, with varying or constant survival and detection probabilities at dams in the CJS models. To determine the rank of the different candidate models we used the difference in the QAICc ( $\Delta$ QAICc: Quasi-likelihood AICc Akaike's information criterion difference) relative to the top model. For models with $\Delta$ QAICc $<2$, we selected the model with the lowest QAIC and fewest parameters as the best model (Burnham and Anderson 2002). Selecting the best model, we estimated the effect of river flow on downstream survival rate for each release group. The CJS models were run within the RMark package (Laake and Rexstad 2019) in R statistical software, version 3.3.6 (R Core Team 2019). More information about the model is available in in Pandit et al. 2020 (Appendix D of Bosch et al., 2020).

### 2.4 The Smolt-to-Adult Returns (SAR)

SAR, which is the percentage of smolts that survive and return as an adult to spawn, is a metric that captures most of the cumulative impacts of the hydro-system and ocean conditions on anadromous fish, indicating how sustainable the returns of adults are over time. The SAR was estimated as the percentage of smolts detected at McNary Dam returning as adults to Bonneville Dam using the following equation for each year and release group:

$$
\cup_{\text {at } M c N \& B O N} / J_{a t M c N}
$$

Where, $\mathrm{U}_{\mathrm{at} \text { MCN \& BON }}$ is a total number of PIT tagged fish which were detected at McNary Dam $(\mathrm{McN})$ as a juvenile and also detected at Bonneville Dam (BON) as a returning adult (joint detection). Jat McN is the total number of fish detected at McNary Dam as juveniles. Since Coho can spend as many as 3 years in the ocean, we estimated SAR for the populations that out-migrated from 2004 through 2018 for both groups (released as parr and smolt). Nonparametric $90 \%$ confidence intervals were computed around the estimated annual overall SARs for each group as described by McCann et al. (2020). The nonparametric bootstrapping approach of Efron and Tibshirani (1993) was used where first, the point estimates were calculated from the sample for each population, and then the data were re-sampled, with replacement, to create 1,000 simulated samples (Berggren et al. 2002, Chapter 4). These 1,000 iterations are used to produce a distribution of annual SARs from
which the value in the 50th ranking is the lower limit and value in the 950th ranking is the upper limit of the resulting $95 \%$ nonparametric confidence interval.

### 2.5 Age composition of adult returns

The ocean age of each returning Coho was estimated by subtracting the date of detection at the Bonneville Adult passage from the date of release. Coho smolt and parr releases naturally show different outmigration behavior after release. Coho smolts start to migrate downstream immediately after release, while parr typically outmigrate as yearling smolts in the spring following release in summer/Fall. Therefore, for parr release groups, ocean age was estimated as:

1. Ocean age of parr $=$ date of detection of returning adult at Bonneville Dam - release date 365 days;
whereas the ocean age of the smolt was estimated as:
2. Ocean age of smolt $=$ date of detection of returning adult at Bonneville Dam - release date

Return age composition was estimated as the proportion of each age class of adult return detected at Bonneville Dam for each brood year and life stage.

## 3. Results and Discussion

### 3.1 Fish size (Fork length) at the time of tagging and release

Among the 111,418 Coho smolts released with PIT-tags from outmigration years 2015 through 2020, lengths at the time of tagging were available for only 8605 fish ( $7 \%$; Table 3). The broodstock sources of these smolts were Yakima returns, Eagle Creek outplants and Washougal outplants released in March and April of each outmigration year. Overall, there was no significant difference in mean smolt fork length among release groups in different months, but fish released in March tended to be larger at tagging than fish in the April release groups. This was contrary to expectations since fish should be growing larger over time. This was most likely a hatchery effect, as March releases were largely comprised of fish reared at the Prosser hatchery where water temperatures are higher than at the other hatcheries used to rear Coho juveniles for this study.

For the 2020 migration year only, a total 13845 smolts $(9954+2952+939)$ and 1289 parr were released but fish length information was available only for 79 of the PIT-tagged Coho smolts released at Prosser. The mean length of the smolts in this small sample was $105.35 \pm 0.89 \mathrm{~mm}$ at the time of tagging. Since the fish of the Ahtanum releases had not been measured, the length at tagging could not be evaluated.

Table 3: Smolt fork length by year, release location and release month, with sample size (n). Data are based on the limited data available from PITAGIS ( $\mathrm{n}=8605$ out of 111,418 total tags).

|  | Release | Release |  | Mean |  |  | Range |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| 2019 | Stiles | April | 442 | 100.22 | 0.52 | 67 | 126 |
| 2020 | Prosser | March | 79 | 105.35 | 0.89 | 80 | 123 |

### 3.2 Travel Time from Release Locations to McNary Dam

Most of the 2020 migration-year Coho smolts were released from Prosser Dam, and only 939 smolts (7\%) were released from Ahtanum Creek. For the group released at Prosser, its mean travel time to McNary Dam was 32 days $\pm 8.93$ days (see table 4A), which was about 11 days more than 2019 (it was only $21.32 \pm 8.54$ days in 2019 migration year). Variation in travel time among years can be associated with several in-river conditions including variation in river flow, water temperature, release timing, or fish size. Other in-river conditions can also affect movements, such as hydroelectric dams and their impoundments on the Columbia River, especially for smaller or not fully-smolted juveniles. The 2019 Prosser group was released on April 02, 2019 and the 2020 Prosser group was released March 27, 2020, which was about 5 days later during 2020 out-migration year than 2019 outmigration year.

None of the 939 smolts released from Ahtanum Creek were detected at McNary Dam, so it was not possible to compare travel times among release locations for the 2020 outmigration year. However, based on the 2015-2019 outmigration years for the evaluation of release sites, fish released at Prosser Dam exhibited the shortest travel time to McNary Dam (mean $21.32 \pm 8.54$ days), whereas the group from Jack Creek, released 234 river kilometers upstream from Prosser Dam, had the longest travel time (mean $47.14 \pm 4.59$ days). Travel times for the groups released at the Easton, Holmes and Stiles ponds, Wenas Lake, and Ahtanum Creek, all upstream from Prosser Dam, ranged from 33 to 39 days.

Coho parr released in 2019 and outmigrating in 2020 were detected at McNary Dam after 288 days $\pm$ 12.5 days (mean $\pm$ SE) following release in 2019, ranging from a minimum of 276 days to a maximum of 301 days (Table 4B).

Table 4. Travel time from release site to McNary Dam for [A] smolt releases, and [B] parr releases.
A. Average travel days from release location to McNary Dam for smolt

B. Average travel days from release location to McNary Dam for parr

| Sub-basin | Release Location | Migration Year |  |  |  |  |

### 3.3 Detection rate of smolt releases at McNary Dam

For 2020 outmigration year, a total of 13845 Coho were released as smolts from Prosser Dam in 2020 and 1289 were released as parr in the Naches River in 2019. Only a small proportion of smolts passing McNary Dam were detected at McNary Dam. The overall detection rate of the smolts at McNary Dam was $4.31 \% \pm 0.58 \%$, which indicates that with $95 \%$ confidence the true detection rate of can be found between $3.17 \%$ and $5.45 \%$ (Table 5a). A very few of the parr released in 2019 were detected at McNary Dam during migration year 2020, and the detection rate was $25.00 \% \pm 21.65 \%$, in which standard error was very high ( $\pm 21.65 \%$ ). It indicates that the uncertainty of the estimated detection rate is large, which might be due to a combination of factors such as lower sample size and higher mortality during the extended period between release and outmigration (Table 5b).

When evaluating detection rate at McNary Dam from 2016 through 2020, it was found that the detection rate varied by year. The highest rate was in 2016 and the lowest detection rates were in 2016 and 2020 (see Table 5). The variation in the detection rate at McNary Dam can be due to how
surface-passage structures are operated. In recent years, increasing spill and the use of surfacepassage structures (spillway weirs) at dams are a primary management strategy to increase survival of juvenile fish passing dams within the Federal Columbia River Power System. Greater use of spillways results in a lower proportion of fish entering juvenile bypass systems where PIT tags can be detected (Widener et al. 2018), and fluctuations in spill and flow can produce variable detection rates among years or within a migration season.

Table 5: Detection history (number of juvenile Coho detected/not detected at McNary and Bonneville dams) and detection rate during out-migration of smolt release groups (A) and parr release groups (B) over migration years 2015-2020. Enumeration of fish fate (Release/detection histories) is coded by detection (1) and no detection (0) such that "1.0.0." = no juvenile detection after release, "1.0.1" = not detected at McNary Dam but detected at Bonneville Dam, "1.1.0" = detected at McNary Dam but not at Bonneville Dam, and "1.1.1" = detected at both dams.
A. Smolt releases

| Detection History | 2015 | 2016 | 2017 | 2018 | 2019 | 2020 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| No detection after release (1.0.0) | 18167 | 23128 | 13601 | 18356 | 19775 | 12430 |
| Detected at BON Dam but not at McNary Dam (1.0.1) | 392 | 621 | 337 | 483 | 338 | 1153 |
| Detected at McNary Dam but not at BON Dam (1.1.0) | 179 | 825 | 431 | 379 | 168 | 230 |
| Detected at all Dams (1.1.1) | 55 | 203 | 43 | 48 | 24 | 52 |
| Detection rate (\%) | 12.30 | 24.63 | 11.31 | 9.03 | 6.23 | 4.31 |
| Standard Error ( $\pm$ SE) | 1.51 | 1.51 | 1.62 | 1.24 | 1.31 | 0.58 |

B. Parr releases (released parr typically outmigrate as yearling smolts). The year is the migration year. For example, number of fish in 2015 is the number of parr released in 2014.

| Detection History | 2015 | 2016 | 2017 | 2018 | 2019 | 2020 |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| No detection after release (1.0.0) | 28547 | 25473 | 20614 | 41175 | 1283 |  |
| Detected at BON Dam but not at | 19 | 41 | 333 | 30 | 4 |  |
| McNary Dam (1.0.1) |  |  |  |  |  |  |
| Detected at McNary Dam but not <br> at BON Dam (1.1.0) | 41 | 283 | 260 | 69 | 4 |  |
| Detected at all Dams (1.1.1) | 4 | 18 | 37 | 1 | 1 |  |
| Detection Rate | 0.90 | 3.82 | 13.98 | 5.26 | 25.0 |  |
| Standard error ( $\pm$ SE) | 0.39 | 0.74 | 2.05 | 5.13 | 21.65 |  |

Note: there was no parr release in 2016 (migration year 2017)

### 3.4 Survival Probability (Release Site to McNary Dam)

## A. Survival probability of smolt and parr releases by migration year

The average survival probability of juvenile Coho smolts from tagging to McNary Dam in 2020 was $47.14 \pm 5.78 \%$, which was higher than the averages in the previous 5 years (Figure 2). Obtaining the higher survival rate for 2020 migration can be due to an effect of release location because more than $90 \%$ of the smolts in 2020 were released from Prosser Dam compared to all other years: when smolts were released from several other locations in the Yakima Basin, all upstream from Prosser Dam. The previous studies showed that the survival rates were lower for the groups released from other locations compared to the group released at Prosser Dam. Outmigration survival rates might have been also influenced by in-river conditions such as water temperature and river flow in addition to outmigration distance as reported by Scheuerell et al. (2009), Petrosky and Schaller (2010) and Haeseker et al. (2012). For example, in 2015 there was an extremely low snow pack and an early snowmelt, which would have affected flow rate and water temperature. Not only for Coho, Summer chinook had also higher survival rate in 2020 compared to previous years. So other important environmental variables not included in the study may have a positive effect on the survival rate during the 2020 migration year.

The higher survival rate in the 2020 migration year can be also associated with either early fish release timing or favorable river flow or a combination of both. In 2020, the majority of the fish were released in the early period (end of the March), whereas in 2019 they were released in the middle period (April-May, Figure 7, Table 11). Since these fish were released early they were exposed to more pulse flow events (reservoir releases specifically for fish outmigration, Figure 9), compared to number of such events in 2019, which might have facilitated their migration down the Yakima River. Previous results in the Yakima Basin have shown that juvenile downstream survival increases as river flow increases, similar to the results cited above. Although releases from Prosser are advantageous from the standpoint of juvenile survival, adult harvest augmentation and assuring sufficient number of local broodstock for future juvenile releases, upstream releases are more likely to result in adult homing to viable spawning and rearing habitat and the ultimate development of self-sustaining natural coho populations in the Yakima Basin.

For the 2019 parr release migrating in 2020, very few PIT-tagged fish were detected downstream from McNary Dam, and consequently the survival rate was very low. In previous years, despite being
lower, survival rates of parr releases varied from year to year in a similar manner to those of smolt releases (Figure 2).

Because of their known effects on survival from other studies, river flow and release month were introduced as covariates in the CJS model using PIT-tag data from 2015-2020 releases as mentioned in methodology. The results also showed that effect of river flows on outmigration survival rate depend on the release months (February, March and April). Coho smolts released in March had a higher survival rate compared to February and April releases.

The only lower Yakima Basin parr releases were in Ahtanum Creek in 2019 but survival rate for Ahtanum Creek was very low. Pooling all other parr releases over the migration years 2015-2020, comparisons could be made among the parr release months of May through October. Release site-to-McNary survival of the parr-releases was highest for the population released in August $(14 \% \pm 0.020)$, followed by the groups of released in July ( $3.1 \% \pm 0.40$ ) and June ( $1 \% \pm 0.4$ ).

Figure 2. Overall smolt survival rate ( $\pm$ SE) from release site to McNary Dam for smolt and parr releases in migration years 2015-2020. The asterisk for 2020 indicates that the survival rate of parr could not be estimated because of no detection at dams below McNary Dam.

## B. Survival probability of smolt releases by broodstock

During the 2020 migration year, the survival rate was higher for the Eagle Creek-stock releases (52.6 $\pm 7.4 \%$ ) than for the Yakima Basin- stock release ( $41.1 \pm 10.1 \%$ ). In 2019 and 2020, there was no release of the Washougal stock. However, when we estimated the survival rate by pooling the data for 6 years from 2015 to 2020 by stocks (Yakima-stock releases and out-of-basin Eagle Creek-stock and Washougal-stock), we found that the average survival rate (2015-2020) for smolt releases differed among the stocks (Figure 3). The highest survival rate was for Eagle Creek smolts and the lowest was for Washougal smolts.

Figure 3. Average Coho smolt survival rate (release to McNary Dam) and $95 \%$ confidence intervals by broodstock origion for the migration years 2015 through 2020.

We had an expectation that survival rate of the smolts of the in-basin broodstock (Yakima broodstock) should have higher survival rate compared to Eagle Creek outplants, but that was not the case. We further evaluated whether there was an effect of hatchery environment on the survival rate. We were able to compare hatchery environments with two Stiles Pond releases in 2016 that varied only with respect to hatchery environment. Both were Yakima stock but one was reared at Prosser Hatchery and the other at Eagle Creek Hatchery: tag file session notes read: "Yakima coho smolts reared at Prosser and released from Stiles pond" and "Yakima coho smolts reared at eagle cr NFH and
released from Stiles pond". The survival rate from Stiles Pond to McNary Dam was higher for the smolts reared in Eagle Creek Hatchery ( $35.26 \pm 4.14 \%$, mean $\pm$ SE) than for those reared in Prosser hatchery $(13.28 \pm 1.49 \%$, mean $\pm$ SE). This variation in the survival rate indicates that hatchery environment seemed to have an effect. Variation in survival rate among hatcheries can be associated with many factors including water temperature and water quality of the hatchery. Previous studies outside of the Yakima basin showed that the size of the fish also affected the juvenile survival rate but we did not measure whether fish sizes of the smolts reared in two different hatcheries were different.

## C. Survival probability of smolt and parr releases by release location

## C. 1 Smolt releases

In each year, smolts released at the Prosser site had the highest survival among all Yakima River sites (Table 6). Annual survival rates during 2015-2020 for all sites ranged from a low of $0.88 \pm 0.6 \%$ in 2019 (Ahtanum Creek) to a high of $97.8 \%$ in 2018 for the Prosser release (Table 6, Figure 4). The high survival estimates for 2018 may be due to low estimated detection efficiencies for that release group, and this estimate was also based on the different method (see Neeley 2018) than the CJS model. For 2019 and 2020, we employed CJS models, which have been commonly used within the Federal Columbia River Power System (FCRPS) to estimate survival rates for juvenile anadromous fish species (Tuomikoski et al. 2013). In 2020 the Prosser release group had a $41.1 \%$ survival rate to McNary Dam. The survival rate of the smolts released into Ahtanum Creek could not be estimated because none of the Ahtanum tags were detected at McNary Dam (Table 6, Figure 4).

Table 6. Survival probability from the release location to McNary Dam for Coho smolt releases from 2015 through 2020. For 2019 and 2020 results, standard errors are also given (mean $\pm$ SE). "NA" means that survival rate could not be estimated because there were not enough detections at downstream dams.

| Stock | Release site | 2015 | 2016 | 2017 | 2018 | 2019 | 2020 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

Figure 4. Survival probability (release site to McNary Dam) of Coho released as smolts in outmigration years 2019 and 2020.

## C.1.1. Annual comparison of survival rates for Prosser releases

As shown above, the juvenile outmigration survival rate to McNary Dam varied by release locations. Prosser releases had the highest survival rates among the groups released from the different locations, but it also varied among years. The highest estimated survival rate for a Prosser release was $97.9 \%$ in 2018 (Table 7), but as discussed above, the estimate is likely to be inaccurate, either because of a low detection rate at downstream dams or methodological errors. Ignoring 2018, the highest survival rate was in 2014 ( $78 \%$ ) and the lowest was in 2016 ( $22.9 \%$, Table 7).

Table 7. Survival to McNary Dam for Yakima-origin Coho released at the Prosser site. Standard errors are available only for the 2019 and 2020 releases.

| Year | Number released | Release Date | Travel days <br> (Mean $\pm$ SE) | Survival Probability <br> $($ Mean $\pm$ SE) |

Note: Estimates for the years prior to 2019 were adopted from Neeley (2018)

## C.1.2. Annual comparison of survival rates for Stiles releases

Similar to Prosser, the survival rate to McNary dam of Stiles releases also varied by year. There were no Stiles releases in 2018, 2019 or 2020 (Table 8).

Table. 8. Survival to McNary Dam for Yakima-origin released from Stiles Pond.

| Year | Number released | Release Date | Travel days <br> (Mean $\pm$ SE) | Survival Probability <br> (Mean $\pm$ SE) |
| :---: | :---: | :---: | :---: | :---: |

| 2016 | 3768 | $4 / 7$ |  |  |
| 2017 | 5007 | $4 / 17$ |  |  |
| 2018 | NO RELEASE |  |  |  |
| 2019 | NO RELEASE |  |  |  |
| 2020 | NO RELEASE |  |  |  |
| Re |  |  |  |  |

Note: Results were adopted from Neeley (2018)

Although the survival rates of Prosser and Stiles releases both varied by year, the Prosser release groups had higher survival rates to McNary Dam in most years than the Stiles groups. Only in 2012 and 2016 did Stiles releases survive better than Prosser releases (Figure 5).

Figure 5. Bar plot showing survival to McNary Dam for the Yakima-origin Coho released at Prosser Dam from 2007 through 2020 (red color) and from Stiles Pond (green color) from 2001 through 2020. The 2019 and 2020 results included $95 \%$ confidence intervals).

## C. 2 Parr releases

For the migration year 2020, the survival rate for the Coho group released as parr in 2019 from the release site to McNary Dam was very low. Fewer tags were released in 2019 than the average for prior parr releases ( 3000 tags is a typical release, but 2019 release was under 1300 tags), and small sample sizes may have combined with poor survival. Previous years' results have shown marked fluctuations in survival of parr releases (Table 9), and the survival rates for parr releases in the Yakima basin have been generally lower than the survival rates from smolt releases. For migration year 2019, the survival rate of parr releases was $\sim 5 \%$ (Figure 6), with the highest survival rate observed among releases from the Rattlesnake Creek and the lowest measurable survival rate for the Big Creek and South Fork Cowiche Creek groups (less than 1\%; Table 9). Survival rate from Swauk Creek to McNary Dam was also low ( $0.13 \%$ ) but its standard error was very high ( $75.53 \%$ ), because
only a few fish were detected at downstream dams (Table 9, Figure 6). Releasing more PIT tags per release site would help to reduce the error rates.

Table 9. Survival probability (from the release location to McNary Dam) for Coho parr releases in 2018 and 2019 (outmigration years 2019 and 2020). "NA" or "*" represent releases with too few downstream detections to estimate survival rate or to reduce estimation error.

| Release Location | 2019 |  | 2020 |  |
| :---: | :---: | :---: | :---: | :---: |
|  | Mean (\%) | SE (\%) | Mean (\%) | SE (\%) |
| Ahtanum Creek | 4.71 | 1.06 |  |  |
| Rattlesnake Creek | 15.25 | 5.07 |  |  |

| Tieton River | 9.16 | 8.6 | 0.93 | 0.71 |
| Coleman Creek | 4.79 | 2.92 |  |  |
| Little Naches | NA |  |  |  |
| Wilson Creek | 2.14 | 0.87 |  |  |
| Yakima River (Thorp <br> Boat Ramp) | NA |  |  |  |
| All (Pooled) | 5.26 | 5.31 |  |  |

* There was an issue in model convergence because of low or no detections at downstream dams

Figure 6. Survival probability from release site to McNary Dam of the group released as parr in migration years 2019 and 2020 (release year 2018 and 2019). "NA" indicates no estimate of the survival rate due to lack of model convergence (not enough detections at downstream dams).

## C.2.1. Annual comparison of survival rates for parr releases in Yakima Basin streams

Table 10 summarizes annual variations in survival rates of Coho parr released from seven locations in the Yakima Basin. There was substantial variation among years within sites, and among sites within years.

Table 10. Estimated survival from release to McNary Dam of Coho released as parr, by release location and migration year. For 2019 and 2020 results, average survival rate and its standard errors are also given (mean $\pm \mathrm{SE}$ ) where applicable. An asterisk indicates that the survival rate could not be computed because of too few downstream detections.

| Released river/ tributary | Year | Released <br> $\operatorname{Pop}^{n}(\mathrm{~N})$ | Survival rate (\%) | SE | Stock | Notes |

C.2.2. Effect of release month on parr survival rate

Parr were released at different locations from May to October (Table 11, Figure 7). Survival from release to downstream detection at McNary Dam (outmigration years 2015-2020) was highest among parr released in August ( $14 \% \pm 0.020$ ), followed by parr releases in July $(3.1 \% \pm 0.40)$ and June ( $1 \% \pm 0.4$ ). Lower survival rates for groups released in May and June are likely due to mortality associated with longer exposure to summer conditions. Water temperature increases in most river sections during summer while parr are rearing. In the summer time, coho salmon fry reportedly
prefer water temperatures of $50^{\circ} \mathrm{F}$ to $59^{\circ} \mathrm{F}\left(10^{\circ} \mathrm{C}\right.$ to $15^{\circ} \mathrm{C}$; Reiser and Bjornn 1979), while higher temperatures may cause greater mortality in the parr life stage.

Table 11. Total number of PIT-tagged parr released by month from all locations in the Yakima Basin, and survival rate to McNary Dam for each month for pooled migration years 2015-2020.

Figure 7. Survival probability (release location-downstream to McNary Dam) of parr released in different months. The relationship was built using tag detections in the last five migration years (2015-2020).

## C. 3 Effect of river flow and release month on survival rate

One of our monitoring objectives was to evaluate the effects of river flow on outmigration survival rate, and to determine whether the effect differed as a function of smolt release month (February, March and April). Data showed that the average river flow measured below Prosser Dam during April, May and June of 2020 was approximately 2050, 2107 and 1241 cubic feet per second (cfs), respectively, which were higher than the average flow in April, May and June of 2015 but slightly lower than the average April flows for 2016 through 2019 (Figure 8, Table 12). However, river flow in June 2020 was higher than in previous years with the exception of 2017. River flow for the period from June through September in all years was considerably lower than in April and May, which is typical for Western rivers. Summer flow below Prosser Dam is maintained by reservoir releases to protect aquatic life, but target flows can vary according to how much water remains in storage.

Table 12. Average monthly Yakima River flow (cfs) measured below Prosser Dam (gaging station YRPW).

| Year | Months |  |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| 2015 | 4793 | 4420 | 2523 | 1043 | 895 | 420 | 387 | 526 | 581 | 892 | 3549 | 5237 |
| 2016 | 2632 | 8603 | 7982 | 8600 | 3437 | 983 | 822 | 519 | 517 | 2086 | 2582 | 1920 |
| 2017 | 1696 | 3460 | 9492 | 8778 | 6959 | 2697 | 640 | 666 | 657 | 1463 | 3585 | 2434 |
| 2018 | 3038 | 4138 | 2632 | 5183 | 6183 | 994 | 574 | 604 | 542 | 1054 | 1489 | 1775 |
| 2019 | 1389 | 1536 | 3066 | 4444 | 1860 | 563 | 560 | 749 | 568 | 1041 | 1458 | 2122 |
| 2020 | 3145 | 4411 | 1470 | 2050 | 2107 | 1241 | 577 | 584 | 693 | 1407 | 2195 | 2120 |

Figure 8. Average daily Yakima River flow (cfs; blue line) and 20-day average flow (smoothed yellow line) measured near Prosser Dam from January to December (2015-2020). The boxes (red border) highlight the time period when Coho smolts were released from different locations.

A CJS model was used to evaluate the effect of river flows on outmigration survival rate for each release month (February, March and April). Among several candidate models considered, the model with river flow and release month was the most parsimonious; the best competing model was $\varphi$ ( $\sim$ Dam:Year:month + RF) p $(\sim$ Dam:Year:month + RF $)$. Based on the best CJS models that included river flow and release months as covariates (the model with the lowest QAICs), we observed a positive correlation between flow and survival rate (survival increased as flow increased) for all three months. The highest survival rates over the range of flows were found for the March release groups,
followed by April releases, and lastly February releases (Figure 9). Since Prosser was the only location with releases in each month, we could not compare the effect of release time (months) for all release groups across all locations. Survival rates among years at the Prosser location (See Figure 9) were highest for the March release groups. However, the sample size for February releases was comparatively small ( $4 \%$ of total releases) compared to March releases ( $45 \%$ ) and April releases (51\%).

Figure 9. The relationship between survival probability from release location to McNary Dam and the river flow at Prosser Dam for the smolt release groups each month. The relationship was devolved using the 6 years of PIT-tag data (2015-2020).

### 3.5 The Smolt-to-Adult Returns (McNary juvenile to Bonneville adult)

The SAR estimates varied by year and life stage at release (parr and smolt) during the study period (Table 13, Figure 10). On an average, the SAR was slightly higher for the group released as parr (SAR: $3.98 \pm 1.06 \%$ ) compared to the SAR of the group released as smolts (SAR: $3.79 \pm 1.06 \%$ ). The highest SAR for the group released as parr was in 2018 ( $8.75 \% \pm 1.66 \%$ ), followed by the groups released in 2013 and 2008, and lowest was in 2006 ( $0 \%$ ). For smolts, the highest SAR was for the group released in 2008 ( $8.28 \pm 0.25 \%$ ) and followed by 2013 ( $8.08 \pm 0.91 \%$ ), 2010 ( $6.48 \pm 1.14 \%$ ), and the lowest was in $2011(0.85 \pm 0.25 \%)$. The variation in SARs among years can be associated with many factors such as smolt size, release and ocean entry timing, and ocean conditions.

Table 13. Smolt-adult returns (SAR, based on juvenile detection at McNary Dam and adult detection at Bonneville Dam) for each release over migration years 2004-2020. The values with yellow color indicates the value is subject to revision if 3-ocean adults may return in 2021 from the 2018/2019 releases. "N" represents the number of fish with PIT tags released; "SE" is the standard error.

Figure 10. Smolt-Adult-Return (SAR) of coho (Hatchery) for the group released as parr and smolts from 2004 to 2019 in Yakima Basin based on juveniles detected at McNary Dam (downstream migration) and the subsequently detected as returning adults at Bonneville Dam. The SAR value for outmigration year 2019 is subject to revision if 3-ocean adults return in 2021 from the 2019 migration year.

### 3.6 Age- distribution at return

From outmigration year 2004 through 2019, a total of 3194 returning Coho with PIT tags that were released as smolt and 1459 returning Coho that were released as parr in the Yakima Basin were detected at Bonneville Dam. Among the tagged adults released as smolts, $\sim 85 \%$ of the returning coho were age 3 (ocean age 1) while $9 \%$ of the returns were age 2 (year ocean age 0 ), and $7 \%$ were age 4 (ocean age 2). For the group released as Parr, $90 \%$ of retuning coho were the age $3,10 \%$ of the returns were the age 2 , and no returns were age of 4 .

Table 14. Total number of PIT-tagged Coho detected at return to Bonneville Dam by ocean age (years) for the group of fish released as a life stage "smolt" (A) and the group of fish released as "Parr" (B). Values shaded yellow are subject to change based on any 3-ocean returns.

## 4. Acknowledgment

We thank all of the crews whose collective fish-tagging efforts over the years made this study possible. We are also grateful to David Lind, who provided valuable comments in the draft report. We would also like to thank Daylen Isaac, who provided the hydrological data.

## Executive Summary

Summer-run Chinook salmon were once widely distributed in the Yakima River basin but were extirpated by the 1970s. Since 2009, building on habitat, passage and instream flow restoration efforts, the Yakama Nation has been implementing a reintroduction program, in which summer chinook eggs are brought from Upper Columbia Basin hatcheries to the Yakama Nation's Marion Drain Hatchery for fertilization, incubation and rearing. Subyearling/presmolts are moved from the hatchery to permanent and mobile acclimation sites upriver for release as smolts into different areas of the Yakima basin. Diverse release strategies, such as releasing from different locations and experimenting with different release dates, have been utilized to maximize the likelihood of achieving stable and abundant returns of natural-origin summer Chinook to the Yakima River basin and to enhance the stability and resiliency of the population against potential environmental changes.

In 2020 a total of 768,378 subyearling summer Chinook were released, with 12,814 (about $1.67 \%$ of the total release and relatively low in comparison to the previous years because of COVID-19 pandemic restriction) tagged for monitoring purposes, especially to evaluate juvenile survival rates and release strategies. This evaluation is an update of ongoing annual monitoring that was initiated with the first reintroductions in 2009. The main objectives of the study are to estimate survival rate of the fish released from each location in the Yakima Basin in 2020 and compare the results with previous years' results to evaluate success and discern trends. We further evaluate whether juvenile survival rate varies significantly among release locations whether the survival rate is a function of release location, release year and month, river flow and size of released fish. For data collected in prior years (2009 through 2018), a logistic regression model (Neeley 2012) was used to estimate survival probability. Since 2019, survival probability from the release locations to downstream dams and detection rate at Prosser and McNary Dams have been estimated using the Cormack-Jolly-Seber (CJS) mark-recapture model, along with other statistical analysis of travel time and the effect of river flow to answer the following research questions:

## - What was the detection rate of juvenile summer chinook at Prosser Dam and McNary Dam, and do the detection rates vary by year? If there is an annual variation in the rate of detection, what factors cause this variability?

The average rate of detection at McNary Dam for the 2020 PIT-tag release was found to be $7.91 \%$ ( $\pm 1.51 \%$, mean $\pm$ SE); whereas the detection for the fish at Prosser Dam was $27.02 \%$ ( $\pm 3.65 \%$ ). Over the years 2009-2020, detection rate varied at both dams, and was lowest in 2015, due to poor river conditions in that year. Annual variation can be due to many factors besides river conditions, such as what proportion of fish pass dams via juvenile bypass systems where detectors are installed. As spill has been increased to improve survival of juvenile fish passing dams within the Federal Columbia River Power System, a lower proportion of outmigrants enter juvenile bypass systems where PIT tags can be detected, and variations in spill percentage can make the detection rate vary among years or even from day to day.

## - What was the juvenile survival rate to McNary Dam of each of the groups released to different streams in the Yakima Basin during 2020?

In 2020, the overall juvenile outmigration survival rates from the release site to Prosser Dam and from Prosser to McNary Dam were $43.7 \% \pm 4.0$ and $33.6 \% \pm 6.3$, respectively. When the survival rate of both segments was combined, survival rate of the summer Chinook in 2020 from the release site to McNary was $14.7 \% \pm 2.5 \%$., which is double of the survival in the 2019 migration year ( $7.2 \% \pm 1.1$ ). The higher survival rate in 2020 migration year might be associated with the early fish release timing and favorable river flow. In 2020, the majority of the fish were released in early (April 10 and May 8), whereas in 2019 they were released in mid-period (May 13, May 17, May 19 and May 20). Earlier releases in 2020 were exposed to more pulse flow events (five events), which might have facilitated their outmigration and increased their survival rate. Previous results have shown that juvenile downstream survival increases as river flow or pulse flow events increase.

Fish were released at three locations (Buckskin, Roza and Prosser) in 2020; but the 2019 release from Wapatox was not repeated in 2020 because of poor 2019 survival related to canal flow. Similar to the previous years, 2020 survival rates varied somewhat among release locations. Survival rate from the release location to Prosser Dam of the group released in Buckskin and Roza during 2020 were found to be $40.9 \% \pm 3.6 \%$ and $40.3 \% \pm 3.3 \%$, respectively. From release location to McNary Dam, survival rates were $13.6 \% \pm 3.4 \%$ for the group released in Buckskin, $15 \% \pm 5.6 \%$ for Roza; and $16.9 \% \pm 5.6 \%$ for the below-Prosser release group.

## - What was the overall temporal pattern of survival rates for summer Chinook during the

## study period (from 2009 through 2020), and among the groups released in different locations?

Survival rates varied by year over the period from 2009 through 2020, reflecting interannual variation in river flow, dam operations and environmental conditions such as water temperature that affect salmon during the critical juvenile life stage. The highest average annual survival rate from the release points to McNary Dam was in 2011 ( $40.15 \% \pm 1.94 \%$ ) and the lowest was in 2015 $(0.73 \% \pm 0.47 \%)$. In general, the survival rate was found to be high when were fish released early (April) as well as when river flow was high or there were more pulse flow events during the outmigration period. The relationship between the average of monthly river flow for May and June (measured below Prosser Dam) and the annual survival rate (release location to McNary Dam) from 2009 through 2020 was strong and statistically significant $\left(\mathrm{r}^{2}=0.54, \mathrm{p}=0.01\right)$, indicating that survival rate was a function of river flow in May and June.

Overall survival rates for the period 2009 through 2020 varied among release locations as well. The highest survival rate from release to McNary Dam was for the group released from Stiles Pond ( $20.3 \% \pm 11.03 \%$ ) and the second highest survival rate was for the Buckskin Slough group ( $19.2 \%$ $\pm 6.81 \%)$. The lowest survival rate was for the group released from Wapatox Dam ( $0.15 \% \pm 0.14 \%$ ) in 2019.

## - With smolts released in different months (April, May and June) to increase temporal distribution, was fish size different for different release dates? What was the effect of fish size and release month on survival rate from the release sites to Prosser Dam, and from Prosser Dam to McNary Dam?

There was an effect of release period (April, May or June) and fish size (fork length) on the juvenile survival rate for both segments (release site to Prosser Dam; and Prosser Dam to McNary Dam). For example, in an average if the fish size with 50 mm released in April, its survival rate from the release location (it can either Buckskin or Roza) to Prosser was estimated to be above $50 \%$; whereas for the same size of fish released in June, the survival rate to Prosser Dam was estimated to be about $10 \%$. From Prosser to McNary Dam, the relationship of size to survival rate was similar for April and May releases, but release in June depressed the Prosser-to-McNary survival rate over the entire range of fish sizes.

- Did fish released earlier (April) enter the Columbia River estuary earlier (based on detections at Bonneville Dam) than fish released later (June), or did earlier outmigrants travel slower in order to prepare physiologically for saltwater, so that all groups entered the estuary near the same time regardless of when they were released?

The summer Chinook releases generally exhibited immediate outmigration behavior after release, regardless of release date, but later outmigrants showed greater urgency. Travel days from Prosser Dam to Bonneville Dam for the groups released in April were $73.08 \pm 37.77$ days, whereas the fish released in June took only $32.70 \pm 9.89$ days to reach Bonneville Dam.

- What was the rate of rate of travel from Prosser Dam to Bonneville Dam of the groups released in April, May and June?

The rate of travel to Bonneville Dam was $7.19 \mathrm{~km} /$ day for the group released in April, but the rate of travel more than doubled ( $16.64 \mathrm{~km} /$ day $)$ for the group released in June. This indicates that fish released earlier spent more time in the mainstem in order to go through the series of physiological and morphological changes that allow for a transition to life in salt water. The study suggests that regardless of when they were released, the summer Chinook seemed to enter the ocean at nearly the same time, although outmigration survival rate was higher for the early release.

- What was the Smolt-Adult-return (SAR) of the group released each year and from each location during the study period (2009-2020)?

SAR is the percentage of smolts that survive and return to spawn and is the metric that captures most of the cumulative impacts of the hydrosystem and ocean condition on fish, indicating the sustainability of adult returns over time. In this study, SARs were based on the percentage of smolts detected at Bonneville Dam that returned as adults to Bonneville Dam. Since summer Chinook can spend as many as 5 years in the ocean, we estimated SAR of the populations that out-migrated from 2009 through 2017. The SAR estimates varied by year during the study period. The highest SAR was for fish released in 2011 ( $10.24 \pm 1.14 \%$ ) and $2012(4.24 \pm 0.09 \%)$, whereas it was zero for the group released in the drought year of 2015. For the group of fish released in other years had about $1 \%$ SAR (Bonneville to Bonneville). The variation in SARs among years can be associated with many factors such as smolt size, release and ocean entry timing and ocean conditions.

- What was the age composition of the adult returns?

From the total of 1104 returning adult fish with PIT tags were detected at Bonneville Dam from 2009 through 2017, $64 \%$ were age 4 (3-year ocean age), $23 \%$ of the returns were age 3 ( 2 - ocean), $9 \%$ were age 5 (4- ocean) and less than $1 \%$ were age of 6 ( 5 -year ocean age). Four percent of the juveniles detected at Bonneville returned as jacks (age-2, 1-ocean).

## 1. Introduction

The summer Chinook (Oncorbyncbus tshanytscha) is one of the three historical chinook runs in the Yakima River basin. Adults of the summer run first enter the Yakima River from the ocean in June, and the remainder of the summer run is shaped by flow and temperature in the lower Yakima River, which is strongly influenced by irrigation withdrawals and return flow. Unfavorable conditions can delay entry of the latter part of the summer run from the Columbia River until near the fall spawning season. Juvenile summer Chinook typically leave the Yakima River from late spring to early summer of the year after spawning. Summer Chinook were once widely distributed in the Yakima and Naches rivers (Figure 1) but were extirpated from the Yakima basin by 1970. For decades, several programs such as habitat restoration and species reintroduction were implemented in the Yakima River. With improving spawning and rearing habitat conditions made possible by habitat and instream flow restoration, with improved juvenile and adult passage in the mainstem Columbia River, and with improved ocean conditions, reintroduced adult summer chinook, along with supplemented fall chinook, are returning to the Yakima basin. Annual abundance of summer/fall Chinook at Prosser Dam on the lower Yakima River has increased from an average of just over 1000 fish from 1983 through 1999 to over 4,300 fish on average during the period 20002018). We have successfully achieved some level of natural production and local adaptation, however it is still unstable.

Based on 2009-2020 release data, an annual average of 282,775 summer Chinook juveniles were released in the Yakima basin (Table 1). Usually each year, eggs of the species are brought either from the Entiat or Wells hatchery (Entiat and Wells stocks) to the Yakama Nation's Prosser Hatchery for fertilization, incubation and rearing through the fall and winter. The following spring, subyearlings are moved to the acclimation sites upriver and are released directly from permanent acclimation sites on the Yakima and Naches rivers or from temporary mobile acclimation facilities operated on smaller tributary streams. Several release strategies have been utilized to maximize the likelihood of achieving stable and abundant returns of the species to the Yakima River and to enhance the stability and resiliency of the population against potential environmental changes. The strategies include releasing the juveniles into different tributaries (spatial variation) and also different dates (temporal variation). Whether one release strategy performs better than other strategies in terms of juvenile survival and smolt-to-adult return (SAR) are fundamental questions in determining whether
species management and production goals are being reached. On average each year about $12 \%$ of the total release is PIT-tagged as part of an ongoing, long-term monitoring program to refine project objectives and strategies, applying what is learned from experimentation, monitoring, evaluation and literature reviews as an adaptive management framework. This evaluation is an update of ongoing annual monitoring that began with the first reintroductions in 2009.

Juvenile survival rates often vary by seasons and years. This variation can be associated with rearing history and environmental conditions. For example, Zabel and Achord (2004) found that juvenile survival rate of wild salmonids was related to fish size (fork length), with larger juveniles having higher downstream survival. Survival rate also increases as river flow increases. Although the Yakima River is highly controlled by storage reservoirs and irrigation and hydropower withdrawals, there is still a large variation in the flow pattern within and across years, which can affect the survival rate of juvenile salmon. Ocean-type summer and fall chinook, which naturally outmigrate from Columbia River tributaries in late spring and early summer, can be harmed by rising water temperature as they attempt to leave the Yakima Basin. Based on the effect of temperature, one can postulate that survival rate should be lower if the fish are released in later months, e.g. June, than fish released as early as April. However, individuals released earlier are likely to be smaller than fish released later and closer to natural outmigration timing. There may be an interaction between fish size and release timing on survival.

The primary objectives of the study are to explore the effect of release date and fish size on survival. More specifically, our objectives are to determine the survival rate from release sites to Prosser Dam or McNary Dam of groups released at different locations in the Yakima Basin during 2020; and understand how other factors (fish size and release date) affect juvenile survival rates using the last 11 years' data (2009-2020). This information is critical for recovery of depressed Chinook stocks.

To achieve these objectives, we focused on the following research questions:

- What was the detection rate of juvenile summer chinook at Prosser Dam and McNary Dam, and do the detection rates vary by year? If there is an annual variation in the rate of detection, what factors cause this variability?
- What was the juvenile survival rate from the release sites to McNary Dam of each of the groups released to different streams during 2020?
- What was the overall temporal pattern of summer Chinook survival rate during the study
period (from 2009 through 2020), and among the groups released in different locations?
- With smolts released in different months (April, May and June) to increase temporal distribution, was fish size different for different release dates? What was the effect of fish size and release month on survival rate from the release sites to Prosser Dam, and from Prosser Dam to McNary Dam?
- What was the rate of rate of travel from Prosser Dam to Bonneville Dam of the groups released in April, May and June?
- Did fish released earlier (April) enter the Columbia River estuary earlier (based on detections at Bonneville Dam) than fish released later (June), or did earlier outmigrants travel slower in order to prepare physiologically for saltwater, so that all groups entered the estuary near the same time regardless of when they were released?
- What was the Smolt-Adult-return (SAR) of the group released in each year (each migration year) and the different locations during the study period (2009-2020)?
- What was the age composition of the adult returns?

## 2. Methodology

### 2.1. Geographical distribution: historical and current

Chinook (spring, summer, and fall runs) were native to the Yakima River basin and their historical spawning area was quite widespread in the basin (Figure 1A) but their spawning area has been reduced (Figure 1B). A major objective of the summer-run Chinook reintroduction program, begun in 2009 , is to re-establish spawning in the primary historical spawning areas for this run, which are the Yakima River upstream of Wapato Dam through the canyon reach above Roza Dam, and the Naches River from the Yakima River to its confluence with the Tieton River (Figure 1C). The uppermost acclimation and release sites designated in the reintroduction program were located to facilitate adult homing throughout this historical geographical distribution, while the lower sites (Marion Drain downstream to the river mouth) were chosen to maximize survival rates and improve opportunities to collect returning adults as we work to establish a localized brood source (Figure 1D).

Figure 1. Historical (A) and current (B) summer Chinook spawning area; and the locations/tributaries/river segments where summer Chinook juveniles were introduced from 2009 through 2020.

### 2.2. Brood stocks and fish data

Every year, eggs of summer Chinook have been brought to Yakima basin either from the Wells Hatchery which is located in Pateros, WA (especially for the years from 2009-2020) or Entiat Hatchery (2018-2019) or Wenatchee Stock from Eastbank Hatchery (2010) (See Figure 2). The adult fish were spawned at either Wells or Entiat; green eggs and milt were transferred to the YN Prosser Hatchery for fertilization, incubation and rearing. Prior to migration year 2020, presmolt subyearling juveniles were acclimated at as many as five sites upriver (Stiles Pond, Buckskin Slough (Nelson Springs), Marion Drain Hatchery, Roza Dam and Wapatox Diversion), but for migration year 2020
all subyearling juveniles were transferred to just three locations (Buckskin Slough, Prosser Hatchery and Roza Dam). Temporary mobile acclimation facilities were used in some years in upstream tributary streams of the Naches and Yakima rivers.

On average 33,425 juvenile summer Chinook were PIT-tagged per year (the range was 49,894 in 2011 to 12,814 in 2020) prior to release from April through June (Figure 1D). In 2020, a total of 768,378 subyearling summer Chinook were released from the Buckskin, Roza acclimation sites, along with a group released directly from Prosser Hatchery, including 12,814 fish with PITtags (Table 1 and Table 2) between April $10^{\text {th }}$ and May 12 ${ }^{\text {th }}, 2020$ (Table 2). The tagging effort in 2020 compared to previous years was low due to COVID-19 pandemic restrictions.

Table 1. Annual releases of summer Chinook run with and without PIT-tags and the number and percentage of PIT tags in each release.

|  | Total Release |  |  |
| :---: | :---: | :---: | :---: |
| Year | Total release (with \& without PIT tags) | PIT-tags | PIT tag Percentage (\%) |
| 2009 | 180,911 | 30,045 | 16.61 |
| 2010 | 200,747 | 29,997 | 14.94 |
| 2011 | 215,770 | 49,893 | 23.12 |
| 2012 | 197,103 | 29,996 | 15.22 |
| 2013 | 136,563 | 40,507 | 29.66 |
| 2014 | 254,881 | 30,278 | 11.88 |
| 2015 | 277,448 | 34,457 | 12.42 |
| 2016 | 37,000 | 37,000 | 100.00 |
| 2017 | 244,499 | 34,826 | 14.24 |
| 2018 | 74,000 | 30,131 | 40.72 |
| 2019 | 806,000 | 41,143 | 5.10 |
| 2020 | 768,378 | 12,814 | 1.67 |
| Average | 282,775 | 33,425 | $12 \%$ |

All regional PIT tag detection data including release and detection history are available in the PTAGIS database maintained by the Pacific States Marine Fisheries Commission. We queried PTAGIS (https://www.ptagis.org/) in April 2021 to retrieve available PIT-tag detection information for all summer Chinook juveniles released in the Yakima Basin from migration year 2009 through 2020 (Table 2). For each fish with a PIT-tag code, we constructed a detection history: a record indicating all detection locations and whether the tagged fish was detected or not detected at each juvenile detection site, focusing on Prosser, McNary, John Day and Bonneville dams (PRO, MCJ, JDJ, B2J, BCC), and by the Estuary Towed Experimental Array (TWX).

Table 2. Brood year, broodstock, and the number of PIT-tagged subyearling summer Chinook released at the different locations and dates (Early, Mid and Late) from release years 2009 through 2020 (migration year). Fish were released during April, May and June every year. Releases on or before May 10; May 11 through May 25; and after May 25 are represented as Early, Mid and Late release periods, respectively.

Note: "WELL" represents Wells Hatchery broodstock, "WENN" represents Wenatchee stock, "WELLS/ENT" represents Wells Hatchery or from Entiat hatchery Stock.

### 2.3. Statistical analyses

### 2.3.1. Survival and Detection Probability

Juvenile survival probabilities from release locations to Prosser and/or McNary were estimated for each release group or location from migration years 2009 through 2020. We also estimated the average survival rate for each migration year regardless of release site. For releases from 2009 through 2018 a logistic regression model (Neeley 2012) was used to estimate survival. Beginning in 2019 and in this report, survival probability from release locations to downstream detection at McNary Dam; and the detection rate at Prosser and McNary dams were estimated using the Cormack-Jolly-Seber (CJS) mark-recapture model (White and Burnham 1999; Lebreton et al. 1992;

Williams et al. 2002, Conner et al. 2015), which has been commonly used within the Federal

Columbia River Power System (FCRPS) to estimate survival rates for juvenile salmon and steelhead (Tuomikoski et al. 2013). The model uses multiple detections of individually marked fish at several dams with PIT-tag detection capabilities (i.e. antenna arrays). One of the assumptions of the CJS model is that there is no immigration or emigration during capture and recapture intervals, which is valid for discrete tag groups migrating through the hydrosystem (which involves passage at several hydroelectric dams) because all fish in the tag group are moving in one direction and over a relatively short period (Conner et al. 2015). All of the assumptions of the CJS models are considered to be met.

To determine how release period (April, May or June) and fish size affect the survival rate from the release location to Prosser, and from Prosser to McNary, we introduced fish size and release period as covariates in the CJS model. This CJS model was built within RMark (Laake 2019) in R, an extension of Program MARK (White and Burnham 1999). The detailed methodology is found in Appendix F of the main report. In 2020, 12,814 tagged fish were tagged, however the first detection dates of 81 tagged fish were found to be earlier than the release date. This might have been due to some of the fish escaped early during tagging or acclimation. We excluded these 81 fish from further analysis.

### 2.3.2. Relationship between annual survival rate and river flow

Several environmental factors are known to influence downstream smolt survival, and river flow is among the most impactful (Raymond 1968; Connor et al. 2003; Tiffan et al. 2009). We therefore further evaluated whether there was a relationship between the annual survival rate and the average river flow for two summer months (May and June) measured below Prosser Dam. We chose only May and June because most of the juvenile summer Chinook were released from the end of April $\left(29^{\text {th }}\right)$ to the first week of June $\left(5^{\text {th }}\right)$ ) from 2009 through 2020 (See table 2), and they usually leave the Yakima River within 3 or 4 weeks after release. Given this timing, May and June flow can be the most influential factor for the outmigration of this run of Chinook. We downloaded river flow data for the Bureau of Reclamation gaging station (YRPW) located below Prosser Dam in the Yakima River, using the Hydromet site: https://www.usbr.gov/pn/hydromet/yakima/yakwebarcread.html, which was accessed in April 2021. A univariate linear relationship between the average survival rate of each migration year and the average river flow (May and June) of each year was built to determine whether the average annual survival rate is a function of river flow.
2.3.3. Relationship between survival rate, release time (month) and fish size

Among the available PIT-tagged fish, only a few had fish length information, so we selected only those tagged fish which had fish length information available for the analysis. Fish release dates were categorized by month. As mentioned under subheading 2.3.1, we used fish length and release month as covariates in the CJS model. Using this model, the average survival rates from release location to Prosser Dam, and from Prosser to McNary Dam were estimated for the release groups with different release months (April, May, June) and the different average fish lengths.

### 2.3.4. Travel time and rate of migration or rate of travel distance per day

Travel time was estimated as the difference between either the date of release or the date of detection at Prosser Dam (site PRO), and the date of detection at Bonneville Dam (juvenile site B2J or BCC). For fish released below Prosser Dam, we estimated travel time as the difference between the release date and the date of detection at Bonneville Dam. For fish released above Prosser Dam, travel time from Prosser to Bonneville was estimated as the difference between the date of detection at Prosser Dam and the detection date at Bonneville Dam. We estimated travel time for each of three release months (April, May and June). Migration rate or rate of travel was calculated as length of the reach of interest (km) divided by travel time in days for the group.

### 2.4.5. Smolt-to-Adult-Returns (SAR)

SAR, which is the percentage of smolts that survive and return as an adult to spawn, is a metric that captures most of the cumulative impacts of the hydro-system and ocean conditions on anadromous fish, indicating how sustainable the returns of adults are over time. The SAR was estimated as the percentage of smolts detected at Bonneville Dam returning as adults to Bonneville Dam using the following equation for each year and release group:

$$
\cup_{\text {at BON }} / J_{\text {at BON }}
$$

Where, $\mathrm{U}_{\mathrm{at} \text { BON }}$ is a total number of PIT tagged fish detected at Bonneville Dam both during outmigration as a juvenile and immigration as adults. $\mathrm{J}_{\text {at BON }}$ is the total number of fish detected at Bonneville Dam as juveniles. Because summer Chinook can spend as many as 5 years in the ocean, we estimated SAR of the populations that out-migrated from 2009 through 2017 (migration year).

The variance of SAR estimates for each category was computed by a non-parametric bootstrap resampling method (Efron and Tibshirani 1993; Manly 1997). For each sample data set (release group for each migration year), individual capture histories were resampled with replacement. One thousand bootstrap sample data sets were constructed and 1000 estimates of SAR were generated. Statistical bias was assessed as the difference between the mean of the bootstrap replicates and the point estimate derived from the original data (Efron and Tishirani, 1993). Due to the non-normal distribution of bootstrap SAR estimates, bias correction was used to construct $95 \%$ confidence intervals as suggested by Manly (1997).

### 2.4.6. Age composition of adult returns

Age composition of adult returns was estimated by the proportion of each age class of adult return detected at Bonneville Dam by each migration year.

### 3.0. Results and discussion

### 3.1. Fish length

An average 33425 PIT-tagged juvenile summer Chinook were released per year from 2009 through 2020, but only 42,868 had the size information, which was about $13 \%$ of the total of PIT-tagged fish released during the study period. Based on the available data, the average size of the fish (fork length) at the time of tagging was 71 mm (Figure 2, Table 3). However, the size of the fish of the groups released in different months (March, April and May) was found to be different. We hypothesized that fish released later would be bigger than the fish released earlier, but we found that fish released in May were bigger when tagged than the fish released in June. The average fork lengths of the groups released in April, May and June were $66.98 \pm 0.115 \mathrm{~mm}, 74.17 \pm 0.06 \mathrm{~mm}$, and $63.08 \pm 0.026 \mathrm{~mm}$ at the time of tagging, respectively. Not getting the same result as we hypothesized might be due to a number of reasons. One possible reason is that the sample sizes ( N ) were different among the groups released in different months. There was a very large number of lengths in the May release group $(38,874)$; whereas the June release group had only 1844 measured fish (Figure 2, table 3). It is likely the smaller sample size did not represent the actual range of sizes of
the fish released in June. Another reason could be differences in incubation and rearing temperature among groups from different hatcheries with different water sources.

Figure 2. Frequency (count) by fish length (fork length, mm) at the time of tagging for all releases made in April, May and June from 2009 to 2020.

Table 3. Average fish size (mm) at the time of tagging by releasing year and month (April, May, June). The number "n" represents the subset of fish with length data in the PIT Tag Information System (PTAGIS; http:/ /www.ptagis.org) database.

### 3.2. Detection Probabilities at McNary and Prosser

The rate of detection at Prosser Dam varied with diversion rate; detections in the juvenile bypass system depend on irrigation and hydropower diversions during the outmigration season. Diversion rate in turn depends on Yakima River flow, which fluctuates more than the highly-regulated Columbia River discharge. The rate of detection of juvenile summer Chinook at McNary Dam also varied among years (Table 4), but within a smaller range. Variation in the detection rate at McNary Dam might be due to how surface-passage structures are operated. As with Prosser Dam, the detection rate at Columbia River dams depends upon the proportion of fish that enter juvenile bypass systems where detectors are installed. In recent years, increasing spill and the use of surfacepassage structures (spillway weirs) at dams are a primary management strategy to increase survival of juvenile fish passing dams within the Federal Columbia River Power System. Greater use of spillways results in a lower proportion of fish entering juvenile bypass systems where PIT tags can be detected (Widener et al. 2018), and fluctuations in spill and flow can produce variable detection rates among years or within a migration season.

Table 4. Annual detection rate (in percent) at McNary Dam (and its Standard Error, SE) during the period from 2010 through 2020. Enumeration of fish fate (release/detection histories) is coded by detection (1) and no detection (0). For example, at McNary Dam: the code "1.0.0." means no juvenile detection after release, "1.0.1" means not detected at McNary Dam but detected downstream of McNary Dam, "1.1.0" means detected at McNary Dam but not downstream, and "1.1.1" means detected at both McNary Dam and downstream.

In 2020, a total 12,729 juvenile summer Chinook with PIT tags were released from the 3 locations (Buckskin Slough, Roza juvenile bypass and below Prosser Dam). The average rate of detection at McNary Dam for the 2020 release was found to be $7.91 \%$ ( $\pm 1.51 \%$ SE, see table 4), whereas the detection at Prosser was $27.02 \pm 3.75 \%$. The highest detection rate for a release group at McNary Dam was for Prosser releases ( $9.5 \pm 3.4 \%$, see table 4 ). The group released below Prosser would be expected to have low mortality from release to McNary Dam compared to the groups released upstream and considerably farther from McNary Dam. In general, travel distance is considered to be an important factor influencing survival rate. As travel distance increases, mortality also increases due to higher risk of predation and changing environmental conditions.

For all upstream release groups combined, the average (pooled) detection rate at Prosser for 2020 groups was about $27.75 \pm 3.6 \%$; whereas the average detection rate at McNary was only $7.91 \pm 1.31 \%$.

Among the release groups, the highest detection rate at Prosser was $46.0 \pm 7.0 \%$ for the group released below Roza Dam (Table 4A), whereas the detection rate of this group at McNary Dam was about $6.7 \pm 2.6 \%$ (Table 5B).

Table 5. Detection rate at Prosser (PRO) and McNary Dam (McN) for the groups of sub-yearling summer Chinook released from 2010 to 2020.

* Model convergence issue due to no downstream detections.

Note: Some of the juveniles were detected at Jobn Day Dam but not detected at BON. The number of detections attributed to Bonneville Dam (BON) includes fish that were detected either at John Day Dam (JDJ), Bonnevile Dam (B2J or BCC), or by the Estuary Towed Experimental Array (TWX).

### 3.3. Juvenile Release-McNary Survival Probability

### 3.3.1. Annual juvenile Release-McNary Survival rate and its temporal trend

The survival rate of juvenile summer Chinook from release to McNary Dam varied among years (Figure 3; Table 6). The highest average annual survival rate was in $2011(40.15 \pm 1.94 \%)$ and the lowest was in $2015(0.73 \pm 0.47 \%)$. In 2020 the average annual survival rate from all release locations to McNary Dam was $14.7 \pm 2.5 \%$, which was higher than in 2019 (7.22 $\pm 1.35$ ) and 2018's survival rate ( $2.58 \pm 0.41 \%$, Figure 3; Table 6).

Figure 3. Average annual survival rate (release to McNary Dam) of juvenile summer Chinook released from 2010 through 2020.

It is important to understand why the survival rate varied among years. The juvenile survival might have been affected by many factors such as different brood stocks, release timing or river flow and including other variables. On an average the survival rate in 2011 was high (Table 6 and Figure 3). Looking at individual groups in 2011, the highest survival rate was for the group released into Buckskin Slough on the lower Naches River, which was released before May $10^{\text {th }}$, and its brood
stock was Wenatchee (Eastbank hatchery, see Table 2). For Stiles Pond, also on the lower Naches, in 2011, the survival rate was also high even though these fish were released in the middle period (May 11 through May $25^{\text {th }}$ ). The brood stock for Stiles was from Priest Rapids Hatchery.

Despite different brood stocks, release times and release locations, both groups (Stiles and Buckskin) had relatively high survival rates in 2011 compared to other years. These results suggest that other external factors might have played a role in increasing the survival rate. We explored whether Yakima River flow below Prosser Dam had an effect on survival rate. We built the univariate relationship between the average river flow for May and June and the annual survival rate, and found that survival rate was strongly influenced by May and June average river flow $\left(\mathrm{R}^{2}=0.54, \mathrm{p}=0.01\right.$, see Figure 4). It indicates that survival rate was a function of river flow, however the river flow was able to explain only about $54 \%$ of the annual variation in survival rate. Temperature or predation or interactions between temperature and flow or other factors might also have affected the survival rate. Further investigations, especially into how release period and fish size affected survival rate, are discussed in a later section (See 3.3.4. Effect of release period and fish size on survival).

Table 6. Total released smolt population, survival rate from release locations to McNary Dam and its Standard Error (SE) and the average river flow for May and June of each year from 2010 through 2020.

| Outmigration <br> /Release Year | Smolts Released | Survival Rate (\%) |  | Average River flow <br>  <br> $(c f s) ~(M a y ~ \& ~ J u n e) ~$ |
| :---: | :---: | :---: | :---: | :---: |

| 2018 | 30028 | 2.58 | 0.41 | 4064 |
| 2019 | 41071 | 7.22 | 1.35 | 1307 |
| 2020 | 12729 | 14.70 | 2.50 | 1795 |

Figure 4. Relationship between average May-June river flow and the annual survival rate of juvenile summer Chinook from all release sites to McNary Dam for the years 2010 through 2020. Each point with error bar is the average survival rate and its $95 \%$ confidence interval (CI) for each year. The dotted line with the shaded area is the predicted linear trend (survival rate vs. river flow) and its $95 \%$ CI.

### 3.3.2. Release site -to-McNary Dam survival rate among release locations and release periods

As mentioned above, the average annual survival rate from all release sites to McNary Dam varied by year. The survival rate also varied by release location (Table 7 and Figure 5 and 6). However, when the data were pooled by release period (Early, Mid and Late), the groups released earlier had about $19.39 \pm 10.75 \%$ survival rate, whereas the mid and late releases had survival rates of $16.27 \pm 3.23 \%$ and $7.6 \pm 4.48 \%$, respectively. When releases were pooled by location (see figure 6 ), the highest survival rate was for the group released from Stiles Pond ( $20.3 \pm 11.03 \%$ ) and the second
highest survival rate was for the Buckskin Slough group ( $19.2 \pm 6.81 \%$ ). The lowest survival rate was for the group that was released from the Wapatox bypass in 2018 and 2019 ( $0.15 \pm 0.14 \%$, Figure 5). Low survival for the release was must likely due to the low flow in the bypass because the bypass was designed for a much higher flow. (The Wapatox power plant was closed in 2003, with only irrigation deliveries remaining in the Wapatox canal.) There were no releases from Wapatox in 2020 while a solution to the problem was put in place. For the 2021 release we deployed a pipe from the mobile acclimation units directly to the bypass exit pipe to the river, avoiding the slack water in front of the canal's fish screens. In 2021, we also released two raceways directly into the river near the Wapatox diversion for comparison.

Table 7. Survival rate (\%) of summer Chinook from each release site to McNary Dam from 2009 through 2020 for the 7 release sites. The survival rate and its standard Error (SE) are given for the 2019 and 2020 estimates. Early, Mid and Late releases correspond to the period through May 10; May 11 through May 25; and the period after May 25 respectively.

[^13]

Figure 5. Juvenile survival rate from release site to McNary Dam for summer Chinook groups released at different locations from 2009 through 2020.

Figure 6. Average survival rate of juvenile summer Chinook to McNary Dam by release location from 2009 through 2020. Marion Drain and the Yakima River mouth each had only one estimate so that there was no variance.
3.3.3. Comparisons of survival rates from release site to Prosser Dam and from release site to McNary Dam

Survival rates from release site to McNary in 2020 were much lower than survival from release site to Prosser. For example, the survival rate for the group released from Buckskin Slough was about $40.9 \%$ to Prosser; but from Prosser to McNary it was only $33.4 \%$; and for overall survival rate from release site-to-McNary was $13.6 \%$ (Table 8 and Figure 7). Mortality from Prosser to McNary is likely concentrated in the lower Yakima river and the delta at its confluence with the Columbia River and related to high water temperature and documented heavy predation. From the delta, fish must travel 69 river kilometers (rkm) down the Columbia River to detection facilities at McNary Dam in addition to the 76 rkm from Prosser Dam to the delta, but on the basis of Columbia River smolt survival studies it is likely that most of the observed juvenile summer Chinook mortality occurs in the Yakima River from Prosser to the delta.

Table 8. Juvenile summer Chinook survival rate from each release site to Prosser Dam, from Prosser Dam to McNary Dam, and from release site to McNary in 2019 and 2020. "N" is the number of PIT tags. In 2020, 81 Buckskin fish were found detected earlier than their release date, and were excluded from the analysis.

| Year | Release Site | N | Release site to PRO |  | PRO to McN |  | Release site to McN |  |

* Indicates the model convergence issue due to no downstream detections.

Figure 7. Juvenile summer Chinook survival rate from each release site-to-Prosser Dam, from Prosser-to-McNary Dam, and from release site-to-McNary in 2019 and 2020.

### 3.3.4. Effect of release period and fish size on survival

As mentioned in the methodology section, we built the CJS model with release period (month) and fish size as covariates using the fish size information available ( $\mathrm{N}=42,868$, see chapter 3.1, Fish Size). Figure 9 (left side) shows that release period affected juvenile survival and that for fish with fork length of 50 mm in April, the survival rate to Prosser Dam exceeded $50 \%$, whereas 50 mm fish released in June had a survival rate of approximately $10 \%$. For the largest fish, there seemed to be no effect of release timing on the survival rate.
From Prosser-to-McNary Dam (right side of Figure 9), the relationship of size to survival rate was similar for April and May releases, but release in June depressed the Prosser-to-McNary survival rate over the entire range of fish sizes. Standard errors for the groups released in April and May were found to be large, which might be due to small sample size. As mentioned in 3.1., the sample size was relatively low for the group release in April $(2,155)$ and June $(1,844)$ compared to May release $(38,874)$.

Figure 8. Effect of release period and fish size on the rate of survival from the release site to Prosser Dam, and from Prosser Dam to McNary Dam. The shaded area is the standard Error (SE).

In 2020 the overall juvenile outmigration survival rates from the release site to Prosser Dam and
from Prosser Dam to McNary Dam were $43.7 \% \pm 4.0$ and $33.6 \% \pm 6.3$, respectively, but the overall survival rate of summer Chinook in 2020 from the release site to McNary was $14.7 \% \pm 2.5 \%$, which is double what it was in the 2019 migration year $(7.2 \% \pm 1.1)$. The higher survival rate in 2020 migration year can be associated with either early fish release timing or favorable river flow or a combination of both. In 2020, the majority of the fish were released in the early period (April 10 and May 8), whereas in 2019 they were released in the middle period (May 13, May 17, May 19 and May 20, Table 2). Since these fish were released early they were exposed to 5 pulse flow events (reservoir releases specifically for fish outmigration, Figure 9), compared to 4 such events in 2019, which might have facilitated their migration down the Yakima River. Previous results have shown that juvenile downstream survival increases as river flow increases.

Figure 9. Daily river flow and water temperature during the summer chinook outmigration period (March -July) and release window for 2019 and 2020.

### 3.4. Travel time or rate of migration

Summer Chinook generally exhibited immediate outmigration behavior after release, regardless of release date, but later outmigrants showed greater urgency. Travel times from Prosser Dam to

Bonneville Dam for the groups released in April were about $73.08 \pm 37.77$ days, whereas the fish released in June took only $32.70 \pm 9.89$ days to reach Bonneville Dam (Table 9).

Table 9. Travel days $\pm$ SE and rate of travel ( $\mathrm{km} /$ day $\pm \mathrm{SE}$ ) from Prosser to Bonneville Dam for the groups released in April, May and June from 2010 through 2020.

| Release <br> Month | Number of <br> PIT Tags | Travel days |  | Rate of migration <br> $(\mathrm{km} /$ day $)$ |
| :---: | :---: | :---: | :---: | :---: |
| April | 24,555 | $73.08 \pm 37.77$ |  | $7.19 \pm 0.10$ |
| May | 28,318 | $65.08 \pm 14.03$ |  | $8.15 \pm 0.04$ |
| June | 20,140 | $32.70 \pm 9.89$ |  | $16.64 \pm 0.03$ |

The distance between Prosser Dam and Bonneville Dam is normally given as 381 rkm and the rate of travel over that distance was $7.19 \mathrm{~km} /$ day for the group released in April; but the rate more than doubled ( $16.64 \mathrm{~km} /$ day) for the group released in June. The slower rate of travel for earlier releases indicates that fish released earlier spent more time in the mainstem in order to go through the series of physiological and morphological changes that allow for a transition to life in salt water. Before entering the ocean, anadromous species must change their osmoregulation process, undergoing physical adaptations of their gills and kidneys that build a tolerance to salt water. The study suggests that regardless when they were released, the summer Chinook seemed to enter the ocean at nearly the same time, although outmigration survival rate was higher for the early release.

### 3.5. Smolt-to-Adult Returns

SAR which is the percentage of smolts that survive and return to spawn and captures most of the cumulative impacts of the hydro system and ocean condition on fish, telling us how sustainable the returns of adults are over time. The SAR estimate was based on the percentage of smolts detected at Bonneville Dam that returned as adults to Bonneville Dam. In general, the SAR varied by year during the study period. The highest SAR was for the fish released in 2011 ( $10.24 \pm 1.14 \%$ ) and 2012 ( $4.24 \pm 0.09 \%$ ), whereas it was zero for the group released in 2015 (see Table 10). The groups of fish released in other years averaged about 1\% SAR from Bonneville juvenile to Bonneville adult. The variation in SAR among years can be associated with many factors such as smolt length, release timing, ocean conditions etc. Since SAR and juvenile survival both were high in 2011 and 2012 compared to other years, the higher SAR seems to be related to higher juvenile downstream survival.

Table 10. Smolt-adult returns (based on Juvenile and adult detection at Bonneville Dam) for each release over migration years 2010-2017. The value with yellow color indicates the value is subject to revision if 4-ocean adults may return in 2021 from the 2017 releases.

| Migrati on year | Stiles | Buckskin | Marion Drain | Roza | Prosser | Yakima mouth | Wapatox | Pooled |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 2010 | $1.25 \pm 0.46$ |  |  |  |  |  |  | $1.25 \pm 0.46$ |
| 2011 | $10.2 \pm 2.06$ | $10.22 \pm 1.35$ |  |  |  |  |  | $10.21 \pm 1.14$ |
| 2012 |  | $4.10 \pm 1.4$ | $3.29 \pm 1.18$ |  | $6.89 \pm 2.71$ |  |  | $4.24 \pm 0.9$ |
| 2013 |  | $2.08 \pm 0.86$ |  | $1.46 \pm 0.81$ |  |  |  | $1.80 \pm 0.60$ |
| 2014 |  | $0.69 \pm 0.6$ |  | 0 |  |  |  | $0.69 \pm 0.6$ |
| 2015 |  | 0 |  | 0 | 0 |  |  | 0 |
| 2016 |  |  |  |  | $1.07 \pm 0.48$ |  |  | $1.07 \pm 0.48$ |
| 2017 |  |  |  | $0.88 \pm 0.49$ | $1.97 \pm 1.90$ |  |  | $1.02 \pm 0.53$ |
| 2018 |  |  |  |  |  |  |  |  |
| 2019 | With incomplete returns, no SAR was calculated for 2018-2020 releases |  |  |  |  |  |  |  |
| 2020 |  |  |  |  |  |  |  |  |

### 3.6. Age-at-return distribution

From the total of 1104 returning adult fish with PIT tags were detected at Bonneville Dam from 2009 through 2017, $64 \%$ were age 4 (3-year ocean age), $23 \%$ of the returns were age 3 ( 2 - ocean), $9 \%$ were age 5 (4- ocean) and less than $1 \%$ were age of 6 ( 5 -year ocean age). Four percent of the juveniles detected at Bonneville returned as jacks (age 2, 1-ocean; Table 11).

Table 11. Total number of PIT-tagged fish detected at return to Bonneville Dam by ocean age (years). Values shaded yellow are subject to change based on 4-ocean returns.

| MigrationYear | Number of returning adults |  |  |  |  |  | Percentage (\%) |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Age 1 | Age 2 | Age 3 | Age 4 | Age 5 | Total | Age 1 | Age 2 | Age 3 | Age 4 | Age 5 |
| 2010 | 7 | 21 | 79 | 19 | 0 | 126 | 5.56 | 16.67 | 62.70 | 15.08 | 0.00 |
| 2011 | 33 | 170 | 339 | 53 | 2 | 597 | 5.53 | 28.48 | 56.78 | 8.88 | 0.34 |
| 2012 | 0 | 19 | 106 | 32 | 0 | 157 | 0.00 | 12.10 | 67.52 | 20.38 | 0.00 |
| 2013 | 1 | 49 | 40 | 8 | 0 | 98 | 1.02 | 50.00 | 40.82 | 8.16 | 0.00 |
| 2014 | 1 | 2 | 14 | 1 | 0 | 18 | 5.56 | 11.11 | 77.78 | 5.56 | 0.00 |
| 2016 | 4 | 26 | 47 | 2 | 0 | 79 | 5.06 | 32.91 | 59.49 | 2.53 | 0.00 |

## 4. Acknowledgment

We thank all of the crews whose collective fish-tagging efforts over the years made this study possible. We are also grateful to David Lind who reviewed, edited and provided valuable comments in the draft report. We would also like to thank Daylen Isaac who provided the hydrological data.
