# YAKIMA/KLICKITAT FISHERIES PROJECT MONITORING AND EVALUATION Yakima Subbasin 

PROJECT NUMBER 1995-063-25
Report covers work performed under BPA contract \#00056662 REL 135
Report was completed under BPA contract \#00056662 REL 140

FINAL REPORT<br>For the Performance Period<br>May 1, 2017 through April 30, 2018<br>July 31, 2018<br>Melvin R. Sampson, Policy Advisor/Project Coordinator<br>David E. Fast, Research Manager<br>William J. Bosch, Editor<br>Yakima/Klickitat Fisheries Project<br>THE CONFEDERATED TRIBES AND BANDS OF<br>THE YAKAMA NATION<br>Toppenish, WA 98948

Submitted: August 14, 2018

This report was funded by the Bonneville Power Administration (BPA), U.S. Department of Energy, as part of BPA's program to protect, mitigate, and enhance fish and wildlife affected by the development and operation of hydroelectric facilities on the Columbia River and its tributaries. The views in this report are the authors' and do not necessarily represent the views of BPA.

This report should be cited as follows:

## Acknowledgements

Monitoring and evaluation efforts in the Yakima River Basin are the result of a cooperative effort by many individuals from a variety of agencies including the Yakama Nation Fisheries Program, the Washington Department of Fish and Wildlife, the United States Fish and Wildlife Service, the Columbia River Inter-Tribal Fish Commission, the National Oceanic and Atmospheric Administration Fisheries department as well as some consultants and contractors. We also wish to acknowledge and thank the Yakama Nation Tribal Council, U.S. Bureau of Reclamation, Yakima Subbasin Fish and Wildlife Recovery Board, Pacific States Marine Fisheries Commission, U.S. Forest Service Naches Ranger District, University of Idaho, Lars Mobrand and associates, University of Washington, and Central Washington University for their many contributions to this project including both recommendations and data services.

The core project team includes the following individuals: Mel Sampson, Dave Fast, Mark Johnston, Bill Bosch, David Lind, Paul Huffman, Joe Hoptowit, Bill Fiander, Todd Newsome, Melinda Davis, Michael Porter, Sara Sohappy, Chris Frederiksen, Jim Matthews, and a number of technicians from the YN; Charles Strom and a number of assistants from the Cle Elum Supplementation and Research Facility; Joe Blodgett and the crew at the Prosser Hatchery; John Easterbrooks (retired), Anthony Fritts, Gabe Temple, Christopher Johnson, and a number of assistants from the WDFW; Curt Knudsen from Oncorh Consulting and Doug Neeley from IntSTATS Consulting. We also receive considerable support from: Sharon Lutz, Susan Gutenberger and assistants from the USFWS; Don Larsen, Andy Dittman, and assistants from NOAA Fisheries; Zach Penney, Doug Hatch, Peter Galbreath and many others at the Columbia River Inter-Tribal Fish Commission; and Charlie Waters, Kerry Naish, and others at the University of Washington.

Special acknowledgement and recognition is owed to all of the dedicated Yakama Nation and YKFP personnel working on various tasks including Ray Decoteau, Joe Yallup, Leroy Senator, Sy Billy, Wayne Smartlowit, Morales Ganuelas, Pharamond Johnson, Steve Salinas, Shiela Decoteau, Jimmy Joe Olney, Conan Northwind, Quincy Wallahee, Andrew Lewis, Nate Pinkham, Gene Sutterlick Germaine Hart, Jamie Bill, Nate Pinkham, William Manuel, Terrance Compo, Levi Piel, Winna Switzler, Florence Wallahee, Ted Martin and Arnold Barney. The accomplishments and achievements documented here are a direct result of their dedication and desire to seek positive results for the betterment of the resource. Also, these achievements are attainable because of the efficient and essential administrative support received from all of the office and administrative support personnel for the YKFP including: Ida Ike, Joanne Fernandez, Shirley Alvarado, and Adrienne Wilson.

We would especially like to thank former contributors to the Yakima/Klickitat Fisheries Project including Bruce Watson, Joel Hubble, Steve Schroder, Todd Pearsons, Craig Busack, Ray Brunson, Joy Evered, Joe Jay Pinkham III, and Bill Hopley. These individuals put in countless hours of hard work during the planning, design, and implementation of this project. Their contributions helped to lay a solid foundation for this project and our monitoring and evaluation efforts. Dan Barrett (retired) served as the manager of the CESRF from 1997-2002. He helped to lay a solid foundation for the critical work done day in and day out at the Cle Elum facility.

This work is funded by the Bonneville Power Administration (BPA) through the Northwest Power and Conservation Council's (NPCC) Fish and Wildlife Program. Michelle O'Malley is BPA's contracting officer and technical representative (COTR) for this project. David Byrnes and Patricia Smith served as COTRs in the past and contributed substantially to the project over the years.

## Executive Summary

The Yakima-Klickitat Fisheries Project (YKFP) is a joint project of the Yakama Nation (lead entity) and the Washington State Department of Fish and Wildlife (WDFW) and is sponsored in large part by the Bonneville Power Administration (BPA) with oversight and guidance from the Northwest Power and Conservation Council (NPCC). It is among the largest and most complex fisheries management projects in the Columbia Basin in terms of data collection and management, physical facilities, habitat enhancement and management, and experimental design and research on fisheries resources. The YKFP is attempting to evaluate all stocks historically present in the Yakima Subbasin and apply a combination of habitat restoration and hatchery supplementation or reintroduction, to restore the Yakima Subbasin ecosystem with sustainable and harvestable populations of salmon, steelhead and other at-risk species. This project and report address regional monitoring and evaluation strategies and sub-strategies as they apply to spring Chinook, summer/fall Chinook, and coho work in the Yakima Subbasin. This project (199506325) is related to numerous other projects in the Yakima Subbasin; additional information is available in the annual reports of these related projects.

The YKFP began a spring Chinook salmon hatchery program at the Cle Elum Supplementation and Research Facility (CESRF) near Cle Elum on the upper Yakima River in 1997. This program is a supplementation effort targeting the upper Yakima River population and is designed to test whether artificial propagation can be used to increase natural production and harvest opportunities while limiting ecological and genetic impacts. It is an integrated hatchery program because only natural-origin brood-stock is used and returning hatchery-origin adults are allowed to spawn in the wild. The program employs "best practice" hatchery management principles including reduced pond densities, strict disease management protocols, random brood-stock selection, and factorial mating to maximize effective population size. Fish are reared at the central facility, but released from three acclimation sites located near the central facility at: Easton approximately 25 km upstream of the central facility, Clark Flat about 25 km downstream of the central facility, and Jack Creek about 12 km upstream from the Teanaway River's confluence with the Yakima River. The CESRF collected its first spring Chinook brood-stock in 1997, released its first fish in 1999, and age-4 adults have been returning since 2001. The first generation of offspring of CESRF and wild fish spawning in the wild returned as adults in 2005. The program uses the adjacent, un-supplemented Naches River population as an environmental and wild control or reference system.

Adult returns of fall Chinook to the Yakima River Basin consist mostly of hatcheryorigin fish returning from releases averaging 1.6 million Upriver Brights annually from
the Prosser Hatchery which have occurred since 1983. Summer-run Chinook were extirpated from the Yakima Basin by 1970. To increase the temporal and spatial distribution of summer/fall run Chinook in the Yakima River Subbasin, the program began releases of Wells Hatchery summer-run Chinook in the Yakima River Basin in 2009. Coho were extirpated from the Yakima Subbasin by the early 1980s. Pursuant to U.S. v. Oregon court-mandated agreements, substantial numbers (annual average $>$ 700,000 ) of hatchery-reared coho salmon were released into the Yakima River since the mid-1980s. Prior to 1996 the primary purpose of releases was harvest augmentation and fish were released in sub-optimal spawning and rearing areas below Wapato Dam. With the inception of the YKFP in 1996, the objective of the coho program became "to determine the feasibility of reestablishing a naturally spawning coho population" and releases were moved upriver to more suitable habitats for natural coho.

Annual abundance of spring Chinook at Prosser Dam has increased from a 1982-2000 average of about 4,000 fish to a 2001-2017 average of over 11,000 fish. These increases can be attributed to returns from the Cle Elum supplementation program beginning in 2001, improved freshwater passage conditions, improved marine survival, and habitat restoration and enhancement work. Annual abundance of summer/fall Chinook at Prosser Dam has increased from a 1983-1999 average of just over 1,000 fish to a 2000-2017 average of over 4,500 fish. While this increase coincides with improved ocean conditions, some of the increase may also be due to improved passage in the mainstem Columbia River, changes in the lower Yakima River that are making fish seek more amenable spawning areas further upriver, and improvements in spawning and rearing protocols. Approximately 600 summer-run Chinook were estimated to pass above Prosser Dam in 2017. In 2017, over 3,000 coho returned above Prosser Dam. Coho returns to Prosser Dam averaged over 6,000 fish from 1997-2017 (an order of magnitude improvement from the average for years prior to the project) including estimated returns of wild/natural coho averaging over 900 fish annually since 2001.

Trends in adult productivity indices for Yakima Basin natural-origin spring Chinook appear to be very similar for both Upper Yakima and Naches populations. Trends in adult productivity indices for natural-origin coho are not as clear. Under present conditions, productivity for spring Chinook appears to peak at about 1,000 to 1,500 spawners and decline as spawner abundance approaches 2,000 fish or greater. These data indicate that density-dependent limiting factors depress natural productivity at fairly low population abundance in the Yakima River Basin. Until these factors are fully addressed, supplementation yields higher overall productivity rates and can be used to return adults to fisheries and to augment natural spawning populations.

For juvenile migration years 2000-present, annual abundance estimates of juvenile smolts migrating downstream at Prosser Dam averaged 248,200 wild/natural spring Chinook, 375,500 CESRF-origin spring Chinook, 44,400 wild/natural-origin coho, and 258,700 hatchery-origin coho. Preliminary smolt-to-adult survival indices averaged approximately $2.5 \%$ and $3.1 \%$ for natural-origin spring Chinook and coho, respectively. Because of many complexities associated with the production of smolt indices, these data are useful for analysis of trends but should not be used as direct citations of, or for comparisons of marked and unmarked, smolt-to-adult survival rates. Substantial juvenile mortality occurs as smolts migrate through the Yakima River system. Strategies have been proposed to address limiting factors and improve survival of emigrating Yakima Basin juveniles. As these strategies are implemented, we expect smolt and smolt-to-adult survival to improve.

Spatial distribution of spring Chinook spawners has increased as a result of acclimation site location, salmon homing fidelity and more fully seeding preferred spawning habitats. Spring Chinook redd counts in the Teanaway River increased from a pre-supplementation average of 3 redds per year to a post-supplementation average of 63 redds per year. Fall Chinook redd distribution in the Yakima River Basin appears to be experiencing a transition with an increasing proportion of redds observed above Prosser Dam in the most recent decade. This change is primarily attributed to substantial changes in lower Yakima River habitats in recent years. Redd counts and spatial distribution of coho have increased substantially in recent years, with about 225 redds enumerated annually on average in tributaries in the upper watersheds since 2004. In 2017, 177 coho redds were observed in tributaries in the Naches and Upper Yakima Subbasins.

Monitoring and evaluation of diversity metrics is presently focused on the CESRF spring Chinook program in the Upper Yakima River. Generally, we have detected small, but significant differences between hatchery- and natural-origin fish in some juvenile and adult traits with many results already published in the peer-reviewed literature.

In spite of slight increases observed in 2016 samples in both drainages and again in 2017 in the Naches drainage, overall average fine sediment levels in the Naches and Upper Yakima River subbasins over many years of sampling continue to trend downward.

We believe Yakima Basin spring Chinook contribute minimally to marine fisheries as their spatial and temporal ocean migration patterns do not appear to intersect with marine fisheries. However, Yakima Basin fall- and summer-run Chinook and coho do contribute substantially to marine fisheries and to mainstem Columbia River fisheries
from the mouth to the Hanford Reach area. Recreational spring Chinook fisheries have returned to the Yakima River Basin after a 40 -year absence. This has contributed to improved relationships between all the Basin's stakeholders and increased opportunities for collaboration.

Supplementation has increased spring Chinook redd abundance in the Upper Yakima relative to the Naches control system. We observed an average increase in redd counts in the upper Yakima about $62 \%$ greater than that in the Naches system from the pre- to post-supplementation periods. Natural-origin returns of adult spring Chinook in the post-supplementation period (2005-2017) were maintained or increased in the supplemented Upper Yakima River and appear to be declining in the Naches control system relative to the pre-supplementation period (1982-2004). After three generations of study, the results (many of which are published in the peerreviewed literature) from the spring chinook supplementation program in the Upper Yakima River demonstrate that a well-designed and carefully managed integrated hatchery program using $100 \%$ natural-origin broodstock can produce fish for harvest and return fish to the natural spawning grounds with minimal negative impacts to the target ecosystem. Coho re-introduction research in the published literature suggests that hatchery-origin coho, with a legacy of as many as 10 to 30 generations of hatchery-influence, can reestablish a naturalized population after as few as 3 to 5 generations of outplanting in the wild.

YKFP efforts to monitor and evaluate hatchery reform focus on the CESRF spring Chinook program which was designed explicitly for this purpose from its inception. By designing the program to use only natural-origin fish for brood-stock, the program has demonstrated reduced genetic divergence for the integrated program compared to a traditional segregated hatchery program. The CESRF is also meeting or exceeding scientific recommendations for proportionate natural influence (PNI) on an annual basis with a 17 -year mean annual PNI of $66 \%$. The project is thus far meeting or exceeding most other established objectives related to hatchery reform.

Major piscivorous predators in the Yakima River Basin include: common mergansers, American white pelicans, double-crested cormorants, gulls, great blue herons, northern pike minnows, and smallmouth bass. The project has initiated efforts to control the pike minnow and smallmouth bass populations.

Project results are communicated broadly through the annual science and management conference, technical reports and peer-reviewed journal publications (see references and project-related publications), and via several related web sites described in Appendix A.

## Introduction

The Yakima-Klickitat Fisheries Project (YKFP) is a joint project of the Yakama Nation (lead entity) and the Washington State Department of Fish and Wildlife (WDFW) and is sponsored in large part by the Bonneville Power Administration (BPA) with oversight and guidance from the Northwest Power and Conservation Council (NPCC). It is among the largest and most complex fisheries management projects in the Columbia Basin in terms of data collection and management, physical facilities, habitat enhancement and management, and experimental design and research on fisheries resources. Consistent with Wy-Kan-Ush-Mi Wah-Kish-Wit (CRITFC 1995) and using principles of adaptive management (Salafsky et al. 2001), the YKFP is attempting to evaluate all stocks historically present in the Yakima Subbasin and apply a combination of habitat restoration and hatchery supplementation or reintroduction, to restore the Yakima Subbasin ecosystem with sustainable and harvestable populations of salmon, steelhead and other at-risk species.

The original impetus for the YKFP resulted from the landmark fishing disputes of the 1970s, the ensuing legal decisions in United States versus Washington and United States versus Oregon, and the region's realization that lost natural production needed to be mitigated in upriver areas where these losses primarily occurred. The YKFP was first identified in the NPCC's 1982 Fish and Wildlife Program (FWP) and supported in the U.S. v Oregon 1988 Columbia River Fish Management Plan (CRFMP). A draft Master Plan was presented to the NPCC in 1987 and the Preliminary Design Report was presented in 1990. In both circumstances, the NPCC instructed the Yakama Nation, WDFW and BPA to carry out planning functions that addressed uncertainties in regard to the adequacy of hatchery supplementation for meeting production objectives and limiting adverse ecological and genetic impacts. At the same time, the NPCC underscored the importance of using adaptive management principles to manage the direction of the Project. The 1994 FWP reiterated the importance of proceeding with the YKFP because of the added production and learning potential the project would provide. The YKFP is unique in having been designed to rigorously test the efficacy of hatchery supplementation. Given the current depressed status of many salmon and steelhead stocks, and the heavy reliance on artificial propagation as a recovery tool, YKFP monitoring results have great region-wide significance.

Supplementation is envisioned as a means to enhance and sustain the abundance of wild and naturally-spawning populations at levels exceeding the cumulative mortality burden imposed on those populations by habitat degradation and by natural cycles in environmental conditions. A supplementation hatchery is properly operated as an adjunct to the natural production system in a watershed. By fully integrating the
hatchery with a naturally-producing population, high survival rates for the component of the population in the hatchery can raise the average abundance of the total population (hatchery component plus naturally-producing component) to a level that compensates for the high mortalities imposed by human development activities and fully seeds the natural environment. However, it is important to recognize that "rebuilding natural populations will ultimately depend on improving habitat quality and quantity" (ISRP 2011, Venditti et al. 2017) of which habitat connectivity is an essential component (CRITFC 1995, Milbrink et al. 2011). Hatchery programs, even "state of the art" integrated supplementation programs designed to follow all of the best management practice recommendations (Cuenco et al. 1993, Mobrand et al. 2005), do not directly affect any of these habitat parameters which are vital to improving natural productivity. Therefore, the YKFP is working with partners in multiple forums to implement habitat restoration and water resource management projects designed to address factors limiting productivity (see Yakima Subbasin, Recovery, and Integrated plans).

The objectives of the YKFP are to: enhance existing stocks; re-introduce extirpated stocks; protect and restore habitat in the Yakima Subbasin; operate using a scientifically rigorous process that will foster application of the knowledge gained about hatchery supplementation and habitat restoration throughout the Columbia River Basin; and use Ecosystem Diagnosis and Treatment (EDT) and other modeling tools to facilitate planning for project activities. In strictly scientific terms the stated purpose of the project is, "to test the assumption that new artificial production can be used to increase harvest and natural production while maintaining the long-term genetic fitness of the fish population being supplemented and keeping adverse genetic and ecological interactions with non-target species or stocks within acceptable limits" (RASP 1992, BPA 1996). WDFW is addressing some critical uncertainties (see Columbia River Basin Research Plan and Critical Uncertainties for the Columbia River Basin Fish and Wildlife Program) related to genetic and ecological interactions under project 1995-064-25. We are working jointly with WDFW and CRITFC (2009-009-00) to address fish propagation, predation, harvest, and monitoring and evaluation methodology uncertainties including:

Fish Propagation Question 1. Are current propagation efforts successfully meeting harvest and conservation objectives while managing risks to natural populations?
1.2. Can hatchery production programs meet adult production and harvest goals (integrated and segregated) while protecting naturally spawning populations?
1.4. What is the magnitude of any demographic benefit or detriment to the production of natural-origin juveniles and adults from natural spawning of hatchery-origin supplementation adults?
1.5. What are the range, magnitude and rates of change of natural spawning fitness of integrated (supplemented) populations, and how are these related to management rules including the proportion of hatchery fish permitted on the spawning grounds, and the proportion of natural origin adults in the hatchery broodstock?

Predation Question 1. Are the current efforts to address predation and reduce numbers of predators effective?

Predation Question 2. Are there actions other than removing predators that could reduce predation on listed species?

Harvest Question 1. Do current harvest and escapement strategies provide the expected results in supporting recovery efforts and providing harvest opportunities?

Monitoring and evaluation methods Question 1. Are current methods to ... count fish and to measure productivity adequate to cost effectively inform decisions?

Monitoring and evaluation methods Question 2. Are there innovative methods for counting fish and measuring their productivity that would better inform decisions?

YKFP-related project research in the Yakima River Basin has resulted in the publication of over 50 manuscripts in the peer-reviewed literature (see References and Project-Related Publications). The status of ongoing research relative to the above uncertainties is presented as part of this report.

This report includes sections on the following regional research, monitoring, and evaluation (RME) strategies: fish population status, harvest, hatchery, and predation. Each section addresses all relevant sub-strategies that apply to this project. The report addresses these strategies and sub-strategies as they apply to spring Chinook (Oncorhynchus tshawytscha), summer/fall Chinook (O. tshawytscha), and coho (O. kisutch) RM\&E work in the Yakima subbasin. Steelhead (O. mykiss) RME work is addressed in related VSP (2010-030-00), on-reservation watersheds (1996-035-01), and Kelt Reconditioning (CRITFC 2008-458-00 and 2007-401-00) projects. WDFW is addressing hatchery uncertainties related to genetic and ecological interactions under project 1995-064-25. YKFP-related habitat activities for the Yakima Subbasin are addressed under projects 1997-051-00 and 1996-035-01 (except for sediment sampling
which is addressed here). Hatchery Production Implementation ( $O \& M$ ) is addressed under project 1997-013-25. Data and findings presented in this report should be considered preliminary until results are published in the peer-reviewed literature.

Study Area
The project study area is the Yakima River Basin WRIA 37/38/39 (Figure 1).

Figure 1. Yakima River Basin and Yakama Nation/YKFP-related artificial production and monitoring facilities (map provided by Paul Huffman).

## Fish Population Status Monitoring

## Status and Trend of Adult Fish Populations (Abundance)

Methods: Adult salmon populations in the Yakima River Basin are enumerated at Prosser Dam using video equipment installed in all three adult fish ladders (monitoringresources.org methods 143, 144, 307, 418, 515). At both Prosser and Roza Dams, adult fish traps are also used on a seasonal basis for biological sampling and enumeration (monitoringresources.org methods 135). When the Roza adult trap is not in operation, video equipment is also employed at the adult fish ladders there. However, camera placement and actual viewing area are limited; these combined with water clarity issues during certain river conditions all affect video enumeration at Roza Dam. Automatic Passive Integrated Transponder (PIT) tag detectors are also employed at all fish ladders at both dams (see sites RZF and PRO in ptagis.org). For the safety and protection of personnel and equipment, video and PIT-detection equipment are removed during periods of high river flow. In these instances, biologists attempt to extrapolate fish counts using data from before and after the high flow event. Although adult passage over spillways is believed to occur when flows are favorable, Prosser Dam counts are generally considered by Yakama Nation biologists to be within $+/-5 \%$ of actual fish passage. Roza Dam counts during trap operation (generally the entire spring Chinook counting period, March-September) are considered virtually $100 \%$ accurate; however during the late fall and winter counting period when video equipment is used at least part of the time, accuracy may fall to only $50-75 \%$ of actual fish passage based on preliminary evaluation of PIT tag detection data. Fish are denoted as hatchery- or natural-origin based on presence or absence respectively, of observed external or internal marks or tags (monitoringresources.org method 342). Chinook are denoted as spring-, summer-, or fall-run based on review of PIT-detection data and visual observations of coloration and body morphometry.

At Prosser Dam, time-lapse video recorders (VHS) and a video camera were used at viewing windows at each of the three fishways. Digital video recorders (DVR) and progressive scan cameras (to replace the VHS systems) were tested at each of the three Prosser fishways in 2007 and became fully operational in February of 2008. The new system functions very similarly to the VHS system but provides digital video data readily downloadable to the viewing stations in Toppenish. This new system also allows technicians in Toppenish to scan rapidly to images of fish giving a more timely and accurate fish count. The technicians review the images and record various types of data for each fish that migrates upstream via the ladders. The data are entered into
a Microsoft Access database, and daily dam count reports are regularly posted to the ykfp.org and Data Access in Real-Time (DART) web sites. Similarly at Roza Dam, adult trap data are entered into a Microsoft Access database, and daily dam count reports (with video counts integrated) are regularly posted to the ykfp.org and DART web sites. Post-season, counts are reviewed and adjusted for data gaps and knowledge about adult and jack lengths from sampling activities. Historical final counts are posted to the ykfp.org and DART web sites. A system has been developed that serves Yakima Basin adult abundance and trap sampling data for the Prosser and Roza data sets. This system can be accessed at: http://dashboard.yakamafishstar.net/FishData.

Spring Chinook began returning from the Cle Elum Supplementation and Research Facility (CESRF) in 2000 (jacks) and 2001 (adults). All CESRF-origin spring Chinook are marked. Due to physical and logistical constraints at the Prosser Hatchery it is not possible to mark all hatchery releases of summer/fall run Chinook without jeopardizing fish health and survival but these issues are being addressed through the Master Planning process (Yakama Nation 2012). Thus, enumeration of hatchery- and natural-origin summer/fall run Chinook adult returns is not presently available but will be available in the future. New marking protocols made it possible to distinguish hatchery- and natural-origin coho beginning with return year 2001.

## Results:

Figure 2. Estimated counts of natural- and Cle Elum Supplementation and Research Facility (CESRF-) origin spring Chinook (adults and jacks) at Prosser Dam, 1982-present.

Figure 3. Estimated counts of adult and jack summer/fall run Chinook at Prosser Dam, 1983-present.

Figure 4. Estimated counts of marked (presumed hatchery-origin) and unmarked (presumed natural-origin) Coho (adults and jacks) at Prosser Dam 1986-present.

Figure 5. Estimated counts of natural- and Cle Elum Supplementation and Research Facility (CESRF-) origin spring Chinook (adults and jacks) at Roza Dam, 1982-present.

Figure 6. Average daily passage of Chinook and Coho (adults and jacks) at Prosser Dam, 2008-2017.

Figure 7. Passage timing of adult and jack Chinook at Prosser Dam in 2017 by run (see Methods).

## Discussion:

Annual abundance of spring Chinook at Prosser Dam has increased from a 1982-2000 average of about 4,000 fish to a 2001-2017 average of over 11,000 fish (Figure 2). Annual abundance of spring Chinook at Roza Dam has increased from a 1982-2000 average of about 2,300 fish to a 2001-2017 average of approximately 7,100 fish (Figure 5). These increases can be attributed to returns from the Cle Elum supplementation program beginning in 2001, improved freshwater passage conditions, improved marine survival, and habitat restoration and enhancement work. The lowest adult returns since 2000 followed two years after the notable droughts which occurred during smolt outmigration years 2001 and 2005. Discussion of uncertainties relating to the Cle Elum spring Chinook supplementation program is included under Hatchery Monitoring later in this report. Additional data and detail on the Cle Elum spring Chinook supplementation program and the status of natural- and CESRForigin spring Chinook in the Yakima River Basin are provided in Appendix B.

Although some natural production is occurring, adult returns of fall Chinook to the Yakima River Basin consist mostly of hatchery-origin fish returning from annual releases of Upriver Brights from the Prosser Hatchery which have occurred since 1983 and averaged about 1.9 million since 1999 (Yakama Nation 2012). In addition, the Yakama Nation has a goal of re-establishing Summer-run Chinook which were extirpated from the Yakima Basin by 1970. Pursuant to this goal we began releases of Wells Hatchery summer-run Chinook in the Yakima River Basin in 2009. Annual abundance of summer/fall Chinook at Prosser Dam has increased from a 1983-1999
average of just over 1,000 fish to a 2000-2017 average of over 4,500 fish (Figure 3). While this increase coincides with improved ocean conditions, some of the increase may also be due to improved passage in the mainstem Columbia River, changes (e.g., increased aquatic vegetation like stargrass Heterantera dubia, Wise et al. 2009) in the lower Yakima River that are making fish seek more amenable spawning areas further upriver, and improvements in spawning and rearing protocols. By re-establishing the summer-run component we seek to increase the temporal (Figures 6 and 7) and spatial distribution of summer/fall run Chinook in the Yakima River Subbasin (Yakama Nation 2012). Approximately 600 summer-run Chinook were estimated to pass above Prosser Dam in 2017 (Figure 7).

Coho were extirpated from the Yakima Subbasin by the early 1980s. Pursuant to U.S. v. Oregon court-mandated agreements, substantial numbers (annual average $>700,000$ ) of hatchery-reared coho salmon were released into the Yakima River since the mid1980s. Prior to 1996 the primary purpose of releases was harvest augmentation and fish were released in sub-optimal spawning and rearing areas below Wapato Dam. With the inception of the YKFP in 1996, the objective of the coho program became "to determine the feasibility of reestablishing a naturally spawning coho population" and releases were moved upriver to more suitable habitats for natural coho. Monitoring of these efforts to re-introduce a sustainable, naturally spawning coho population in the Yakima Basin have indicated that coho returns averaged over 6,000 fish from 1997-2017 (an order of magnitude improvement from the average for years prior to the project) including estimated returns of wild/natural coho averaging over 900 fish annually since 2001 (Figure 4).

## Status and Trend of Adult Productivity

## Methods:

We used recruit-per-spawner relationships (Ricker 1975) to describe adult-to-adult productivity indices. Species-specific methods were as follows.

## Spring Cbinook.

Estimated natural-origin spawners for the Upper Yakima River were calculated as the estimated escapement above Roza Dam plus the estimated number of spawners between the confluence with the Naches River and Roza Dam. Total natural-origin returns to the Upper Yakima River were developed using run reconstruction techniques (Appendix B). Age composition for Upper Yakima returns was estimated from spawning ground carcass scale samples (monitoring resources.org method 112) for the years 1982-1996 and from Roza Dam brood-stock collection samples (Knudsen et al. 2006; Appendix B) for the years 1997 to present. Since age-3 fish
(jacks) are not collected for brood-stock in proportion to the jack run size, the proportion of age-3 fish in the upper Yakima for 1997 to present was estimated using the proportion of jacks (based on visual observation) counted at Roza Dam relative to the total run size.

Estimated spawners and total returns for Naches River Subbasin natural-origin spring Chinook were calculated using run reconstruction techniques (Appendix B). Age composition for Naches Basin age-4 and age-5 returns were estimated from spawning ground carcass scale samples (monitoring resources.org method 112). The proportion of age-3 fish was estimated after reviewing jack count (based on visual observations) data at Prosser and Roza dams.

Estimated spawners at the CESRF were the total number of wild/natural fish collected at Roza Dam and taken to the CESRF for production brood-stock (Knudsen et al. 2006; Appendix B). Total returns of CESRF-origin fish were based on run reconstruction and Roza dam sampling operations. Age composition for CESRF fish was estimated using scales and PIT tag detections from CESRF fish sampled passing upstream through the Roza Dam adult monitoring facility (Knudsen et al. 2006; Appendix B).

## Coho

From central British Columbia south, the vast majority of coho salmon adults are 3-year-olds, having spent approximately 18 months in fresh water and 18 months in salt water (Loeffel and Wendler 1968, Wright 1970). Therefore we estimated a naturalorigin productivity (recruits per spawner) index by dividing natural-origin returns to Prosser Dam by the estimated returns to Prosser Dam three years prior. We computed this index for both adult and combined adult and jack returns per adult and combined adult and jack spawner. Note that this method will bias productivity estimates high, as it assumes no natural production from hatchery-origin spawners.

## Summer/Fall Run Cbinook.

Adult fall Chinook returning to the Yakima Basin consist of hatchery-origin returns from releases at and above Prosser Dam and natural-origin returns from fish spawning naturally in the Yakima River. Due to fiscal, physical, logistical, and policy considerations, only a small proportion of hatchery-origin releases have been externally marked. Therefore it is impossible at present to know the origin of unmarked adult fall Chinook counted at Prosser. Additional marking is proposed for hatchery-origin releases as part of the Master Plan (Yakama Nation 2012), which will allow development of a comprehensive brood/cohort age at return table for naturaland hatchery-origin returns. Methods and results for evaluating adult productivity of
summer/fall run Chinook will be included in future reports and publications as the data become available.

## Results:

Table 1. Adult-to-adult productivity indices for upper Yakima wild/natural spring Chinook.

| Brood <br> Year | Estimated Spawners | Estimated Yakima R. Mouth Returns |  |  |  | Returns/ Spawner |

Figure 10. Productivity indices for age-3 natural-origin coho, brood years 2001-2014.

## Discussion:

Trends in adult productivity indices for Yakima Basin natural-origin spring Chinook appear to be very similar for both Upper Yakima (Figure 8) and Naches (Figure 9) populations. The trend in adult productivity indices for natural-origin coho (Figure
10) is not as obvious, and 2014 marked the first year that we observed high coho spawner escapements (when hatchery-origin spawning escapement is included) similar to those we have observed with spring Chinook in some recent years. Under present conditions, productivity for spring Chinook appears to peak at about 1,000 to 1,500 spawners and declines as spawner abundance approaches 2,000 fish or greater (Figures 8-9). These data indicate that density-dependent limiting factors (see YSFWPB 2004) depress natural productivity at fairly low population abundance in the Yakima River Basin, as is the case for most salmon populations throughout the Columbia River Basin (ISAB 2015). Until these factors are fully addressed, supplementation yields higher overall productivity rates and can be used to return adults to fisheries and to augment natural spawning populations (Table 3). While higher spawner abundances under present conditions do not yield increased adult production, these fish still contribute to more fully seeding available habitats, increased spatial and temporal diversity, and nutrient enhancement that should eventually lead to increased natural food supply and higher productivity in the future (NRC 1996, see especially pp. 368-369; Kiffney et al. 2014).

## Status and Trend of Juvenile Abundance

Methods: The Yakama Nation releases a number of hatchery-origin smolts annually pursuant to U.S. v Oregon Management Agreements. Adult returns from these releases serve to mitigate for lost harvest opportunity (due to alteration of the Columbia River ecosystem and associated losses in natural production and productivity), to augment the number of fish spawning naturally (supplementation), or a combination of the two. Juveniles are released from many locations as yearlings or subyearlings depending on the goals of the specific programs. As these juveniles migrate downstream, they are mixed with naturally produced juveniles.

Above Prosser Dam, a portion of the river flow is diverted into the Chandler canal to generate electrical power and serve irrigation districts downstream. Juvenile fish are diverted into the Canal (and subsequently the Chandler juvenile monitoring facilityCJMF, Figure 1) at different rates depending on river and canal flow. Smolt sampling efforts at the CJMF near Prosser Dam were conducted annually from early winter through early summer corresponding with salmon smolt out-migrations. A portion of entrained salmon outmigrants (regulated by a timed gate) was manually counted and sampled for biological data on a daily basis and all PIT tagged fish were interrogated. Sampling methods were described in Busack et al. (1997) and were consistent with monitoringresources.org methods 1562, 1563, 1595, and 1614.

Paired releases of PIT-tagged smolts were made in order to estimate the fish entrainment and canal survival rates in relation to river conditions and canal operations. For outmigration years 1999 through 2014, these data were used to generate a multi-variate river flow/canal entrainment relationship (D. Neeley 2010 and 2012a). Over a range of flow diversion rates, juvenile fish entrainment rates generally fit a logistic curve: at low diversion rates, the entrainment rate is lower than the diversion rate, and at high diversion rates the entrainment rate is higher than the diversion rate. In recent years it became difficult to adapt the model to higher winter and spring flows and to river channel changes, partly because at low diversion rates it was difficult to capture enough fish to get many point estimates of entrainment rate. The releases that were made, however, still tended to support a low entrainment rate relative to diversion rate at high river flows. For some years, Prosser smolt passage estimates produced by this model were outside of what were considered reasonable bounds (e.g., entrainment-based Prosser passage estimates approached or even exceeded known releases for hatchery-origin spring Chinook far upstream). This required us to reevaluate and change our methodology. The proportions of all PITtagged smolts released above Prosser and detected at mid-Columbia dams that were previously detected in the Chandler Canal bypass now serve as estimates of bypassdetection efficiency. Expanded Prosser passage estimates were then derived using the juvenile sample counts and these detection efficiencies as described in Appendix C. These methods were generally consistent with monitoringresources.org methods 435, 623 and 1743.

## Results and Discussion:

At the CESRF, the number of release groups and total number of spring Chinook released diverged from the facility goal of 810,000 smolts in some years. In brood year 1997, the Jack Creek acclimation facility was not yet complete and project policy and technical teams purposely decided to under-collect brood stock to allow a methodical testing of the new facility's operations with less risk to live fish, which resulted in the stocking of only 10 of the 18 raceways. In brood year 1998, the project did not meet facility release goals due to a biological specification that no more than $50 \%$ of returning wild fish be taken for brood stock. As a result only 16 raceways were stocked with progeny of the 1998 brood. In the same year, raceway 4 at the Jack Creek acclimation site suffered mechanical failures causing loss of flow and reduced oxygen levels and resulted in the loss of approximately one-half the fish in this raceway prior to release. In the drought year of 2001, a large number of returning adults presented with high enzyme-linked immunosorbent assay (ELISA) levels of Renibacterium salmoninarum, the causative agent of bacterial kidney disease (BKD). The progeny of these females were purposely destroyed. As a result, only nine raceways were stocked with fish. The project decided to use the fish from an odd raceway for a
predator avoidance training sub-experiment (these fish were subsequently acclimated and released from the Easton acclimation site).

1. Brood years 1997-2001: Optimum Conventional Treatment (OCT). Brood Years 2002-2004: Normal (High) growth. Brood Years 2005-2012: Normal feed at Cle Elum or accl. sites.
2. Brood years 1997-2001: Semi-natural Treatment (SNT). Brood Years 2002-2004: Slowed (Low) growth. Brood Year 2005, 2007-2012: saltwater transition feed at accl. Sites; 2014: BioPro vs BioVIT. Brood Year 2006: EWS diet at CESRF through May 3, 2007.
3. CFJ=Clark Flat; ESJ=Easton; JCJ=Jack Creek.
4. At the Jack Creek acclimation site only 4 of 6 raceways were stocked, and raceway 4 suffered mechanical failures resulting in the loss of about 20,000 OCT (control) fish.
5. High BKD incidence in adult broodstock reduced production to just 9 ponds (Clark Flat 1-2, Jack Creek, and Easton). Easton ponds were used for predator avoidance trained (PAT) fish and a single Cle Elum pond was spread between 6 ponds at Easton with crowders used to simulate pond densities for fish at other acclimation sites. These releases were excluded from mean pond density calculations by treatment.
6. At the Jack Creek acclimation site raceway 3 suffered mechanical failures resulting in the loss of about 45,000 high-growth (control) fish.

| Release |

1. All fish released as subyearlings unless otherwise noted.

For smolt migration years 2000 to present, annual abundance estimates of juvenile smolts migrating downstream at Prosser Dam averaged 248,200 wild/natural spring Chinook, 375,500 CESRF-origin spring Chinook, 44,400 wild/natural-origin coho, and 258,700 hatchery-origin coho (Table 9). These are the years for which our data and methods are considered most reliable. Juvenile passage estimates for earlier years are provided below under "Status and Trend of Juvenile Productivity"; however, the reader should be aware that we have less confidence in these data because we have refined data collection protocols and passage estimation methods over time. As the majority of fall Chinook smolt migrants are unmarked hatchery-origin fish, we provide only the gross abundance indices below under "Status and Trend of Juvenile Productivity". The reader is cautioned to pay particular attention to the factors complicating estimates of juvenile abundance and productivity described under "Status and Trend of Juvenile Productivity".

## Status and Trend of Juvenile Migration Survival to McNary Dam

Methods: For all species, releases of PIT tagged smolts provided a means to estimate smolt survival to McNary Dam. PIT-tag detectors were located in or near the exit(s) from the release sites (monitoringresources.org 1558) and allowed estimation of the number of PIT-tagged fish leaving the release sites. To estimate the survival of smolts detected leaving the release sites that eventually pass McNary Dam, the proportion of PIT-tagged smolts detected leaving the release sites that were later detected at McNary Dam was divided by McNary Dam's detection efficiency. The estimated detection efficiency was the number of smolts detected passing dams downstream of McNary that were previously detected passing McNary divided by the total number of smolts passing the downstream dams, whether or not the smolts were previously detected at McNary. These methods were generally consistent with Sandford and Smith (2002) and with monitoringresources.org methods 623 and 1536 . We used weighted logistic or weighted least squares analysis of variance to analyze differences in survival metrics and indices between various release sites, years and treatments. Additional detail, results and discussion are provided in Appendices C-H.

## Results and Discussion:

For spring Chinook, we compared survivals to McNary Dam of CESRF hatchery-and natural-origin PIT-tagged smolts released into the Roza Dam bypass and migrating downstream of Roza Dam contemporaneously on or after March 16. This date was selected because CESRF fish were not allowed to begin volitional emigration from the acclimation sites until March 15. Approximately $81 \%$ of natural-origin spring Chinook smolts PIT-tagged and released at Roza since 1999 migrated downstream of Roza Dam prior to March 16 (derived using queries of PTAGIS database 7/12/2013). Natural and hatchery-origin smolts contemporaneously migrating past Roza from March 16 on are referred to as "late" migrants.

Survival to McNary Dam for late-migrating natural-origin smolts exceeded that of the hatchery-origin smolts in 15 of the 17 outmigration years (Figure 11; D. Neeley, Appendix D). The pooled survival estimate was significantly higher for the natural-
origin smolts. Survival analyses for additional spring Chinook treatments are presented in Appendices E and F of this report.

Figure 11. Upper-Yakima Spring-Chinook Roza-to-McNary Smolt Survival for late-migrating (>March 15) Natural- (solid lines and filled diamonds) and Hatchery-origin (dashed lines and clear diamonds) Smolts. No releases occurred in 2014 because of another study conducted at Roza in that year. Pooled weighted mean was estimated using yearly release number as a weighting variable of survival percentages. Source: $D$. Neeley, Appendix D.
We estimated juvenile survival to McNary Dam for summer- and fall-run Chinook. Subyearling and yearling fall Chinook were released from Prosser for migration years 2008 through 2017. Summer-run Chinook subyearlings were released from Stiles pond in outmigration-years 2009 through 2011, from Nelson Springs (Buckskin Slough) in 2011 through 2015, from Prosser and Marion Drain in 2012, and from Roza Dam in 2013-14 (for locations see Figure 1). Estimates of release-to-McNary survival for these releases are presented in Appendix G. Data for subyearling fall-run Chinook suggest that smolt survival was reduced in the most recent three years compared to 2008-2014 (Figure 12).

$\square 2008 \square 2009 \square 2010 \square 2011 \square 2012 \square 2013 \square 2014 \square 2008-2014$ Pooled* $\square 2015 \square 2016 \square 2017 \square 2015-2017$ Pooled*
Figure 12. Pooled Prosser-to-McNary Survival for Yakima Stock Subyearling Fall Chinook Releases made in 2008 through 2017.

The 2015 releases were associated with record low snow packs in the Cascade Mountains and a severe drought. For those release sites used in previous years, survival of all tagged smolt to McNary Dam (McNary) in 2015 was the lowest experienced. Because of the exceptional conditions in 2015, some fish were trucked to the mouth of the Yakima River for release. Survival for summer- and fall-run Chinook releases made from all release sites and release dates in 2015 were abysmal except for the earliest release of Fall Chinook at the mouth of the Yakima River. Survival of 2009 summer run releases was also poor due to a later release date and blockage of some irrigation diversion screen bypasses. We continued to experiment with different timing (early May through late June) and locations (Prosser Dam to the Yakima River mouth) in 2016-17 for both fall- and summer-run Chinook in an effort to determine ways to improve survival.

For coho, we estimated survival from acclimation site release to McNary Dam based on timing, location and brood source of the releases. Results are given in Appendix H.

The data indicate that there are substantial sources of juvenile mortality limiting survival of smolts migrating from release sites in the Yakima River basin. The YKFP is working with partners in multiple forums to implement habitat restoration and water resource management projects that address factors limiting survival and productivity (see Yakima Subbasin, Recovery, and Integrated plans).

## Status and Trend of Juvenile Productivity (smolt-to-adult returns)

## Methods:

Smolt abundance passage estimates at Prosser and the methods used to derive them were described above. For spring Chinook, adult return estimates to the Yakima River mouth were derived using Prosser and Roza adult abundance and harvest data (described in other sections of this report and in Appendix B) and run reconstruction techniques (Appendix B). For coho, we used Prosser adult abundance.

Adult fall Chinook returning to the Yakima Basin consist of hatchery-origin returns from releases at and above Prosser Dam and natural-origin returns from fish spawning naturally in the Yakima River. Due to fiscal, physical, logistical, and policy considerations, only a small proportion of hatchery-origin releases have been externally marked. Therefore it is impossible at present to know the origin of unmarked adult fall Chinook counted at Prosser. Additional marking is proposed for hatchery-origin releases as part of the Master Plan (Yakama Nation 2012). To derive rough smolt-to-adult return indices for fall Chinook, aggregate (marked and unmarked
combined) smolt passage estimates for the age-3, -4 , and -5 components for a given return year were averaged and the aggregate adult passage estimate for that return year was divided by this average smolt passage estimate. For example, the "Prosser Average Smolts" for adult return year 1988 is the average of marked and unmarked Prosser smolt estimates for juvenile migration years 1983-1985.

## Results:

Table 10. Estimated smolt passage at Chandler and smolt-to-adult return indices (Chandler smolt to Yakima R. mouth adult) for Yakima Basin wild/natural and CESRF-origin spring Chinook.

1. Mean flow (cfs) approaching Prosser Dam March 29-July 4 of juvenile migration year. No data available for migration year 1991. In high flow years (flows at or > 5000 cfs) operation of the Chandler smolt sampling facility may be precluded during portions of the outmigration. Data courtesy of U.S. BOR hydromet.
2. Aggregate of Upper Yakima, Naches, and American wild/natural populations.
3. Estimated smolt-to-smolt (release from upper Yakima River acclimation sites to Chandler) survival for CESRF juveniles.
4. Includes combined age-3 through age-5 returns. CESRF adult returns and smolt-to-adult survival values are understated relative to wild/natural values since these figures are not adjusted for differential harvest rates in mark selective fisheries in marine and lower Columbia River fisheries.
5. Available data were not sufficient to estimate juvenile flow-entrainment and passage of wild/natural fish.
6. Data for most recent year are preliminary; return data do not include age-5 adult fish.

Table 11. Average combined hatchery- and natural-origin smolt counts at Prosser for fish returning at age-3, -4, and -5, combined adult returns to Prosser Dam of all age classes, and estimated Prosser smolt-to-adult return indices for Yakima River fall-run Chinook for adult return years 1988-2017.

${ }^{\text {a }}$ Yakama Nation estimates of coho smolt passage at Chandler.
${ }^{\mathrm{b}}$ Yakama Nation estimates of age-2 and age-3 coho returns to Prosser Dam for this juvenile migration cohort.
${ }^{\text {c }}$ Average estimate derived from PIT-tag detections of Taneum Creek natural coho for juvenile migration years 2009-2011.
${ }^{\mathrm{d}}$ Excludes migration year 2003.

## Discussion:

Calculation of smolt-to-adult survival rate indices for Yakima Basin anadromous salmonids are complicated by the following factors:

1) Smolt accounting at Prosser is based on statistical expansion of Chandler smolt trap sampling data using available PIT-detection and flow data and estimated Chandler entrainment rates. Chandler smolt passage estimates are prepared primarily for the purpose of comparing relative marked versus unmarked passage estimates and not for making survival comparisons. While these Chandler smolt passage estimates represent the best available data, there may be a high degree of error associated with these estimates due to inherent complexities, assumptions, and uncertainties in the statistical expansion process. Therefore, these estimates are subject to revision.
2) Large numbers of Yakima Basin salmonid releases (all CESRF spring Chinook) are adipose-fin clipped and subjected to higher harvest rates than unmarked wild/natural fish in marine and Columbia River mark-selective fisheries. No
adjustments have yet been made in the above SAR estimates to account for differential harvest rates in these mark-selective fisheries.
3) Due to issues such as water diversion permitting, size required for tagging, and allowing sufficient time for acclimation, release time for many hatchery-origin juveniles (including all CESRF spring Chinook) may be delayed relative to their wild counterparts. For example, spring Chinook from the CESRF are not allowed to volitionally migrate until at least March 15 of their smolt outmigration year; however, juvenile sampling observations at Roza Dam indicate that a substantial number of wild/natural juveniles migrate downstream during the summer, fall, and winter months prior to their smolt outmigration year. Analysis of juvenile migrant PIT detections at Roza Dam (PTAGIS queries run 7/12/2013) indicated that approximately $81 \%$ of natural-origin spring Chinook migrated downstream of Roza in the fall or winter as juveniles (before CESRF fish would have the opportunity). Comparison of SAR data for non-contemporaneously migrating juveniles may be invalid.

Given these complicating factors, Tables 10-12 present available smolt-to-adult survival indices for Yakima River spring and summer/fall Chinook and coho. Because of the complexities noted above, these data are useful for analysis of trends but should not be used as direct citations of, or for comparisons of marked and unmarked, smolt-to-adult survival rates. The reader is encouraged to contact Yakama Nation technical staff to discuss these and other issues prior to any use of these data or any other estimation of Yakima Basin SARs that may be available through data obtained from public web sites such as RMPC, PTAGIS, DART, FPC or others.

Substantial juvenile mortality of subyearling releases of summer- and fall-run Chinook occurs in the Yakima River between their release sites and McNary Dam (Neeley 2012b). Strategies have been proposed to address limiting factors (YSFWPB 2004) and improve survival of these releases (Yakama Nation 2012). As these strategies are implemented, we expect SARs for summer- and fall-run Chinook to improve substantially from the estimates provided in Table 11 (Yakama Nation 2012). Additional discussion and results for Yakima Basin spring Chinook SARs are presented in Appendix B.

## Status and Trend of Spatial Distribution (Redd Counts)

Methods: Regular foot and/or boat surveys (monitoringresources.org methods 30, $131,285,1508$ ) were conducted within the established geographic range for each species (this is increasing for coho as acclimation sites are located upriver and as the run increases in size). Redds were individually marked during each survey and
carcasses were sampled to collect egg retention, scale sample, sex, and body length information and to check for possible experimental marks. River conditions vary from year to year and preclude complete accounting, especially for fall Chinook and Coho. Other agencies (WDFW, Pacific Northwest National Laboratory, and private contractors) have also conducted foot, boat, or aerial surveys for fall Chinook redds in the Yakima River Basin and we have attempted to incorporate available information from those surveys here.

## Results:

Figure 13. Redd Counts upstream of Prosser Dam in the Yakima River Basin by species, 1981-present.

Table 13. Yakima Basin spring Chinook redd counts and distribution, 1981 - present.

## Discussion:

Spatial distribution of spring Chinook spawners has increased as a result of acclimation site location, salmon homing fidelity and more fully seeding preferred spawning habitats (Dittman et al. 2010). Redd surveys in the Teanaway River conducted annually by Yakama Nation staff since 1981 demonstrate the benefits of reintroducing salmonids into underutilized habitat (Figure 14). The Jack Creek acclimation site began releasing CESRF spring chinook in 2000, with the first age-4 females returning from these releases in 2002. Redd counts in this tributary have increased from a pre-supplementation average of 3 redds per year to a post supplementation average of 63 redds per year. The proportion of natural-origin carcasses increased from less than one percent in 2002 (when CESRF fish first returned to the natural spawning grounds) to $42 \%$ in 2006 when the progeny of the 110 redds produced in 2002 (virtually $100 \%$ of which were produced by CESRForigin fish) returned. These data clearly indicate that naturally-spawning CESRF spring Chinook were successful in returning natural-origin adults back to the Teanaway River. However, redd counts in the Teanaway River remain at or below pre-supplementation levels in some years indicating that habitat factors (primarily low late-summer and fall season flows) continue to deter returning fish and these fish are likely spawning in nearby mainstem and tributary reaches more conducive to survival of progeny (Fast et al. 2015).

Fall Chinook redd distribution in the Yakima River Basin appears to be experiencing a major transition in recent years. Historical redd survey data indicates that a substantial number of fall Chinook spawned below Prosser Dam in the lower Yakima River. However, from 2003-present, an average of approximately 80 percent (range 62 to 90 percent) of surveyed fall Chinook redds have been located above Prosser Dam (Figure 16). Biologists and habitat experts in the subbasin at least partially attribute this change in spawning distribution to the invasion of water stargrass (see Wise et al. 2009) in the lower 43 miles of the Yakima River. With the reintroduction of summer run Chinook, the Yakama Nation is expanding the distribution of summer/fall run Chinook spawners and redds into the middle reaches of the Yakima Basin between the town of Wapato upstream to the confluence with the Tieton River in the Naches subbasin and to Roza Dam in the Upper Yakima subbasin (Figures 1 and 15; Yakama Nation 2012). Figure 15 indicates a good distribution of reintroduced summer-run spawners into the intended habitats above Parker Dam in 2017, primarily age-4 fish returning from subyearling releases in 2014. This is the fourth year of substantial natural summer-run Chinook spawning in these habitats in over 40 years.

Coho redd counts and spawner distribution have increased substantially since reintroduction efforts began (Table 14 and Figure 17). Many redds in the mainstem were located intermixed with fall chinook redds, tucked under cut banks or were
found in side channels. Tributary redd enumeration and identification continues to be accurate due to the fall low water levels, improving interagency cooperation, and relatively good weather. One of the overall goals during the present implementation phase (Phase II) of the coho program is to evaluate the transition of redds from the mainstem river into historic tributaries. With the beginning of Phase II of the Coho Program we observed large increases in tributary spawning, with an annual average exceeding 200 redds counted in tributaries since 2004 (Table 14). Although, there were large numbers of potential spawners in 2014 ( $\sim 9,000$ females), river conditions were very unfavorable for finding redds. Winter anchor ice in early December kept surveys to a minimum. This was followed by winter freshets that reduced visibility in the Naches River to the point where visibility was near zero. However, the stability of low water conditions in 2015 might have contributed to good survival of coho eggs from the 2014-2015 spawning season. The 2017 redd count rose significantly from the two prior years to a total of 305 (Table 14). River conditions were much better than previous years for successful spawner surveys. Coho continue to volunteer into many tributaries, and the fidelity of adults from summer parr plants has shown good results. The tributary redd counts we observed in Cowiche Creek in 2014 were very encouraging and likely contributed to the 51 redds we counted in Cowiche Creek in 2017. The study in Taneum Creek was set up to test reintroduction and interactions (Temple et al. 2012); it was not set up for full reintroduction. With implementation of the Coho Master Plan, we expect to double adult out plant numbers, increase escapement into Taneum Creek, and fully seed the available habitat.

## Status and Trend of Diversity Metrics

## Methods:

Diversity metrics collected for the Cle Elum Supplementation and Research Facility spring Chinook program in the Upper Yakima River include parameters relating to: eggs (e.g., egg size, KD at emergence, emergence timing, etc.), juveniles (growth and survival, migration timing, fish health, etc.), and adults (size at age, sex composition, migration timing, etc.). Methods for monitoring the spring Chinook program were documented in: the YKFP Monitoring Plan (Busack et al. 1997), the project's "Supplementation Monitoring Plan" (Chapter 7 in 2005 annual report on project genetic studies), and numerous manuscripts in the published literature (see Results and References).

Diversity metrics for returning adult summer/fall Chinook and coho collected at the Prosser Dam denil fish trap include sex ratios, lengths, and weights (monitoringresources.org methods 454, 1454, 1548, 1549, 1551, 4008, 4041).

## Results and Discussion:

A detailed presentation of current results for the spring Chinook monitoring program (YN-collected data) are included in Appendix B of this report and are discussed in greater detail in the annual report(s) for WDFW-companion project 1995-064-25. Generally, we have detected small, but significant differences between hatchery- and natural-origin fish in some juvenile and adult traits. Results in the published literature include: Busack et al. (2007), Knudsen et al. (2006, 2008), Larsen et al. (2004, 2006, 2010, 2013), and Pearsons et al. (2009).

Sex ratios, lengths, and weight data for fall Chinook and coho salmon sampled at the Prosser denil adult sampling facility from 2001-present are presented in Tables 16-19. In addition, preliminary results of some diversity metrics relating to the effort to reestablish a natural spawning coho population in the Yakima Basin were published in Bosch et al. (2007). That study observed divergence in some diversity traits between hatchery- and natural-origin fish suggesting that some re-naturalization can be detected in just a few generations after outplanting of hatchery-origin fish in the wild.

## Habitat Monitoring

While the majority of YKFP habitat activities in the Yakima Basin are addressed in a separate project (1997-051-00), we are monitoring stream sediment loads associated
with the operation of dams and other anthropogenic factors (e.g. logging, agriculture and road building) under this contract as sediment loads can affect survival of salmonids (see description and references here).

## Status and Trend of Fine Sediment

Methods: Representative gravel samples (McNiel core samples, monitoring resources 1504) were collected from various reaches in the Little Naches and Upper Yakima Rivers in the fall of 2017. Each sample was analyzed to estimate the percentage of fine or small particles present $(<0.85 \mathrm{~mm})$. The Washington State Timber, Fish, and Wildlife program established guidelines that specify the impacts that estimated sedimentation levels can have on salmonid egg-to-smolt survival. These impact guidelines will inform future analyses of "extrinsic" factors on natural production in the Yakima Basin.

## Results and Discussion:

## Little Naches

A total of 108 McNiel core samples were collected and processed from 9 spawning reaches in the Little Naches drainage this past year. Pyramid Creek has not been sampled since 2009 when the main road going into this reach was decommissioned. Other means to access this sampling site is needed. With this year's monitoring work, the data set for the Little Naches drainage now covers a time period of 33 years for the two historical reaches, and 26 years for the expanded sampling area that includes several tributary streams.

The average percent fine sediment less than 0.85 mm for the entire Little Naches drainage in 2017 was $10.7 \%$ which continued the increase observed since a low in 2015, but is still below the watershed average observed every year from 19922007 (Figure 18). The overall trend remains downward and similar trends can be seen when looking at individual reach conditions over the longer term monitoring period since 1992.

The overall average fine sediment found in spawning substrate remains relatively low and should lessen mortality on incubating eggs and alevins. The reduced rate of fine sediment found can be partially attributed to less anthropogenic disturbance occurring in the watershed in recent years, other than recreational activity. Timber harvest activity and road building has been minimal for several years. Landowners have also improved roads and trails to reduce sediment delivery. Further, enhanced stream protection measures have been instituted through the Northwest Forest Plan and the Central Cascades Habitat Conservation Plan for over 20 years. These factors have likely helped reduce fine sediment inputs to the stream
system. However recreational activity, such as dispersed camping sites and off-road vehicle use near streams, continues to be a concern. Sediment delivery, bank erosion, and loss of riparian vegetation from recreational use have been observed in some localized areas.

Figure 18. Overall Fine Sediment ( $<0.85 \mathrm{~mm}$ ) Trends with $95 \%$ confidence bounds in the Little Naches River Drainage, 1992-2017.

## South Fork Tieton

One reach on the South Fork Tieton River (in the vicinity of Minnie Meadows) has been sampled in the past by the U.S. Forest Service. To the best of our knowledge this reach has not been sampled since 2015 . This stream reach typically receives significant bull trout spawning activity and the monitoring efforts provide valuable information on their spawning conditions. Average fine sediment in this reach was $8.9 \%$ in 2015 , matching the previous low observed in 1999 , and is well below the mean for sediment levels for the 17 years that were sampled (Figure 19).

## Upper Yakima

A total of 56 samples were collected and processed from the Upper Yakima River drainage this past year (5 reaches, 12 samples from each reach except Elk Meadows which only had 8 samples). The same reaches (Stampede Pass, Easton,

Camelot to Ensign Ranch, Elk Meadows, and Cle Elum) have been sampled annually for the past 21 years. The 21-year trend in average percent fine sediment less than 0.85 mm for the combined Upper Yakima drainage continues downward, with observed fine sediments in 2017 very similar to the average observed since 2009 (Figure 20).

Figure 19. Fine Sediment Trends in the South Fork Tieton River, 1999-2015. Note: Data for 2007 were collected from only 1 Riffle. Data courtesy of U.S. Forest Service.

Figure 20. Overall average percent fine sediment ( $<\mathbf{0 . 8 5} \mathrm{mm}$ ) in spawning gravels of the Upper Yakima River, 1997-2017.

## Summary

We continue to observe a general decreasing trend in average fine sediment levels in the Little Naches and Upper Yakima drainages. These low rates of fine sediment should be conducive for egg and alevin survival and should favor salmonid spawning success.

The results of the USFS sampling in the South Fork Tieton River have also been low over a 17 -year sampling period. These conditions should be favorable for early life history survival of bull trout.

Detailed field data including additional tables and graphs for samples collected in the upper Yakima and Naches basins can be obtained from Jim Matthews, fisheries biologist for the Yakama Nation (matj@yakamafish-nsn.gov).

## Harvest Monitoring

## Marine and Mainstem Columbia Fisheries

Methods: We evaluated recoveries of coded-wire tags (CWTs) and PIT tags in out-of-basin fisheries using queries of regional mark information system (RMIS) and PIT Tag Information System (PTAGIS) databases. We coordinated with agencies responsible for harvest management (WDFW, ODFW, USFWS, CRITFC, etc.) to estimate the harvest of target stocks. We reviewed reports produced annually by the Pacific Fisheries Management Council (marine) and the U.S. v Oregon Technical Advisory Committee (mainstem Columbia) to evaluate estimated harvest or exploitation rates on comparable stocks in these fisheries.

For spring Chinook, additional information was employed that is not readily available for fall Chinook and coho. Standard run reconstruction techniques (Appendix B) were employed to derive estimates of harvest from the Columbia River mouth to the Yakima River mouth for spring Chinook. Data from databases maintained by the U.S. v Oregon Technical Advisory Committee were used to obtain harvest rate estimates downstream of the Yakima River for the aggregate Yakima River spring Chinook population and to estimate passage losses from Bonneville through McNary reservoirs. These data, combined with the Prosser Dam counts and estimated harvest below Prosser, were used to derive a Columbia River mouth run size estimate and Columbia River mainstem harvest estimate for Yakima spring Chinook.

## Results:

Table 20. Marine and freshwater recoveries of CWTs from brood year 1997-2012 releases of spring Chinook from the CESRF as reported to the Regional Mark Information System (RMIS) 22 Nov 2017.

| Brood <br> Year | Observed CWT Recoveries |  | Expanded CWT Recoveries |  |  |  |
| :---: | ---: | ---: | ---: | ---: | ---: | ---: |

1. Preliminary.

Figure 21. Distribution of coded-wire tag recoveries of Yakima Basin summer/fall run Chinook releases in marine, mainstem Columbia River, and Yakima Basin fisheries. Data retrieved from the regional mark information system (RMIS) for brood year 1997-2007 recoveries.

Recovery data for Yakima River-origin coho are presently limited because few fish have been coded wire-tagged until recent years. We will continue to collect and analyze CWT-recovery data from regional databases and will report this information in the future. 'All H Analyzer' (AHA) modeling for Master Planning purposes assumed that natural- and hatchery-origin Yakima River coho have an exploitation rate of approximately 40 and 60 percent, respectively (Yakama Nation 2012). These estimates include coho caught in marine, Columbia River and Yakima River fisheries.

## Discussion:

Based on available CWT information, harvest managers have long assumed that Columbia River spring Chinook are not harvested in any abundance in marine fisheries as their ocean migration does not generally overlap either spatially or temporally with the occurrence of marine fisheries (TAC 1997). Harvest recoveries of CESRF spring Chinook as reported to RMIS to date appear to confirm this, as marine harvest apparently accounts for only about $0-3 \%$ of the total harvest of Yakima Basin spring Chinook (Table 20). Adult returns of spring Chinook from the CESRF appear to be making substantial contributions to Columbia Basin fisheries (Table 21).

Yakima Basin summer/fall Chinook are harvested in marine fisheries from Alaska to southern Oregon, and in Columbia River fisheries from the mouth to the Hanford Reach (Figure 21). Approximately 71\% of harvest recoveries from Yakima Basin fall Chinook releases for brood years 1997-2007 occurred in marine (44\%) and mainstem

Columbia ( $27 \%$ ) fisheries. Out-of-basin harvest rates have not been estimated specifically for Yakima Basin summer/fall run Chinook, but the 1982-89 brood year average ocean fisheries exploitation rate for mid-Columbia River summer/fall Chinook was $39 \%$, with a total exploitation rate of $68 \%$ estimated for the same years (PSC 1994). Chapman et al. (1994) estimated that the 1975-87 brood year mean exploitation rate for fall Chinook released from Priest Rapids Hatchery was $64 \%$. Harvest rates of these stocks in U.S. fisheries since the mid-1990s have been reduced due to Endangered Species Act (ESA) management concerns as these stocks are intermixed with ESA-listed Snake River fall Chinook populations (NMFS 1999a-d and $2000 \mathrm{a}-\mathrm{c}$ ). It is assumed that Yakima River summer/fall run Chinook are harvested at the same rate in these fisheries as other mid-Columbia River summer/fall Chinook stocks.

## Yakima Subbasin Fisheries

Methods: The two co-managers, Yakama Nation and WDFW, are responsible for monitoring their respective fisheries in the Yakima River. Each agency employs fish monitors dedicated to creel surveys and/or fisher interviews at the most utilized fishing locations and/or boat ramps. From these surveys, standard techniques are employed to expand fishery sample data for total effort and open areas and times to derive total harvest estimates. Fish are interrogated for various marks. Methods are consistent with monitoringresources.org methods 404 and 960.

## Results:

## Discussion:

Adult returns of spring Chinook from the CESRF have substantially increased fishing opportunity for all fishers in the Yakima Basin (Table 22) and returned recreational fisheries to the Basin after a 40 -year absence. This has contributed to improved relationships between all the Basin's stakeholders and increased opportunities for collaboration.

Recreational fishers enjoy a successful annual fall Chinook fishery situated primarily near the mouth of the Yakima River (Table 23). Tribal fishers harvest a substantial, but unquantified number of Yakima Basin-destined fall Chinook (Figure 21) and coho in commercial gillnet fisheries in the Zone 6 fishing area. Because of the quantity and relatively higher quality of fall Chinook and coho available to tribal fishers in Zone 6 Columbia and Klickitat River fisheries, Yakima River tribal harvest is typically at or near zero even though regulations allowing fall season fisheries in the Yakima River are propagated annually by the Yakama Nation.

## Hatchery Research

## Effect of Artificial Production on the Viability of Natural Fish Populations

WDFW is addressing some critical uncertainties (see Columbia River Basin Research Plan and Critical Uncertainties for the Columbia River Basin Fish and Wildlife Program) related to genetic and ecological interactions under project 1995-064-25. We are working jointly with WDFW to address the following additional fish propagation uncertainties:
1.2. Can hatchery production programs meet adult production and harvest goals (integrated and segregated) while protecting naturally spawning populations?
1.4. What is the magnitude of any demographic benefit or detriment to the production of natural-origin juveniles and adults from natural spawning of hatchery-origin supplementation adults?
1.5. What are the range, magnitude and rates of change of natural spawning fitness of integrated (supplemented) populations, and how are these related to management rules including the proportion of hatchery fish permitted on the spawning grounds, and the proportion of natural origin adults in the hatchery broodstock?

## Methods:

The YKFP began a spring Chinook salmon hatchery program at the CESRF near Cle Elum on the upper Yakima River (river kilometer 297, measuring from the confluence with the Columbia River; Figures 1 and 22) in 1997. This program is a supplementation effort targeting the upper Yakima River population and is designed to test whether artificial propagation can be used to increase natural production and harvest opportunities while limiting ecological and genetic impacts (RASP 1992). It is an integrated hatchery program (Mobrand et al. 2005) because only natural-origin brood-stock are used and returning hatchery-origin adults are allowed to spawn in the wild. The program employs "best practice" hatchery management principles (see Cuenco et al. 1993, Mobrand et al. 2005) including reduced pond densities, strict disease management protocols, random brood-stock selection, and factorial mating (Busack and Knudsen 2007) to maximize effective population size. Fish are reared at the central facility, but released from three acclimation sites located near the central facility at: Easton approximately 25 km upstream of the central facility, Clark Flat about 25 km downstream of the central facility, and Jack Creek about 12 km upstream from the Teanaway River's confluence with the Yakima River (Figure 22). The CESRF collected its first spring Chinook brood-stock in 1997, released its first fish in 1999, and age-4 adults have been returning since 2001. The first generation of offspring of CESRF and wild fish spawning in the wild returned as adults in 2005. The program uses the adjacent, un-supplemented Naches River population as an environmental and wild control system.

To evaluate demographic benefits for spring Chinook, we compared redd count and natural-origin adult return data for the supplemented Upper Yakima and unsupplemented (control) Naches populations using a Before/After Control/Impact (BACI) analysis (Stewart-Oaten et al. 1986; Smith et al. 1993). For redd counts, the before period was defined as 1981 to 2000 and the after period as 2001 to present (hatchery-origin age-4 adults first returned to integrate with natural-origin fish on the natural spawning grounds in 2001). The first natural-origin returns of age-4 fish from these integrated population redds did not occur until 2005, so the pre- and postsupplementation (before/after) periods for natural-origin return evaluation were defined as 1982 to 2004 and 2005 to present, respectively. The spring Chinook findings described below were published in Fast et al. (2015). We are working with WDFW to incorporate additional out-of-basin control populations in this evaluation and these results will be considered for publication at a later date.

To evaluate fitness parameters for an integrated spring Chinook population, we used methods described in Knudsen et al. (2008), Schroder et al. (2008, 2010, and 2012) and Waters et al. (2015; discussed further below under Hatchery Reform). For coho,
we conducted preliminary evaluation of both demographic benefits and some fitness parameters using methods described in Bosch et al. (2007).

Figure 22. Map of the Yakima River Basin, Cle Elum Supplementation and Research Facility (CESRF) locations, and timeline of the spring Chinook supplementation program.

## Results:

Figure 23. Spring Chinook redd counts in the supplemented Upper Yakima (red bar) relative to the unsupplemented Naches (control; blue bar) for the pre- (1981-2000) and post-supplementation (2001-2017) periods.

Figure 24. Natural-Origin returns of Spring Chinook in the supplemented Upper Yakima (blue bar) relative to the un-supplemented Naches (control; yellow bar) for the pre- (1982-2004) and post-supplementation (2005-2017) periods.

## Discussion:

Supplementation has increased spring Chinook redd abundance in the Upper Yakima relative to the Naches control system (Figure 23). Redd counts in the postsupplementation period (2001-2017) increased in the supplemented Upper Yakima ( $+99 \%$; $\mathrm{P}=0.008$ ) but the change observed in the un-supplemented Naches control system relative to the pre-supplementation period (1981-2000) was not significant ( $+37 \%$; $\mathrm{P}=0.126$ ). As noted above, spatial distribution of spring Chinook has also increased as a result of supplementation with dramatic increases in redd abundance observed in the Teanaway River (Figure 14) in some years.

Changes in mean natural-origin return abundance in the post-supplementation period (2005-2017) relative to the pre-supplementation period (1982-2004) were not significant in either the supplemented upper Yakima River ( $+9.7 \%$; $\mathrm{P}=0.73$; Figure 24) or the unsupplemented Naches River system ( $-14.7 \%$; $\mathrm{P}=0.58$; Figure 24). We have already noted that limiting factors appear to be inhibiting natural productivity (see status and trend of adult productivity) throughout the Yakima Basin. It may also be that the post-supplementation time period is not yet long enough to detect a significant change in this natural production parameter. Given the relatively short post-supplementation time series, these findings are preliminary. We will continue to incorporate additional years of data and out-of-basin control populations into this evaluation and publish more complete findings at a later date.

With respect to spring Chinook fitness parameters we found the following. The relationships between reproductive traits and body length were not significantly altered by a single generation of hatchery exposure. However, because hatchery females had smaller body sizes, the distributions of linked traits, such as total gamete mass and fecundity, differed by as much as 0.6 SD , probably resulting in some fitness loss. Our data support the idea that a single generation of state-of-the-art conservation hatchery propagation can produce fish with reproductive traits similar to those of wild fish, given comparable body size (Knudsen et al. 2008). No differences were detected in the egg deposition rates of wild and hatchery origin females, but pedigree assignments based on microsatellite DNA showed that the eggs deposited by wild females survived to the fry stage at a $5.6 \%$ higher rate than those spawned by hatchery-origin females (Schroder et al. 2008). Behavior and breeding success of wild and hatchery-origin males were found to be comparable (Schroder et al. 2010). Large anadromous males produced $89 \%$, jacks $3 \%$, yearling precocious $7 \%$, and sub-yearling precocious $1 \%$ of the fry in our tests suggesting that large anadromous males generate most of the fry in natural settings when half or more of the males present on a spawning ground use this life history strategy (Schroder et al 2012). For additional
detail on Spring Chinook findings, see Fast et al. (2015). Finally, in addition to the relative reproductive success (RRS) results reported by Schroder et al. (2008 and 2010) for artificial spawning channel studies, we are also working with our project collaborators at WDFW and CRITFC to evaluate RRS for all integrated hatchery- and natural-origin spawners above Roza Dam for brood years 2007-2011 (see https://www.cbfish.org/Document.mvc/Viewer/P159280 for the latest progress report on this project). We expect to complete genotyping for this work this year and hope to publish findings by 2020. Preliminary results for just the 2007 brood year were reported by CRITFC at the 2017 Science and Management conference and are encouraging: a demographic boost from the CESRF program of 2.2 X with only jacks showing statistically significant differences in RRS between hatchery-reared and natural-origin fish spawning naturally.

The YKFP is presently studying the release of over 1.0 million coho smolts annually from acclimation sites in the Naches and Upper Yakima subbasins. These fish are a combination of in-basin production from brood-stock collected in the vicinity of Prosser Dam plus out-of-basin stock generally reared at Willard or Eagle Creek National Fish Hatcheries and moved to the Yakima Subbasin for final rearing and release. Monitoring of these efforts to re-introduce a sustainable, naturally spawning coho population in the Yakima Basin have indicated that coho returns averaged over 6,000 fish from 1997-2017 (an order of magnitude improvement from the average for years prior to the project) including estimated returns of wild/natural coho averaging over 900 fish annually since 2001 (Figure 4). Coho re-introduction research has demonstrated that hatchery-origin coho, with a legacy of as many as 10 to 30 generations of hatchery-influence, can reestablish a naturalized population after as few as 3 to 5 generations of outplanting in the wild (Bosch et al. 2007). The project is working to further develop a locally adapted brood-stock and to establish specific release sites and strategies that optimize natural reproduction and survival.

## Effectiveness of Hatchery Reform

Hatcheries have long been a part of the fisheries landscape in the Pacific Northwest with programs originally designed to provide abundant returns for harvest in river ecosystems that were becoming increasingly exploited to serve human needs (Lichatowich 1999). Historically, hatchery programs were designed to release a specified number of juveniles from a central facility, and adult survivors, after providing many fish for harvest during their marine and freshwater migrations, would return to swim-in ladders and adult holding ponds at that same facility to spawn successive generations. Over the past two decades or more, such programs have been the subject of much scientific study regarding risks, such as domestication, they pose to natural populations if these fish spawn in the wild.

The concepts of supplementation and hatchery reform, where hatchery programs could be (re)designed to serve conservation as well as harvest purposes, first began to appear in regional discussions and the literature in the late 1980s and early 1990s (e.g, RASP 1992; Cuenco et al. 1993). In Mobrand et al. (2005) and Paquet et al. (2011), the Hatchery Scientific Review Group (HSRG) described in more scientific detail several principles that should guide integrated (conservation-oriented) hatchery programs which purposefully allow fish to spawn in the wild (note that virtually all of the HSRG recommendations were designed into the integrated CESRF program described above). The HSRG reports also recommended that traditional, harvestoriented hatchery programs should be segregated as much as possible from natural populations to minimize risks by limiting the number of returning fish that escape to natural spawning grounds.

YKFP efforts to monitor and evaluate hatchery reform focus on the CESRF spring Chinook program which was designed explicitly for this purpose from its inception (BPA 1996). To the extent that is practical, we will evaluate similar metrics for the summer/fall run Chinook and coho programs and publish those results in future reports as the Master Plan (Yakama Nation 2012) is implemented and the programs mature over time.

In addition to the integrated (supplementation-S) hatchery program described above for the CESRF, this facility also introduced a segregated "hatchery control" (HC) program in 2002 as recommended by independent scientific review. To protect the integrity of the integrated program evaluation described above, returning HC line fish were either harvested or trapped and removed at the Roza Adult Monitoring Facility (RAMF); no HC line fish were allowed to escape to the spawning grounds (determination of fish origin was based on a differential marking strategy for $S$ and HC fish; unmarked fish were presumed wild). CESRF-project scientists hypothesized that HC-line fish, which use only returning hatchery-origin fish as brood source, would increasingly diverge in phenotypic and genetic characteristics from wild (WC or wild control) fish with increasing generations of hatchery influence, whereas S-line fish, which use only wild or natural-origin fish for brood source, would remain relatively close in characteristics to wild fish (Figure 25). These hypothetical outcomes were based on hatchery reform theory which suggests that, by using only wild or natural-origin parents to spawn successive generations of fish in the hatchery environment, mean fitness of an integrated population in the natural environment can be maintained relatively close to that of a wild population (Mobrand et al. 2005).

# DOMIESTICATION 

 HYPOTHETICAL OUTCOMES

TIME

Figure 25. Hypothetical outcomes of trait divergence (domestication effects) over time for a segregated (hatchery-control or HC) line of fish, compared to an integrated (supplementation or $S$ ) line of fish and a wild (wild-control or WC) line of fish (D. Fast, Yakama Nation).

This section reports on our efforts to evaluate the effectiveness of hatchery reform measures implemented in the CESRF program.

## Methods:

Methods for enumerating natural- and CESRF-origin fish at Roza Dam were described above (Status and Trend of adult abundance) and in Knudsen et al. (2006). Methods for evaluating genetic differentiation between the wild founding, integrated, and segregated populations at the CESRF were described in Waters et al. (2015).

A recently developed parameter to monitor the mean fitness of an integrated population in the natural environment is called Proportionate Natural Influence (PNI). PNI is an approximation of the rate of gene flow between the natural environment and the hatchery environment (Busack et al. 2008). The equation describing PNI is

$$
\mathrm{PNI}=\frac{\mathrm{pNOB}}{\mathrm{pNOB}+\mathrm{pHOS}}
$$

where pNOB is the proportion of natural-origin brood-stock and pHOS is the proportion of hatchery-origin spawners. We evaluated PNI for the CESRF program using a pNOB value of 1.0 as only natural-origin fish were used for the integrated program's broodstock.

## Results and Discussion:

For CESRF integrated program return years 2001-2017, PNI averaged $66 \%$ while pHOS averaged $53.5 \%$ (Table 25). As stated in the introduction to this report and in the final Environmental Impact Statement for the Yakima Fisheries Project (BPA 1996), one of the explicit purposes of the project is to test the assumption that new artificial propagation or hatchery reform techniques (Cuenco et al. 1993, Mobrand et al. 2005) can be used to increase natural production without causing significant impacts to existing natural populations. Therefore it has always been the intent of this project to purposely allow integrated hatchery-origin fish to escape to the natural spawning grounds, i.e., we intentionally maintained a relatively high pHOS rate. Even with a high pHOS relative to recommendations, PNI for the CESRF integrated program remained in the "low hatchery influence for conservation of natural populations" category described by the HSRG (Paquet et al. 2011).

The project will continue to monitor PNI considering factors such as: policy input regarding controlling the number and types of fish allowed to escape to natural spawning areas, meeting overall production goals of the project, guidance from the literature relative to percentage of hatchery fish on the spawning grounds with fitness loss, considerations about what risk is acceptable in a project designed to evaluate impacts from that risk, and the numerous risk containment measures already in place in the project. The State of Washington is using mark-selective fisheries in the lower Columbia River and, when possible, in the lower Yakima River in part as a tool to manage escapement proportions. In 2011, the project implemented an effort to transfer some returning hatchery-origin CESRF adults from Roza Dam to Lake Cle Elum for the purpose of returning marine derived nutrients and salmon to the watersheds that feed the lake. These measures will also increase PNI in the major spawning areas of the Upper Yakima Basin. Additional adaptive management measures will be considered when and if monitoring and evaluation indicates a need.

1. Proportionate Natural Influence equals Proportion Natural-Origin Brood-stock (PNOB; 1.0 as only NoR fish are used for supplementation line brood-stock) divided by PNOB plus Proportion Hatchery-Origin Spawners (PHOS).
2. This is a rough estimate since Roza counts are not available for 1991.
3. For NoR columns, mean of 1997-present values. For all other columns, mean of 2001-present values.

Both the CESRF integrated and segregated programs have now proceeded for several generations and we can evaluate actual outcomes relative to the hypothetical outcomes given in Figure 25 above. Results were presented in Waters et al. (2015) and empirically demonstrate that using managed gene flow (i.e, using only naturalorigin fish for brood stock) reduced genetic divergence over time in the CESRF
integrated (S-line) fish compared to the segregated (HC-line; hatchery-origin parents) fish (Figure 26). The actual results are remarkably consistent with the projected outcomes in Figure 25 demonstrating that there is considerable merit to the concepts behind hatchery reform. While some detractors of hatchery supplementation choose to highlight the differences the CESRF program has found between hatchery and natural-origin fish such as those documented in Knudsen et al. (2006 and 2008), it is important to note that integrated hatchery-origin fish were never expected to be identical to wild fish (Figure 24), but rather similar enough to increase demographic abundance of natural spawners while minimizing risk, which is exactly what the results to date for this project demonstrate (Fast et al. 2015; Koch et al. 2017). Additional evaluation is required before definitive answers to key biological cost and benefit questions relative to using this type of management over the long-term will be known with scientific certainty (Fraser 2008). The YKFP is continuing its collaboration with University of Washington and NOAA scientists to further evaluate and associate genetic divergence results from Waters et al. (2015) with the phenotypic trait analyses in Knudsen et al. (2006 and 2008).

Discriminant Analysis of Principal Components

Figure 26. Estimated genetic divergence (variation) for integrated (INT blue), segregated (SEG red), and wild founder (black) spring Chinook in the CESRF program after 4 parental-generations of the hatchery program ( $\mathrm{P} 1=1998$, $\mathrm{F} 1=2002, \mathrm{~F} 2=2006, \mathrm{~F} 3=2010$, F4=2014; updated from Figure 4 in Waters et al. 2015).

Additional information and results from the CESRF program are provided in Appendix B and in Fast et al. (2015).

## Predation Management and Predator Control

## Avian Predation Index

Avian predators are capable of significantly depressing smolt production. The loss of wild spring Chinook salmon juveniles to various types of avian predators has long been suspected as a significant constraint on production and could limit the success of supplementation. Therefore, a long-standing objective of the YKFP has been to monitor, evaluate, and index the impact of avian predation on annual salmon and steelhead smolt production in the Yakima Subbasin. Accurate methods of indexing avian predation across years have been developed.

## Methods:

## River Reach Surveys

The spring river surveys included nine river reaches (Table 26) and were generally consistent with avian point count methods described in monitoringmethods.org method 1151 . The surveys account for coverage of approximately $40 \%$ of the total length of the Yakima River.

Table 26. Avian predation river reach survey start and end locations and total reach length.

| Name | Start | End | Length (km) |
| :--- | :--- | :--- | :--- |
| Easton | Easton Acclimation Site | Bridge | 29.3 |
| Cle Elum | South Cle Elum Bridge | Thorp Hwy Bridge | 28.3 |
| Canyon | Ringer Road | Lmuma or Roza Recreation Site | 20.8 or 29.8 |
| Selah Section | Harrison Rd Bridge | Harlan Landing Park | 6.42 |
| Gap to gap | Harlan Landing Park | Hwy 8 Bridge | 15.85 |
| Parker | USlow Parker Dam US Hwy 97 | Granger Bridge Ave Hwy Bridge | 20.3 |
| Zillah | Chandler Canal Power Plant | Benton City Bridge | 16.0 |
| Benton | Vangie | 1.6 km above Twin Bridges | Van Giesen St Hwy Bridge |

All river reach surveys were conducted by a two-person team from a 16 foot drift boat or 12 foot raft. Surveys began between 8:00 am and 9:00 am and lasted between 2 to 6 hours depending upon the length of the reach and the water level. All surveys
were conducted while actively rowing the drift boat or raft downstream to decrease the interval of time required to traverse the reach. One person rowed the boat while the other person recorded piscivorous birds encountered.

All birds detected visually or aurally were recorded, including time of observation, species, and sex and age if distinguishable. Leica 10x42 binoculars were used to help observe birds. All piscivorous birds encountered on the river were recorded at the point of initial observation. Most birds observed were only mildly disturbed by the presence of the survey boat and were quickly passed. Navigation of the survey boat to the opposite side of the river away from encountered birds minimized escape behaviors. If the bird attempted to escape from the survey boat by moving down river a note was made that the bird was being pushed. Birds being pushed were usually kept in sight until passed by the survey boat. If the bird being pushed down river moved out of sight of the survey personnel, a note was made, and the next bird of the same species/age/sex to be encountered within the next 1000 meters of river was assumed to be the pushed bird. If a bird of the same species/age/sex was not encountered in the subsequent 1000 meters, the bird was assumed to have departed the river or passed the survey boat without detection, and the next identification of a bird of the same species/age/sex was recorded as a new observation.

## Acclimation Site Surveys

Three Spring Chinook acclimation sites in upper Yakima River (Clark Flat, Jack Creek, and Easton) and one Coho site (JD Holmes) were surveyed for piscivorous birds from 2004 through 2017 (Figure 1). Surveys were conducted between January 23 and June 10, though dates varied for each site. Three surveys were conducted at the Spring Chinook sites each day, at 8:00 am, 12:00 noon, and 4:00 pm. The Coho site was surveyed once or twice on days hatchery personnel were feeding smolts. Surveys were conducted on foot. All piscivorous birds within the acclimation facility, along the length of the artificial acclimation stream, and 50 meters above and 150 meters below the acclimation stream outlet, into the main stem of the Yakima River or its tributaries, were recorded.

## Salmon PIT Tag Surveys at Great Blue Heron Rookeries

A Passive Integrated Transponder (PIT) tag reader was used to survey for PIT tags deposited in various Yakima River Great Blue Heron Rookeries (Figure 27). Methods were generally consistent with Evans and Hostetter (2012) and with monitoringmethods.org method 255.

Areas surveyed included: Selah, Toppenish Creek, Buena, Wapato Wildlife area, Grandview, and Satus. Based on the salmon tags found at these sites consumption could be assigned to piscivorous fish: American White Pelicans, Double Crested Cormorants, and the Great Blue Herons. Predation assignment was strictly by observation. For example, the Chandler Bypass has been heavily used by pelicans since 2003 while the Selah Heronry supports herons and sometimes cormorants.

Figure 27. Map of Yakima Basin Heron Rookeries.
PIT Tag surveys were conducted using the Portable Transceiver System: PTS Model FS2001F-ISO from Biomark. The transceiver is designed to scan for PIT tags and identify them by their given code. A Garmin GPS unit was used to map rookeries along with survey plots or points. Additional equipment included the use of camouflage to limit disturbance for bird nest identification and counts.

Rookeries were surveyed to determine total rookery numbers and Great Blue Heron population numbers via jet boat, plane, and foot. Rookeries were surveyed in the spring and summer for population numbers using binoculars; rookeries were not
entered for fear of causing bird abandonment. Once birds had fledged, rookeries were cleared of debris under nests to scan for defecated/regurgitated PIT tags.

The objectives for the study were:

- Identify all Rookeries in the Yakima Basin
- Survey populations during nesting
- Estimate detection efficiencies by seeding PIT Tags
- Clear PIT Tag deposit areas after fledging
- Survey for PIT Tags post fledge and after flooding
- Remove PIT Tags (tag collision causes interference)
- Conduct aerial flights and river surveys to monitor populations

## Results and Discussion:

River Reach Surveys

Figure 28. Upper Yakima piscivorous birds per kilometer (Common Merganser-COME, Bald Eagle-BAEA, and Osprey-OSPR).

Figure 29. Lower Yakima piscivorous birds per kilometer (American White Pelican-AWPE, Double Crested Cormorant-DCCO, and Gulls-GULL).
Thirteen different piscivorous bird species were observed on the Yakima River. These included: American White Pelican, Bald Eagle, Black-crowned Night Heron, Belted Kingfisher, Caspian Tern, Common Merganser, Double-crested Cormorant, Forster's Tern, Great Egret, Great Blue Heron, Gull species, Hooded Merganser, and Osprey. These same 13 species were observed in most survey years. Graph data for river reach surveys represents a combined view of the upper Yakima River (surveys above Wapato Dam; Figure 28) and the lower Yakima River (surveys below Wapato Dam; Figure 29). The three top bird predators within these bisected areas were chosen for graph representation.

Osprey, Great Blue Heron, and Belted Kingfisher were the only species found on all six reaches in the spring, and Common Mergansers were observed on all reaches except the Vangie reach. Common Mergansers were most abundant in the upper reaches of the river (Easton and Cle Elum reaches) which was the case in all years surveyed (Figure 28).

Gull numbers in the lower Yakima River decreased in 2016 and this trend continued into 2017, reversing the rise observed in the prior two years (Figure 29). Double Crested Cormorant numbers surveyed remained consistent with prior years. This species remains a concern due to takeover of Great Blue Heron Rookeries in various areas along the Yakima River. Monitoring of the Double Crested Cormorant on the river and in rookeries will be a priority in upcoming years as the Army Corp of Engineers culls and removes breeding habitat at the estuary of the Columbia River in
efforts to reduce juvenile salmon predation (USACE 2014). These actions may result in displacement and searching out of new habitat for the Cormorants and lead to impacts on salmon in other rivers and basins. The American White Pelican numbers remain consistently high in the lower Yakima River. In the Yakima River, pelicans can be seen in groups of over 100 in the Wapato Reach of the river along the borders of the Yakama Indian Reservation.

## Acclimation Sites Surveys

Figure 30. Average number of Belted King Fishers observed per day at the Easton spring Chinook acclimation site between 2005 and 2017 when fish were present.

Figure 31. Average number of Common Mergansers observed per day at the JD Holmes, Boone, Easton, Stiles, and Lost Creek Pond Coho acclimation sites between 2004 and 2017 when fish were present.

Acclimation site avian abundance varied greatly between manmade concrete structures and natural or manmade ponds. Spring Chinook from the CESRF were acclimated in concrete raceways in three different locations in the Upper Yakima Basin. The raceways were covered with guide wires to control access to fish by piscivorous birds and provide a deterrent to predation. The Belted Kingfisher, due to its small size and fishing style, was the dominant predator in these acclimation sites, but numbers per day remained below any level of concern for management strategies to be implemented (Figure 30).

Coho acclimation was conducted in natural or manmade ponds which were highly accessible to piscivorous birds. The Common Merganser was the most common predator at these Coho acclimation sites (Figure 31). From 2004 to 2017 various ponds were used in alternation as Coho acclimation sites. Boone pond in the upper Yakima Basin showed a tendency to draw large numbers of Common Mergansers during coho acclimation and during recent years has been abandoned as a site of acclimation. Easton pond was used consistently as a Coho acclimation site from 2004 to 2016 (however, no data were available for this pond in 2014). Stiles pond shows relatively little bird use during Coho acclimation. Recent years have shown a steady growth in Common Mergansers utilizing Holmes pond during Coho acclimation; this may be due to the fact of lack of fish at Boone pond.

The most common birds preying on smolts in acclimations sites were the Bald Eagle, Belted Kingfishers, Common Merganser, Great Blue Heron, and Osprey. If it is assumed that birds feeding in acclimation ponds are consuming only smolts on bird days on site, an average of consumption can be calculated using the average number of birds at each site, daily energy requirements of the birds, and the average size of smolts. Calculated estimates assume that acclimation fish were the only prey for the bird species surveyed.

For the Spring Chinook sites (Clark Flat, Easton and Jack Creek), it was estimated that these bird species together consumed 1,002 smolts at Clark Flat, 1,802 smolts at Easton and 329 smolts at Jack Creek. We estimated that Great Blue Heron had the highest consumption rate at Clark Flat, with Bald Eagles consuming the most at Easton, and Common Mergansers consuming the most at Jack Creek.

At the Coho acclimation sites (Holmes and Stiles), Bald Eagles, Belted Kingfishers, Common Mergansers, and Great Blue Herons were the only species observed. At Holmes, it was estimated that 2,395 juvenile Coho were consumed. Common Mergansers were observed on six days, consuming 1,844 juvenile Coho. Great Blue Herons were observed on seven days, consuming 489 juvenile Coho. At Stiles, it was estimated that 2,107 juvenile Coho were consumed. Common Mergansers were observed most days and it's estimated they consumed 2,039 juvenile Coho. In 2016, these bird species together consumed 24,326 juvenile Coho at Easton Pond, 4,342 juvenile Coho at Holmes, 3,460 juvenile Coho at Lost Creek and 5,000 juvenile Coho at Stiles.

## Great Blue Heron Rookeries

Figure 32. Number of PIT tags recovered at Yakima Basin Great Blue Heron rookery sites during surveys conducted from 2008-2017. Tags were from juvenile salmonids migrating downstream between 2000 and 2017. Total PIT tags recovered are shown by their corresponding migration year.

Figure 33. Number of PIT tags recovered at the Selah Great Blue Heron rookery during surveys conducted from 2008-2017. Tags were from juvenile salmonids migrating downstream between 2000 and 2017. Total PIT tags recovered are shown by species and their corresponding migration year.

Figure 34. Number of PIT tags recovered at the Wapato Wildlife Area Great Blue Heron rookery during surveys conducted from 2008-2017. Tags were from juvenile salmonids migrating downstream between 2000 and 2017. Total PIT tags recovered are shown by species and their corresponding migration year.

Surveys of the Yakima Basin Great Blue Heron rookery sites between 2008 and 2017 recovered approximately 18,300 salmonid related PIT tags (Figure 32). Heron rookery PIT recoveries, when sorted by migration year, show higher mortality rates for juvenile migration years 2005 to 2009. This may correspond to river conditions (e.g., lower flows, low turbidity) that are likely conducive to increased smolt mortalities. For example, the migration year of 2008 was the most prevalent in PIT recoveries which could be related to drought conditions in 2007 when many 2008 migrants were released.

PIT recoveries in the Selah Heron Rookery may show the highest correlation to increases in predation opportunities due to low water flows in the Yakima River (Figure 33). Spring Chinook, released in Yakima River waters upriver of the rookery, exhibited the high numbers of PIT recoveries for migration years 2005 and 2007 which were years of relatively low flows in the Yakima River. The Selah Rookery is located near the Roza reach of the Yakima River below Roza Dam which generally produces flows lower than most Yakima River reaches during poor water years. These low flows may inhibit fish passage and increase predation opportunities.

Large numbers of summer Chinook tags have been recovered in some of the most recent years in the Selah Rookery (Figure 33). Beginning in 2013, some summer Chinook were released from a portable acclimation raceway at the Roza juvenile
sampling facility (upstream of Selah; Figure 1). It is also possible that summer Chinook, acclimated at the nearby Stiles pond on the Naches River, could migrate to the Yakima River near the Selah rookery. Anecdotal evidence from the owner of the acclimation pond indicates that Herons congregate at the pond's release channel to the Naches River. These Herons are most likely from the Selah rookery.

The Wapato Wildlife area Great Blue Heron Rookery has produced the highest number of PIT recoveries when compared to all other Yakima Basin Rookeries (Figure 34). While Heron numbers in the rookery are high the overall difference in the Heron numbers when compared with other rookeries in the Basin is minimal. The high numbers of PIT recoveries in this rookery may be due to its location which is near to irrigation diversions and fish screening facilities. Fish diverted into these facilities are subjected to unfavorable flow conditions before being diverted back to the Yakima River via an underground pipe. Fish may become disoriented or severely injured during the diversion process making them susceptible to predation from the nearby Herons. PIT recoveries for summer Chinook migrating downstream in 2009 through 2011 were noticeably high at this rookery (Figure 34). Late release dates, low flows, and release location are the most likely factors related to the high mortality rates of these summer Chinook at the Wapato Rookery.

## Fish Predation Index and Predator Control

Fish predators are also capable of significantly depressing smolt production. Thus the YKFP has a long-established objective to monitor, evaluate, and manage the impact of piscivorous fish on annual smolt production of Yakima Subbasin salmon and steelhead. By indexing the mortality rate of upper Yakima spring Chinook attributable to piscivorous fish in the lower Yakima River, the contribution of in-basin predation to variations in hatchery- and natural-origin spring Chinook smolt-to-adult survival rate can be deduced.

Based on YKFP and WDFW studies of piscivorous fish in the Yakima River Basin (Fritts and Pearsons 2004, 2006, 2008), it was determined that management of the piscivorous fish populations in the area is necessary to improve survival of juvenile salmonids. Initial steps were taken in 2009 to identify locations that would be suitable for a multi-pass removal population study. In early 2010, the YKFP began initial study checks to determine management and study goals for piscivorous fish. Presence and absence of piscivorous fish was determined through electro-fishing various sections of the Yakima River to determine temporal and spatial trends of each species of piscivorous fish. On March 1, 2013, the Washington Fish and Wildlife

Commission adopted numerous changes to sport fishing rules, including the elimination of catch restrictions for non-native predators.

## Methods:

Surveys for piscivorous fish were conducted year round in the Yakima River via electrofishing and were generally consistent with Tiffan et al. (2009) and with monitoringmethods.org methods 47 and $\underline{1712}$. Electro-fishing was conducted by jetboat in the main stem or by backpack in side channels of the Yakima River. A Smith Root vvp-15b electro-fishing unit was used on the main stem while a smith root model 24 backpack unit was used in side channels. The preferred method of electrofishing is pulsed direct current with varying frequencies dependent on specific conductivity and water temperature. The preferred method has been ideal for targeting piscivorous fish while not injuring salmonids. A GPS was used to locate survey transects and to calculate total distance of surveys. Electrode on time was recorded to calculate catch per unit effort, which was used as an estimate of abundance in each survey location. Piscivorous fish were collected during surveys in a bucket and sacrificed at the end of the survey.

During this project year, monthly multi-pass predator removal efforts (generally consistent with monitoringmethods.org methods 438) were conducted from March through August at Selah Gap to Union Gap (Section 1-4), Parker Dam to Toppenish (Sections 5-8), Toppenish to Granger (Sections 9-13), Benton (14-18), and Vangie (19-22) (Figure 35). Transects were approximately 1 mile sections separated by up to 1 mile and were chosen based on river flows (CFS) and ability to continue to survey these areas during low river water flows. Entire transects were sampled for presence of piscivorous fish. A comparative analysis of the multi-pass numbers for each transect was used to determine population numbers of piscivorous fish.

Figure 35. Map of Yakima River Piscivorous Fish Populations Study Areas (highlighted in neon green).

In addition to population estimates, stomach samples were collected from every $5^{\text {th }}$ Northern Pikeminnow (NPM, Ptychocheilus oregonensis) greater than 200 mm in fork length and every $5^{\text {th }}$ Smallmouth bass (Micropterus dolomieu) less than 200 mm in fork length within the transects (monitoringmethods.org method 152 and 4044). NPM stomachs with fish present were further analyzed to determine the number and types of species consumed (monitoringmethods.org methods 1317 and $\underline{1445 \text { ). This analysis }}$ was performed using diagnostic bones which allows determination of species (though for salmonids this is more difficult) and approximate body length.

Survey efforts for 2011 to present also included recording all fish species and their corresponding catch per unit effort for select areas of importance on the Yakima River. Included for the inclusive species monitoring is the Wapato reach, a section of the Yakima River, designated as the area (for the purpose of this report) between Union Gap at USGS River mile 107 to the boundary of the Yakama Indian Reservation at USGS River mile 60. Additional sections of the Yakima River which the species monitoring incorporates are three sections at the Yakima River Delta which include an area of the Yakima River at USGS river mile 1 to the confluence at
the Columbia River, and the Delta sections to the East and West of the Bateman Island Causeway (Figure 36).

The inclusive species monitoring for the Yakima River will be used as an aid for tracking changes in fish populations and abundance as the area experiences global climate change.

Figure 36. Yakima River Delta Survey Areas.

## Results and Discussion:

Wapato Reach fish species included the piscivorous Northern Pikeminnow and 10 other species of fish (Table 27). Relative catch numbers of the Northern Pikeminnow, for 2010 to present, were small compared to other fish species. Fish from the family Catostomidae, or suckers, were the highest relative catch for the Wapato reach (Figure 37). Salmonids were found in high abundance in the Wapato reach; catch abundance was dependent on time of year and is highest during the
salmon smolt out-migration through the reach. The assemblage of fish species in the Wapato Reach were primarily native species. Fish predation in the Wapato Reach was considered to be relatively low compared to the Lower Yakima River where many non-native fish predators were found in abundance.

Table 27. Wapato Reach of the Yakima River - Fish Species identified during surveys 2010-2017.

Northern Pike Minnow were the dominant piscivorous fish in reaches of the Yakima River above Prosser Dam. Catch and CPUE of Northern Pikeminnow can vary widely over time periods in this reach (Figure 38). While numbers vary over seasons it is evident that Northern Pikeminnow populations remain in high numbers over the course of the year.

Figure 37. Wapato Reach of the Yakima River - Relative catch per unit effort by fish family.

Figure 38. Number and Catch per Unit Effort (CPUE) of Northern Pike Minnow observed in surveys of the Yakima River Benton and Wapato Reaches. Data are from 2011-2017 surveys and display NPM presence over varying seasons (Data which exceeds scale is described in text and table 28).

Large amounts of piscivorous fish (many of them introduced species) were found to inhabit the Lower Yakima River, which is defined as that portion of the river between Prosser Dam and the confluence of the Yakima River with the Columbia River. During winter months high amounts of piscivorous fish, in particular NPM, were found in irrigation drains along the Yakima River. These drains remain highly productive over the winter months as their temperatures typically remain higher than the Yakima River and may range up to 10 degrees Celsius higher. Extremely low flows in 2015 prevented catch of NPM in the Yakima River. NPM management did occur in the Yakima River Delta during the fall 2015. In 2017 flows were at higher than average levels in the Yakima River and catch of NPM was highest in the early spring months. High catch rates of NPM in the Wapato Reach of the Yakima River are common in the spring and fall (Table 28). Summer surveys in the Wapato Reach are not typically conducted due to low flows and exposed rocks.

Table 28. Northern Pike Minnow Catch Total and Catch per Unit Effort (Data exceeding scale of Figure 38).

| Date | Location | Total Catch NPM | Adult or Juvenile | CPUE |

Overall from 2011 to 2017, Smallmouth Bass and Channel Catfish were the fish predators observed in the highest abundance in the lower reaches of the Yakima River between Prosser Dam to the confluence Columbia River. It is believed that these two species are a source of significant mortality on out-migrating juvenile salmon.

Smallmouth Bass (SMB) have been found in high numbers in the lower Yakima River and exhibit a spike in abundance during their spawning periods. Spawning for SMB is typically between April 1 and July 1, a time period that coincides with juvenile salmonid outmigration. Thus, the juvenile salmon are a readily available prey item for the adult spawning bass and their young recruits. Catch and catch per unit effort for SMB begins to rise in the May and June survey periods (Figure 39) as SMB migrate
from the Columbia River into the Yakima River to spawn. A rise in catch in adults also correlates with a rise in Yakima River water temperature. As the river exceeds 20 degrees Celsius catch of adult SMB in the Lower Yakima River significantly increases during the early spring. The catch numbers for SMB in the Yakima River saw a significant increase in 2016 but declined in 2017 (Figure 39). This rise and fall of SMB relative abundance may correlate with the water year of 2015 which produced extremely low flows and high water temperatures followed by high water years in 2016 and 2017. It is the increase in water temperature in the lower Yakima River which is thought to create productive habitat for SMB. Across all years there is increased catch success during the late summer and fall months and electro-fishing efforts are increased to maximize catch for managing numbers of SMB in the lower Yakima River. As part of our efforts to increase salmon populations, we are targeting SMB populations for management in hopes to increase survival of juvenile salmon outmigrants.

Figure 39. Number and Catch per Unit Effort (CPUE) of Smallmouth Bass observed in surveys of the Lower Yakima River (Data which exceeds scale is described in text and Table 29).

Table 29. Smallmouth Bass Catch Total and Catch per Unit Effort (Data exceeding scale of Figure 39).

| Date | Location | Total Catch SMB | Adult or Juvenile | CPUE |
| :---: | :---: | :---: | :---: | :---: |
| $5 / 2 / 2016$ | Lower Yakima Reach | 74 | Adult | 0.45 |

|  |  | 224 | Juvenile | 3.56 |

Yakima River Delta surveys from 2010 to 2017 found 23 different fish species occupied the delta at varying temporal and spatial distributions (Table 30). This is twice the number of fish species in the Delta when compared to the fish species of the Wapato Reach. Many of the fish species in the delta are introduced, non-native fish and are a warm-water species of fish. These introduced fish are adapted to the highly altered water conditions, of increased temperatures and low dissolved oxygen, which the Yakima delta displays. Water temperatures may reach highs of 80 degrees Fahrenheit in the late summer months. Relative catch abundance in the Yakima Delta for the surveys shows a high number of fish from the families of: Centrarchidae, Cyprinidae, and Ictaluridae (Figure 40). These families are highly represented because of large numbers of piscivorous fish present in the delta. Smallmouth Bass, Largemouth Bass, and numerous catfish are present here and use the area for spawning and rearing of juveniles.

When comparing the Wapato Reach Species/Relative Catch Abundance (Figure 37) to the Yakima Delta Species/Relative Catch Abundance (Figure 40) a glaring contrast in the type of fish and their abundance between the two sections of the Yakima River is obvious. In the upper portion of the Yakima River, where natural attributes such as water temperature, riparian cover, nutrient loading, and flow that is closer to historical values the fish species consist of native species which are adapted to cold water conditions. In the lower section of the Yakima River and the Yakima River delta river attributes have been highly altered by: dams, irrigation diversions, water drawn for power, lowered flows, little riparian cover, irrigation water returned loaded with nutrients, and a blocked section of the river delta, fish species consist of a high number of introduced species many of which are piscivorous.

Table 30. Yakima River Delta - Fish Species identified during surveys 2010-2017.

Figure 40. Yakima River Delta - Relative catch per unit effort by fish family.

SMB in the delta of the Yakima River have been found in surprisingly high numbers. The Yakima delta at all times of year contains some presence of SMB and during fall abundance of juvenile SMB reaches peak numbers. Late summer and fall temperatures in the Yakima Delta can exceed 27 degrees Celsius coupled with the blockage of the flow by the causeway this area Yakima River becomes similar to a warm water lake. While catch of SMB in the Delta remains lower than 100 fish per day at most times of year (Figure 41) the rise in the fall numbers can be astounding. The increase in SMB numbers during this time is primarily due to presence of juvenile SMB and catch total has risen to above 3000 fish in a day (Figure 41, data which exceeds scale) with catch totals of 500 fish per day very common.

Figure 41. Number and Catch per Unit Effort (CPUE) of Smallmouth Bass observed in surveys of the Yakima River Delta area (West of the Bateman Island Causeway; data which exceeds scale is described in text).

## Adaptive Management and Lessons Learned

As noted extensively throughout this report, this project is a collaborative effort involving many agencies, boards, and individuals. As such, project coordination and review of project standards and protocols occurs continually amongst tribal, state, federal, and local entities during normal day-to-day operations of the project. Project results are communicated broadly through the annual science and management conference, technical reports and peer-reviewed journal publications (see references and project-related publications), and via several related web sites described in Appendix A.

We support the principles established in Mobrand et al. (2005) and Paquet et al. (2011) that hatchery programs should be well-defined, scientifically defensible, and use informed decision making tools including adaptive management. Many of these principles were initially published in Cuenco et al. (1993) including specific recommended decision criteria, management protocols, release strategies, and risk management strategies for hatchery programs. We designed a number of these protocols and strategies into the CESRF program and they are clearly contributing to
the results documented here for the Upper Yakima River Basin spring Chinook populations.

Results to date from Yakama Nation supplementation and research efforts in the Yakima River Basin indicate several lessons that may be of broader application on the regional scale.

1. We need to be realistic. Can or should we expect to see "self-sustaining natural populations" in river systems that have been highly altered from their historical state due to ever-increasing human demands on shared resources? In the highly altered systems we live and work in today, hatchery programs provide a necessary means to ameliorate some of the effects of human population growth and development.
2. We need to be honest. Hatchery programs are not the cause of poor productivity. The historical record is replete with documentation (see Dompier 2005) that the region knew exactly what it was doing to natural salmon productivity when development of the region began to intensify with implementation of the Federal Columbia River Power System as early as the 1930s.
3. We need to be patient. Hatchery reform is a relatively new concept and results for longer term 20-25 year efforts such as the Idaho Supplementation Studies (ISS; Venditti et al. 2017) and CESRF program (Fast et al. 2015) are only now becoming available. These programs empirically support the idea that hatchery reform principles can provide the expected benefits.
4. While hatchery supplementation has demonstrated increases in natural production (increased redd and juvenile abundance), supplementation by itself cannot and was never intended to increase natural productivity. To accommodate expanding human population growth and resource demand, it is imperative that we continue and even increase habitat restoration actions to ensure that sufficient spawning and rearing habitat remains available to all naturally spawning fish.
5. Every subbasin, species, and study is unique, so we should not be surprised to see differing results from the many studies of hatchery effects that are ongoing. Researchers need to continue efforts to better understand the root causes of poor natural productivity and the extent to which hatchery programs effect productivity.
6. Evaluation of hatchery programs should include evaluation of environmental and other factors so that hatchery effects are properly reported.
7. Hatchery programs should be regularly evaluated at the local level using expertise across disciplines to collaboratively and iteratively develop appropriate solutions that address the unique problems and limiting factors encountered in each subbasin or tributary that hosts a hatchery program. In the Yakima Basin, this is achieved with the annual Yakima Basin Aquatic Science and Management Conference, and we use the results to evaluate existing goals, objectives, and strategies and to adaptively manage projects in response to new information.

## Appendix A: Use of Data \& Products

All data and findings should be considered preliminary until results are published in the peer-reviewed literature.

## Where will you post or publish the data your project generates?

## Fish Passage Center

Yakama Nation Fisheries website
DART - Data Access in Real Time
RMIS - Regional Mark Information System
Yakima-Klickitat Fisheries Project website
StreamNet Database
cbfish.org
PTAGIS Website
Washington State SaSI
A system has been developed that serves Yakima Basin adult abundance and trap sampling (requires login) data for the Prosser and Roza data sets. This system can be accessed at: http://dashboard.yakamafish-star.net/FishData.

Describe the accessibility of the data and what the requirements are to access them?

- Prosser and Roza dam daily count and trap sample (requires login) data http://dashboard.yakamafish-star.net/FishData.
- Integration of PIT and CWT release and recovery data with PTAGIS, RMIS, and Fish Passage Center databases
- Production and support of data bases necessary to support BPA quarterly and annual reports (e.g., PISCES, available via CBfish.org)
- Production and support of data bases necessary to support NPCC project proposals (available via CBfish.org)
Additional data is available on the ykfp.org web site and by email contact through the data managers (Yakima Basin, contact Bill Bosch, bbosch@yakama.com; Klickitat Basin, contact Michael Babcock, mbabcock@ykfp.org). Project data managers continue to participate in the Coordinated Assessments process to develop pilot exchange templates for adult and juvenile abundance and productivity parameters. However, we continue to believe that the best way to prioritize our data management work load is to develop databases to store the status and trend data we have been collecting over many years as well as the web tools necessary to access these data in downloadable format. The system we have developed to share Prosser and Roza dam daily count and trap sample data is an example of the progress we are making towards this end.

## Acknowledgments

Monitoring and evaluation efforts for the Cle Elum Supplementation and Research Facility (CESRF) and Yakima River spring Chinook salmon are the result of a cooperative effort by many individuals from a variety of agencies including the Yakama Nation Fisheries Program (YN), the Washington Department of Fish and Wildlife (WDFW), the United States Fish and Wildlife Service (USFWS), the National Oceanic and Atmospheric Administration Fisheries department (NOAA Fisheries) as well as some consultants and contractors.

The core project team includes the following individuals: Dave Fast, Mark Johnston, Bill Bosch, David Lind, Paul Huffman, Joe Hoptowit, and a number of technicians from the YN; Charles Strom and a number of assistants from the CESRF; Anthony Fritts, Gabe Temple, Christopher Johnson, and a number of assistants from the WDFW; Curt Knudsen from Oncorh Consulting and Doug Neeley from IntSTATS Consulting; Sharon Lutz and assistants from the USFWS; and Don Larsen, Andy Dittman, and assistants from NOAA Fisheries. The technicians and assistants are too numerous and varied to mention each by name (and risk leaving some out). However, their hard work in the field is the source of much of the raw data needed to complete this report. We sincerely appreciate their hard work and dedication to this project.

We would especially like to thank former members of the Yakima/Klickitat Fisheries Project, Bruce Watson, Joel Hubble, Bill Hopley, Todd Pearsons, Steve Schroder, and Craig Busack. These individuals put in countless hours of hard work during the planning, design, and implementation of this project. Their contributions helped to lay a solid foundation for this project and our monitoring and evaluation efforts. Dan Barrett (retired) served as the manager of the CESRF from 1997-2002. He helped to lay a solid foundation for the critical work done day in and day out at the Cle Elum facility.

We also need to recognize and thank the Yakama Nation and WDFW for their continued support, and the Columbia River Inter-Tribal Fish Commission, the University of Idaho, the Pacific States Marine Fisheries Commission, Mobrand, Jones, and Stokes, and Central Washington University for their many contributions to this project including both recommendations and data services.

This work is funded by the Bonneville Power Administration (BPA) through the Northwest Power and Conservation Council’s (NPCC) Fish and Wildlife Program. Michelle O'Malley is BPA's contracting officer and technical representative (COTR) for this project. David Byrnes and Patricia Smith preceded Michelle in this position and contributed substantially to the project over the years.

#### Abstract

Historically, the return of spring Chinook salmon (Oncorhynchus tshawytscha) to the Yakima River numbered about 200,000 fish annually (BPA, 1990). Spring Chinook returns to the Yakima River averaged fewer than 3,500 fish per year through most of the 1980s and 1990s (less than 2\% of the historical run size).

In an attempt to reverse this trend the Northwest Power and Conservation Council (formerly the Northwest Power Planning Council, NPPC) in 1982 first encouraged Bonneville Power Administration (BPA) to "fund the design, construction, operation, and maintenance of a hatchery to enhance the fishery for the Yakima Indian Nation as well as all other harvesters" (NPPC 1982). After years of planning and design, an Environmental Impact Statement (EIS) was completed in 1996 and the CESRF was authorized under the NPCC's Fish and Wildlife Program with the stated purpose being "to test the assumption that new artificial production can be used to increase harvest and natural production while maintaining the long-term genetic fitness of the fish population being supplemented and keeping adverse genetic and ecological interactions with non-target species or stocks within acceptable limits". The CESRF became operational in 1997. This project is co-managed by the Yakama Nation and the Washington Department of Fish and Wildlife (WDFW) with the Yakama Nation as the lead entity.

This report documents data collected from Yakama Nation tasks related to monitoring and evaluation of the CESRF and its effect on natural populations of spring Chinook in the Yakima Basin through 2017. This report is not intended to be a scientific evaluation of spring Chinook supplementation efforts in the Yakima Basin. Rather, it is a summary of methods and data (additional information about methods used to collect these data may be found in the main section of this annual report) relating to Yakima River spring Chinook collected by Yakama Nation biologists and technicians from 1982 (when the Yakama Nation fisheries program was implemented) to present. Data summarized in this report include: - Adult-to-adult returns - Annual run size and escapement - Adult traits (e.g., age composition, size-at-age, sex ratios, migration timing, etc.) - CESRF reproductive statistics (including fecundity and fish health profiles) - CESRF juvenile survival (egg-to-fry, fry-to-smolt, smolt-to-smolt, and smolt-toadult) - CESRF juvenile traits (e.g., length-weight relationships, migration timing, etc.) - Harvest impacts

The data presented here are, for the most part, "raw" data and should not be used without paying attention to caveats associated with these data and/or consultation with project biologists. No attempt is made to explain the significance of these data in this report as this is left to more comprehensive reports and publications produced by the project. Data in this report should be considered preliminary until published in the peer reviewed literature.

## Introduction

## Program Objectives

The CESRF was authorized in 1996 under the NPCC’s Fish and Wildlife Program with the stated purpose being "to test the assumption that new artificial production can be used to increase harvest and natural production while maintaining the long-term genetic fitness of the fish population being supplemented and keeping adverse genetic and ecological interactions with non-target species or stocks within acceptable limits". The CESRF became operational in 1997. The experimental design calls for a total release of 810,000 smolts annually from each of three acclimation sites associated with the facility (see facility descriptions). To minimize risk of over-collecting brood stock and to maintain lower pond rearing densities, the YKFP policy group took action in 2011 to reduce the release target to 720,000 smolts for brood collection purposes. Female percentage, fecundity and survival rates are expected to result in releases between 720,000 and 810,000 smolts in most years. The first program cycle (brood years 1997 through 2001) also included testing new Semi-Natural rearing Treatments (SNT) against the Optimum Conventional Treatments (OCT) of existing successful hatcheries in the Pacific Northwest. The second program cycle (brood years 2002-2004) tested whether a slower, more natural growth regime could be used to reduce the incidence of precocialism that may occur in hatchery releases without adversely impacting overall survival to adult returns. Brood years 2005-2007 tested survival using different types of feed treatment. Subsequent broods have used a standard treatment in all raceways. With guidance and input from the NPCC and the Independent Scientific Review Panel (ISRP) in 2001, the Naches subbasin population of spring Chinook was established as a wild/natural control. A hatchery control line at the CESRF was also established with the first brood production for this line collected in 2002. Please refer to the project's "Supplementation Monitoring Plan" (Chapter 7 in 2005 annual report on project genetic studies) for additional information regarding these control lines.

## Facility Descriptions

Returning adult spring Chinook are monitored at the Roza adult trapping facility located on the Yakima River (Rkm 205.8). This facility provides the means to monitor every fish returning to the upper Yakima Basin and to collect adults for the CESRF program. All returning CESRF fish (adipose-clipped fish) are sampled for biological characteristics and marks and returned to the river with the exception of fish collected for broodstock, experimental sampling, and all hatchery control line fish. Through 2006, all wild/natural fish passing through the Roza trap were returned directly to the river with the exception of fish collected for broodstock or fish with metal tag detections which were sampled for marks and biological characteristics. Beginning in 2007, all wild/natural fish were sampled (as described above) and tissue samples were collected for a "Whole Population" Pedigree Study of Upper Yakima Spring Chinook (see related project 2009-009-00).

The CESRF is located on the Yakima River just south of the town of Cle Elum (rkm 295.5). It is used for adult broodstock holding and spawning, and early life incubation and rearing. Fish are spawned in September and October of a given brood year (BY). Fish are typically ponded in March or April of BY+1. The juveniles are reared at Cle Elum, marked in October through

December of BY+1, and moved to one of three acclimation sites for final rearing in January to February of BY+2. Acclimation sites are located at Easton (ESJ, rkm 317.8), Clark Flats near the town of Thorp (CFJ, rkm 266.6), and Jack Creek (JCJ, approximately 32.5 km north of Cle Elum) on the North Fork Teanaway River (rkm 10.2). Fish are volitionally released from the acclimation sites beginning on March 15 of BY+2, with any remaining fish "flushed out" of the acclimation sites by May 15 of $\mathrm{BY}+2$. The annual production goal for the CESRF program is 720,000 to 810,000 fish for release as yearlings at $30 \mathrm{~g} /$ fish or 15 fish per pound (fpp) although size-at-release may vary depending on experimental protocols (see Program Objectives).

## Yakima River Basin Overview

The Yakima River Basin is located in south central Washington. From its headwaters near the crest of the Cascade Range, the Yakima River flows 344 km ( 214 miles) southeastward to its confluence with the Columbia River (Rkm 539.5; Figure 1).

Figure 1. Yakima River Basin.

Three genetically distinguishable populations of spring Chinook salmon exist in the Yakima basin: the American River, the Naches, and the Upper Yakima Stocks (Figure 1). The upper Yakima was selected as the population best suited for supplementation and associated evaluation and research efforts.

Local habitat problems related to irrigation, logging, road building, recreation, agriculture, and livestock grazing have limited the production potential of spring Chinook in the Yakima River basin. It is hoped that recent initiatives to improve habitat within the Yakima Basin, such as those being funded through the NPCC's fish and wildlife program, the Pacific Coastal Salmon Recovery Fund, and the Washington State salmon recovery fund, will: 1) restore and maintain natural stream stability; 2) reduce water temperatures; 3) reduce upland erosion and sediment delivery rates; 4) improve and re-establish riparian vegetation; and 5) re-connect critical habitats throughout the basin. These habitat restoration efforts should permit increased utilization of habitat by spring Chinook salmon in the Yakima basin thereby increasing fish survival and productivity.

## Adult Salmon Evaluation

## Broodstock Collection and Representation

One of the program's goals is to collect broodstock from a representative portion of the population throughout the run. If the total run size could be known in advance, collecting brood stock on a daily basis in exact proportion to total brood need as a proportion of total run size would result in ideal run representation. Since it is not possible to know the run size in advance, the CESRF program uses a brood collection schedule that is based on average run timing once the first fish arrive at Roza Dam. We have found that, while river conditions dictate run timing (i.e., fish may arriver earlier or later depending on flow and temperature), once fish begin to move at Roza, the pattern in terms of relative run strength over time is very similar from year to year. Thus a brood collection schedule matching normal run timing patterns was developed to assure that fish are collected from all portions of the run (Figure 2).

Figure 2. Mean spring Chinook run timing and broodstock collection at Roza Dam, 2008-2017.
Another program goal is to take no more than $50 \%$ of the wild/natural adult return to Roza Dam for broodstock. Given this goal and with a set brood collection schedule at Roza Dam, the project imposed a rule that no more than $50 \%$ of the fish arriving on any given day be taken for broodstock. Under-collection relative to the schedule is "carried over" to subsequent days and weeks. This allows brood collection to adjust relative to actual run timing and run strength. Performance across years with respect to these brood collection goals is given in Table 1. In 2015 the spring Chinook return was impaired by a thermal barrier in the lower Yakima River due to lack of winter snowpack and hot spring and summer air temperatures. This combined to severely reduce summer and fall flows and increase water temperatures. Mean daily water temperatures at Kiona (rkm 40 from the mouth of the Yakima R.) exceeded $70^{\circ} \mathrm{F}$ every day from May 21 to August 29, 2015 (source U.S. BOR hydromet database). Thus, a large number of fish were delayed and passed Roza Dam in the later part of the 2015 migration period.

Table 1. Counts of wild/natural spring Chinook (including jacks), brood collection, and brood representation of wild/natural run at Roza Dam, 1997 - present.

| Year | Trap Count | Brood Take | Brood \% | Portion of run collected: ${ }^{1}$ |  |  | Portion of collection from: ${ }^{2}$ |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  | Early ${ }^{3}$ | Middle ${ }^{3}$ | Late ${ }^{3}$ | Early ${ }^{3}$ | Middle ${ }^{3}$ | Late ${ }^{3}$ |

| 2003 | 1,558 | 441 | 28.3\% | 52.5\% | 25.9\% | 36.4\% | 9.5\% | 77.8\% | 12.7\% |
| 2004 | 7,804 | 597 | 7.6\% | 2.6\% | 7.4\% | 12.8\% | 2.0\% | 81.6\% | 16.4\% |
| 2005 | 5,086 | 510 | 10.0\% | 2.2\% | 9.5\% | 21.9\% | 1.3\% | 77.0\% | 21.7\% |
| 2006 | 2,050 | 419 | 20.4\% | 48.5\% | 22.2\% | 41.0\% | 9.1\% | 75.1\% | 15.8\% |
| 2007 | 1,293 | 449 | 34.7\% | 25.0\% | 34.4\% | 60.6\% | 3.2\% | 80.0\% | 16.9\% |
| 2008 | 1,677 | 457 | 27.3\% | 57.7\% | 26.7\% | 32.4\% | 9.3\% | 79.0\% | 11.6\% |
| 2009 | 3,030 | 486 | 16.0\% | 10.0\% | 14.1\% | 35.9\% | 3.5\% | 73.9\% | 22.6\% |
| 2010 | 3,185 | 336 | 10.5\% | 6.4\% | 15.0\% | 22.5\% | 2.0\% | 82.6\% | 15.3\% |
| 2011 | 4,395 | 377 | 8.6\% | 11.3\% | 9.2\% | 21.3\% | 5.6\% | 73.2\% | 21.2\% |
| 2012 | 2,924 | 374 | 12.8\% | 1.9\% | 12.3\% | 27.4\% | 1.1\% | 79.9\% | 19.0\% |
| 2013 | 2,784 | 398 | 14.3\% | 18.5\% | 13.0\% | 22.0\% | 9.5\% | 75.1\% | 15.3\% |
| 2014 | 4,168 | 384 | 9.2\% | 4.8\% | 8.6\% | 16.9\% | 2.3\% | 80.5\% | 17.1\% |
| 2015 | 3,962 | 442 | 11.2\% | 3.1\% | 8.2\% | 40.6\% | 2.0\% | 59.9\% | 38.1\% |
| 2016 | 2,712 | 376 | 13.9\% | 5.3\% | 14.8\% | 18.6\% | 2.5\% | 84.7\% | 12.9\% |
| 2017 | 1,711 | 382 | 22.3\% | 53.6\% | 19.0\% | 45.4\% | 11.4\% | 69.9\% | 18.7\% |

1. This is the proportion of the earliest, middle, and latest running components of the entire wild/natural run which were taken for broodstock. Ideally, this collection percentage would be equal throughout the run and would match the "Brood \%".
2. This is the proportion of the total broodstock collection taken from the earliest, middle, and latest components of the entire wild/natural run. Ideally, these proportions would match the definitions for early, middle, and late given in 3.
3. Early is defined as the first $5 \%$ of the run, middle is defined as the middle $85 \%$, and late as the final $10 \%$ of the run.

## Natural- and Hatchery-Origin Escapement

While the project does not actively manage for a specific spawning escapement proportion (natural- to hatchery-origin adults), we are monitoring the proportion of natural influence (PNI; Table 2). The project will adaptively manage this parameter considering factors such as: policy input regarding surplusing of fish, meeting overall production goals of the project, guidance from the literature relative to percentage of hatchery fish on the spawning grounds with fitness loss, considerations about what risk is acceptable in a project designed to evaluate impacts from that risk, and the numerous risk containment measures already in place in the project. The State of Washington is using mark-selective fisheries in the lower Columbia River and, when possible, in the lower Yakima River in part as a tool to manage escapement proportions. In 2011, the project initiated an effort to transfer some returning hatchery-origin CESRF adults from Roza Dam to Lake Cle Elum for the purpose of returning marine derived nutrients and salmon to the watersheds that feed the lake. This effort will also increase PNI in the major spawning areas of the Upper Yakima Basin. Natural- and hatchery-origin escapement to the upper Yakima Basin is given in Table 2. Wild/natural escapement to the Naches subbasin is given in Table 3.

Table 2. Escapement (Roza Dam counts less brood stock collection and harvest above Roza) of natural(NoR) and hatchery-origin (HoR) spring Chinook to the upper Yakima subbasin, 1982 - present.

|  | Wild/Natural (NoR) |  |  | CESRF (HoR) |  |  |  | Total Jacks | Total | $\mathrm{pHOS}^{1}$ | PNI ${ }^{1}$ |

1. Proportion Natural Influence equals Proportion Natural-Origin Broodstock (pNOB; 1.0 as only NoR fish are used for supplementation line brood stock) divided by pNOB plus Proportion Hatchery-Origin Spawners (pHOS).
2. This is a rough estimate since Roza counts are not available for 1991.
3. For NoR columns, mean of 1997-present values. For all other columns, mean of 2001-present values.

## Adult-to-adult Returns

The overall status of Yakima Basin spring Chinook is summarized in Table 3. Adult-to-adult return and productivity data for the various populations are given in Tables 4-8 (Means are for 1988 to present).

Table 3. Yakima River spring Chinook run (CESRF and wild, adults and jacks combined) reconstruction, 1988-present.

| Year | River Mouth Run Size ${ }^{1}$ |  |  | Harvest Below Prosser | Prosser <br> Count | Harvest Above Prosser | Spawners <br> Below <br> Roza ${ }^{2}$ | Roza <br> Count | Roza Removals ${ }^{3}$ | Est. Escapement |  | Redd Counts |  |

1. River Mouth run size is the greater of the Prosser count plus lower river harvest or estimated escapement plus all known harvest and removals.
2. Estimated as the average number of fish per redd in the upper Yakima times the number of redds between the Naches confluence and Roza Dam.
3. Roza removals include harvest above Roza, hatchery removals, and/or wild broodstock removals.
4. Estimated escapement into the upper Yakima River is the Roza count, less harvest or broodstock removals above Roza Dam except in 1991 when Upper Yakima River escapement is estimated as the (Prosser count - harvest above Prosser - Roza subtractions) times the proportion of redds counted in the upper Yakima.
5. Naches River escapement was estimated as the Prosser count, less harvest above Prosser and the Roza counts, except in 1982 , 1983 and 1990 when it was estimated as the upper Yakima fish/redd times the Naches redd count.
6. Recent 10-year average (2008-2017).

Appendix B. Yakima River / CESRF Spring Chinook Salmon - Yakama Nation Data Summary
2017 Annual Report, May 31, 2018

Estimated spawners for the Upper Yakima River are calculated as the estimated escapement to the Upper Yakima plus the estimated number of spawners in the Upper Yakima between the confluence with the Naches River and Roza Dam (Table 3). Total returns are based on the information compiled in Table 3. Age composition for Upper Yakima returns is estimated from spawning ground carcass scale samples for the years 1982-1996 (Table 11) and from Roza Dam brood stock collection samples for the years 1997 to present (Table 13). Since age-3 fish (jacks) are not collected for brood stock in proportion to the jack run size, the proportion of age-3 fish in the upper Yakima for 1997 to present is estimated using the proportion of jacks (based on visual observation) counted at Roza Dam relative to the total run size.

Table 4. Adult-to-adult productivity indices for upper Yakima wild/natural stock.

| Brood <br> Year | Estimated <br> Spawners | Age-3 |  | Age-4 | Age-5 | Total |
| :---: | ---: | ---: | ---: | ---: | ---: | ---: | | Returns/ |
| :---: |
| Spawner |

1. The mean jack proportion of spawning escapement from $1999-2017$ was 0.22 (geometric mean 0.17 ).

Estimated spawners for the Naches/American aggregate population (Table 7) are calculated as the estimated escapement to the Naches Basin (Table 3). Estimated spawners for the individual Naches and American populations are calculated using the proportion of redds counted in the Naches Basin (excluding the American River) and the American River, respectively (see Table 31). Total returns are based on the information compiled in Table 3. Age composition for Naches Basin age-4 and age-5 returns are estimated from spawning ground carcass scale samples (see Tables 9-12). The proportion of age-3 fish is estimated after reviewing jack count (based on visual observations) data at Prosser and Roza dams. Since sample sizes for carcass surveys in the American and Naches Rivers can be very low in some years (Tables 9 and 10), it is recommended that the data in Tables 5 and 6 be used as indices only. Table 7 likely provides the most accurate view of overall productivity rates in the Naches River Subbasin.

Table 5. Adult-to-adult productivity indices for Naches River wild/natural stock.

| Mean | 1,780 | 164 | 1,120 | 731 | 7 | 2,021 | 1.64 |

1. The mean jack proportion of spawning escapement from 1999-2017 was 0.09.
2. Age composition using only Naches survey samples in 2010 return year.

Estimated spawners at the CESRF are the total number of wild/natural fish collected at Roza Dam and taken to the CESRF for production brood stock. Total returns are based on the information compiled in Table 3 and at Roza dam sampling operations. Age composition for CESRF fish is estimated using scales and PIT tag detections from CESRF fish sampled passing upstream through the Roza Dam adult monitoring facility.
Table 8. Adult-to-adult productivity for Cle Elum SRF spring Chinook.

1. 357 or $48 \%$ of these fish were jacks.
2. Geometric mean.

## Age Composition

Comparisons of the age composition in the Roza adult monitoring facility (RAMF) samples and spawning ground carcass recovery samples show that older, larger fish are recovered as carcasses on the spawning grounds at significantly higher rates than younger, smaller fish (Knudsen et al. 2003 and Knudsen et al. 2004). Based on historical scale-sampled carcass recoveries between 1986 and 2016 (there were no carcass recoveries in 2017 due to fires in survey areas), age composition of American River spring Chinook has averaged $1,44,54$, and 1 percent age- $3,-4,-5$, and -6 , respectively (Table 9). Naches system spring Chinook averaged 2, 61, 36 and 0.5 percent age-3, $-4,-$ 5 and -6, respectively (Table 10). The upper Yakima River natural origin fish averaged 8,88 , and 4 percent age- $3,-4$, and -5 , respectively (Table 11). While these ages are biased toward the older age classes, we believe the bias is approximately equal across populations and is a good relative indicator of differences in age composition between populations. The data show distinct differences with the American River population having the oldest age of maturation, followed closely by the Naches system and then the upper Yakima River which has significantly more age-3's, fewer age-5’s and no age-6 fish.

Table 9. Percentage by sex and age of American River wild/natural spring Chinook carcasses sampled on the spawning grounds and sample size ( n ), 1986-present.

| Return Year | Males |  |  |  |  | Females |  |  |  |  | Total |  |  |  |

Carcasses from upper Yakima River CESRF origin fish allowed to spawn naturally have also been sampled since age-4 adults began returning in 2001. These fish averaged 13, 85 , and 1 percent age-3, -4 , and -5 , respectively (Table 12) from 2001-2014 compared to 8,88 , and 4.3 percent respectively for their wild/natural counterparts in the upper Yakima for the same years (Table 11). The observed difference in age distribution between wild/natural and CESRF sampled on the spawning grounds may be due in part to the carcass recovery bias described above. A better comparison of age distribution between upper Yakima wild/natural and CESRF fish is from samples collected at Roza Dam which are displayed in Tables 13 and 14. However, it must be noted that jacks (age-3 males) were collected at Roza in proportion to run size from 1997 to 1999, but from 2000-present we have attempted to collect them at their mean brood representation rate (approximately 7\% of the spawning population). Age-3 females do occur rarely in the Upper Yakima population, but it is likely that the data in Table 13 slightly over-represent the proportion of age-3 females due to human error associated with scale collection, handling, processing, and management and entry of these data.

Table 12. Percentage by sex and age of upper Yakima River CESRF spring Chinook carcasses sampled on the spawning grounds and sample size ( n ), 2001-present.

Appendix B. Yakima River / CESRF Spring Chinook Salmon - Yakama Nation Data Summary 2017 Annual Report, May 31, 2018

## Sex Composition

In the American River, the mean proportion of males to females in wild/natural carcasses sampled on the spawning grounds from 1986-2016 was 41:59 for age-4 and 33:67 for age- 5 spring Chinook (Table 15). In the Naches River, the mean proportion of males to females was 41:59 for age-4 and 27:73 for age-5 fish (Table 16). In the upper Yakima River, the mean proportion of males to females was 33:67 for age-4 and 23:77 for age-5 fish (Table 17). Fires precluded collection of carcass samples from the spawning grounds throughout the Yakima Basin in 2017.

For upper Yakima fish collected at Roza Dam for brood stock or research purposes from 1997-2017, the mean proportion of males to females was 38:62 and 35:65 for age-4 fish from the wild/natural and CESRF populations, respectively (Tables 19 and 20). For these same samples, the mean proportion of males to females was 38:62 and 41:59 for age-5 fish from the wild/natural and CESRF populations (excluding years with very small age-5 sample sizes), respectively (Tables 19 and 20). For adult fish, the mean proportion of males to females in spawning ground carcass recoveries was substantially lower than the ratio found at RAMF (Tables 17 and 19), indicating that sex ratios estimated from hatchery origin carcass recoveries were biased due to female carcasses being recovered at higher rates than male carcasses (Knudsen et al, 2003 and 2004). Again, despite these biases, we believe these data are good relative indicators of differences in sex composition between populations and between years.

Sample sizes for Tables 15-20 were given in Tables 9-14. As noted earlier, few age-6 fish are found in carcass surveys and those that have been found were located in the American and Naches systems. The data indicate that age-3 females may occasionally occur in the upper Yakima and, to a lesser extent, the Naches systems.

## Size at Age

Prior to 1996, samplers were instructed to collect mid-eye to hypural plate (MEHP) lengths from carcasses surveyed on the spawning grounds. From 1996 to present the method was changed and post-eye to hypural plate (POHP) lengths have been recorded. Mean POHP lengths averaged 39, 61, and 76 cm for age- 3 , -4 , and -5 males, and averaged 63 and 72 cm for age- 4 and -5 females, respectively, from carcasses sampled on the spawning grounds in the American River from 1996-2016 (Table 21). In the Naches River, mean POHP lengths averaged 42, 60, and 76 cm for age-3, -4 , and -5 males, and averaged 61 and 72 cm for age-4 and -5 females, respectively (Table 22). For wild/natural spring Chinook sampled on the spawning grounds in the upper Yakima River, mean POHP lengths averaged 44, 60, and 72 cm for age-3, -4 , and -5 males, and averaged 59 and 69 cm for age- 4 and -5 females, respectively (Table 23). Beginning in 2012, carcass sampling in the Upper Yakima was scaled back considerably as large numbers of escaping fish are sampled at Roza Dam (Tables 27-28). From 2001-2017, CESRF fish returning to the upper Yakima have been generally smaller in size-at-age than their wild/natural counterparts (Tables 23-28).

Table 21. Counts and mean mid-eye (MEHP) or post-orbital (POHP) to hypural plate lengths (cm) of American River wild/natural spring Chinook from carcasses sampled on the spawning grounds by sex and age, 1986-present.

## Migration Timing

Wild/natural spring Chinook adults returning to the upper Yakima River have generally shown earlier passage timing at Roza Dam than CESRF spring Chinook (Figures 2 and 3).

Figure 3. Proportionate passage timing at Roza Dam of wild/natural and CESRF adult spring Chinook (including jacks), 2008-2017.

Table 29. Comparison of $5 \%$, median ( $50 \%$ ), and $95 \%$ passage dates of wild/natural and CESRF adult spring Chinook (including jacks) at Roza Dam, 1997-Present.

1. In 2000 all returning CESRF fish were age-3 (jacks).
2. Mean daily water temperatures at Kiona (rkm 40 from the mouth of the Yakima R.) exceeded $70^{\circ} \mathrm{F}$ every day from May 21 to August 29, 2015 (source U.S. BOR hydromet database) causing delayed passage for late migrating fish.

## Spawning Timing

Median spawn timing for CESRF spring Chinook is earlier than that observed for wild/natural fish in the Upper Yakima River. These differences are due in part to environmental conditions and spawning procedures at the hatchery. It must also be noted that spawning dates in the wild are only a coarse approximation, derived from weekly redd counts not actual dates of redd deposition. A clear delineation of wild/natural spawn timing between subbasins is apparent, with American River fish spawning about 1 month earlier than Naches Basin fish which spawn about 2 weeks earlier than Upper Yakima fish.
Table 30. Median spawn ${ }^{1}$ dates for spring Chinook in the Yakima Basin.

## Homing

A team from NOAA fisheries conducted studies to determine the spatial and temporal patterns of homing and spawning by wild and hatchery-reared salmon released from CESRF facilities from 2001 to 2010. These studies collected GPS information on each redd and carcass recovered within a survey reach. Carcass surveys were conducted annually in late-September to early October by NOAA personnel in cooperation with Yakama Nation survey crews over five different reaches of the upper Yakima River and recorded the location of each redd flagged and carcass recovered. For each carcass sex, hatchery/wild, male status (full adult, jack, mini-jack), and CWT location was recorded. Data collected on the body location of CWTs allowed the identification of the release site of some fish. While these studies were not designed to comprehensively map carcasses and redds in all spawning reaches in the upper watershed, preliminary data indicate that fish from the Easton, Jack Creek, and Clark Flat acclimation facilities had distinct spawner distributions. A more complete description of this project is available from NOAA fisheries and in this publication:

Dittman, A. H., D. May, D. A. Larsen, M. L. Moser, M. Johnston, and D. Fast. 2010. Homing and spawning site selection by supplemented hatchery- and naturalorigin Yakima River spring Chinook salmon. Transactions of the American Fisheries Society 139:1014-1028.

## Straying

The regional PTAGIS (PIT tag) and RMIS (CWT) databases were queried in late November 2017 to determine the number of CESRF releases not returning to the Yakima River Basin. For adult (age-3, -4, or -5) PIT tagged fish, a stray is defined as detection at an out-of-basin facility in the Snake (Ice Harbor or Lower Granite) or Upper Columbia (Priest Rapids, Rock Island, or Wells) without a subsequent detection at Prosser or Roza Dam. For coded-wire tagged fish, a stray is generally defined as a tag recovery in tributaries of the Columbia River upstream (and including the Snake River Basin) of its’ confluence with the Yakima River. Marked (adipose fin clipped) fish are occasionally found during carcass surveys in the Naches River system. All marked fish observed in spawning ground carcass surveys in the Naches Basin are assumed to be CESRF fish and are used to estimate in-basin stray rates.
Table 32. Estimated number of PIT- and CWT-tagged CESRF fish not returning to the Yakima River Basin (strays), and marked fish sampled during spawner surveys in the Naches Basin, per number of returning fish, brood years 1997-present.

| $2011{ }^{2}$ | 181 | 28 | 15.47\% | 3,607 | 15 | 0.42\% | 2,340 |  |  |
| $2012{ }^{2}$ | 69 | 13 | 18.84\% | 1,713 | 16 | 0.93\% | 1,492 |  |  |
| 2013 | 152 | 4 | 2.63\% |  |  |  |  |  |  |

${ }^{1}$ All marked fish observed in spawning ground carcass surveys in the Naches Basin are assumed to be CESRF fish.
${ }^{2}$ Water temperature in the lower Yakima River was greater than $70^{\circ} \mathrm{F}$ for much of the late spring/summer migration in 2015 which likely caused many fish returning that year (BY2011 age-4 and BY2012 age-3) to seek cooler water in other parts of the Columbia Basin.

## CESRF Spawning and Survival

As described earlier, a portion of natural- and hatchery-origin (NoR and HoR, respectively) returning adults are captured at Roza Dam during the adult migration and taken to the CESRF for broodstock and/or research purposes. Fish are held in adult holding ponds at the CESRF from capture in the spring and summer until spawning in September through early October. All mortalities during the holding period are documented by sex and origin. During the spawning period data are kept on the number of males and females of each origin used for spawning or other purposes. All females have samples taken that are later evaluated for presence of BKD-causative agents. Eggs from females with high BKD-presence indicators are generally excluded (see Female BKD Profiles). Once fertilized, eggs are placed in holding troughs until shock time. Dead eggs are then sorted and hand-counted. All live eggs are machine counted, sorted into two lots per female (treatment and control) and placed into incubation (heath) trays. Using hand counts of egg samples from a subsample of female egg lots, WDFW staff determined that machine counts are biased and that the best approximation of live egg counts is given by the following equation:
$\left(\left(\frac{\text { no. eggs in subsample }}{\text { wt. of subsample }} *\right.\right.$ total egg mass wt $\left.) * 0.945\right)$ - dead eggs
where
the first 3 parameters are from egg samples taken from females at spawn time, dead eggs are the number of dead or unfertilized eggs counted at shock time, and the 0.945 value is a correction factor from 1997 and 2000 WDFW studies.

Total egg take is calculated as the total number of live eggs, dead eggs, and all documented egg loss (e.g. spilled at spawn time, etc.). Heath trays are periodically sampled during incubation and dead fry are culled and counted. The number of live eggs less documented fry loss is the estimate of the number of fry ponded. Once fry are ponded, mortalities are counted and recorded daily during the rearing period. Fish are hand counted in the fall prior to their release as they are 100-percent marked. This handcount less documented mortalities from marking through release is the estimate of smolts released. Survival statistics by origin and life-stage are given in Tables 33 and 34.

Table 33. Cle Elum Supplementation and Research Facility spawning and survival statistics (NoR brood only), 1997 - present.

1. Total collected minus total mortalities does not equal total spawned. This is because some fish are used in the spawning channel, some have been released back to the river, and some have not been used.
2. Includes jacks.
3. All documented egg loss at spawn time plus dead eggs counted at shock divided by the estimated total egg take.
4. Based on physical counts at mark time and all documented rearing mortality from ponding to release, except for BY2013 it is live eggs (est.) minus fry loss.
5. Approximately one-half of these were jacks, many of which were not used in spawning.
6. Approximately 45,000 smolts lost at Jack Creek due to frozen equipment in February, 2006.
7. EWOS feed treatment had high mortality and was discontinued in May 2007; resulted in lower survival to release.
8. Approximately 36,000 NoR (Table 33) and 12,000 HoR (Table 34) fish were culled in July 2009 to reduce pond densities; these fish were added back in to fry-smolt and live-egg-smolt survival calculations.
9. Table 34 -- From 2002 to present this is the estimated total egg take from all HxH crosses. Due to the large surplus of eggs over the approximately 100 K needed for the HxH line, many surplus fry were planted in nearby land-locked lakes and some surplus eggs were destroyed.
10. Table 34 -- For only those HxH fish which were actually ponded.

See footnotes for Table 33 above.

## Female BKD Profiles

Adults used for spawning and their progeny are tested for a variety of pathogens accepted as important in salmonid culture (USFWS Inspection Manual, 2003), on a population or "lot" basis. At the CESRF, and in the Columbia Basin it has been accepted that the most significant fish pathogen for spring Chinook is Renibacterium salmoninarum, the causative agent of Bacterial Kidney Disease (BKD). All adult females and 30-60 juveniles from each acclimation pond are individually tested for levels of Renibacterium salmoninarum using ELISA (Enzyme linked Immuno-sorbant Assay). ELISA data are reported annually to CESRF and YKFP staff for management purposes, eventual data entry and comparisons of ponds and rearing parameters. To date, no significant occurrences of other pathogens have been observed. Periodic field exams for external parasites and any signs of disease are performed on an "as needed" basis. Facility staff have been trained to recognize early signs of behavior changes or diseases and would report any abnormalities to the USFWS, Olympia Fish Health Center for further diagnostic work.

Adult females are ranked from 0 to 13 based on the relative amounts of BKD in the tissue samples of the tested fish. All BKD ranks below 5 are considered low risk for transferring significant BKD organisms through the egg to cause significant disease in progeny receiving proper care. The progeny of adults with BKD rank 6 are considered to be moderate risk and those with BKD rank 7 or greater are considered to be high risk. Given these data, the CESRF chose to rear only the progeny of females with a BKD rank of 6 or less through brood year 2001. Beginning with brood year 2002, the progeny of fish with BKD rank 6 (moderate risk) or greater (high risk) have not been used for production purposes at the CESRF. For additional information, see Appendix B.

Figure 4. Proportion of wild/natural females spawned at CESRF by BKD rank, 1997 - present.

## Fecundity

Fish collected at Roza Dam are taken to the CESRF for spawning and/or research purposes. Egg loss due to spill or other reasons at spawn time is documented. When eggs are shocked, unfertilized (dead) eggs are hand-counted and remaining eggs are machine counted. Due to error associated with machine counts, average fecundity is calculated using spawn-time egg sample data (see discussion above under CESRF Spawning and Survival) and adding in documented egg loss for all females divided by the number of females $(\mathrm{N})$ in the sample.

Table 35. Mean fecundity by age of adult females (BKD rank < 6) spawned at CESRF, 1997-present.

| Brood Year | Wild/Natural (SN) |  |  |  |  |  | CESRF (HC) |  |  |  |  |  |

1. Given their length and fecundity, these fish may have been incorrectly aged.

## Juvenile Salmon Evaluation

## Food Conversion Efficiency

At the end of each month that fish are in the rearing ponds at the CESRF or the acclimation sites, a sample of fish are weighed and measured to estimate growth. These data, in addition to monthly mortality and pond feed data are entered into the juvenile growth and survival tracking database. Hatchery managers monitor food conversion (total pounds fed during a month divided by the total pounds gained by the fish) to track how well fish are converting feed into body mass and to evaluate the amount of feed that needs to be provided on a monthly basis. Average monthly food conversion and growth statistics for the CESRF facilities by brood year are provided in the following tables and figures.

Table 36. Mean food conversion (lbs fed/lbs gained) of CESRF juveniles by brood year and growth month, 1997 - present.

| Brood <br> Year | Apr | May | Jun | Jul | Aug | Sep | Oct | Nov | Dec | Jan | Feb | Mar |

## Length and Weight Growth Profiles

Figure 5. Mean length (cm) of "standard growth treatment (Hi)" CESRF juveniles by brood year and growth month, 1997 - present.

Appendix B. Yakima River / CESRF Spring Chinook Salmon - Yakama Nation Data Summary 2017 Annual Report, May 31, 2018

Figure 6. Mean Weight (fish/lb) of "standard growth treatment (Hi)" CESRF juveniles by brood year and growth month, 1997 - present.

## Juvenile Fish Health Profile

Approximately 5-60 fish from each acclimation site pond were sacrificed for juvenile fish health samples in the spring (usually in March) of their release year. Tissue samples from these fish were processed at USFWS laboratories in Olympia, Washington for presence of bacterial kidney disease (BKD) using enzyme-linked immunosorbent assay (ELISA) tests (see Female BKD Profiles and Appendix B for additional discussion). Fish were ranked from 0 to 13 based on the relative amounts of BKD in the tissue samples of the tested fish. Based on empirical evidence, fish with BKD ranks of $0-5$ were considered to be low risk for incidence of BKD in the presence of a good fish culture and rearing environment (i.e., water temperature and flows, nutrition, densities, etc. all must be conducive to good fish health). Mean BKD ranks for all juvenile fish sampled ranged from 0.11 to 3.32 for the 17 brood years when adequate samples were available (Table 37), indicating that juvenile fish released from the CESRF appear to be well within the low risk category for all release years to date.

Table 37. Mean BKD rank of juvenile fish sampled at CESRF acclimation sites by brood year, 1997-present.

| Brood <br> Year | Acclimation Site |  |  |  |  |

1. For the 1999, 2004 and 2005 broods, antibody problems were encountered and the USFWS was unable to process the samples.

## Incidence of Precocialism

For brood years 2002-2004, the YKFP tested two different feeding regimes to determine whether a slowed-growth regime reduces the incidence of precocialism without a reduction in postrelease survival. The two growth regimes tested were a normal (High) growth regime resulting in fish which were about 30/pound at release and a slowed growth regime (Low) resulting in fish which were about 45/pound at release. As a critical part of this study, a team from NOAA Fisheries conducted research to characterize the physiology and development of wild and hatchery-reared spring Chinook salmon in the Yakima River Basin. While precocious male maturation is a normal life-history strategy, the hatchery environment may be potentiating this developmental pathway beyond natural levels resulting in potential loss of anadromous adults, skewing of sex ratios, and negative genetic and ecological impacts on wild populations. Previous studies have indicated that age of maturation is significantly influenced by endogenous energy stores and growth rate at specific times of the year. These studies will help direct rearing strategies at the CESRF to allow production of hatchery fish with physiological and life-history attributes that are more similar to their wild cohorts.

## CESRF Smolt Releases

The number of release groups and total number of fish released diverged from facility goals in some years. In brood year 1997, the Jack Creek acclimation facility was not yet complete and project policy and technical teams purposely decided to under-collect brood stock to allow a methodical testing of the new facility's operations with less risk to live fish, which resulted in the stocking of only 10 of the 18 raceways. In brood year 1998, the project did not meet facility release goals due to a biological specification that no more than $50 \%$ of returning wild fish be taken for brood stock. As a result only 16 raceways were stocked with progeny of the 1998 brood. In the same year, raceway 4 at the Jack Creek acclimation site suffered mechanical failures causing loss of flow and reduced oxygen levels and resulted in the loss of approximately one-half the fish in this raceway prior to release. In the drought year of 2001, a large number of returning adults presented with high enzyme-linked immunosorbent assay (ELISA) levels of Renibacterium salmoninarum, the causative agent of bacterial kidney disease (BKD). The progeny of these females were purposely destroyed. As a result, only nine raceways were stocked with fish. The project decided to use the fish from an odd raceway for a predator avoidance training sub-experiment (these fish were subsequently acclimated and released from the Easton acclimation site).

1. Brood years 1997-2001: Optimum Conventional Treatment (OCT). Brood Years 2002-2004: Normal (High) growth. Brood Years 2005-2012: Normal feed at Cle Elum or accl. sites.
2. Brood years 1997-2001: Semi-natural Treatment (SNT). Brood Years 2002-2004: Slowed (Low) growth. Brood Year 2005, 2007-2012: saltwater transition feed at accl. Sites; BY2014-present: BioPRO vs BioVIT diet. Brood Year 2006: EWS diet at CESRF through May 3, 2007.
3. At the Jack Creek acclimation site only 4 of 6 raceways were stocked, and raceway 4 suffered mechanical failures resulting in the loss of about 20,000 OCT (control) fish.
4. High BKD incidence in adult broodstock reduced production to just 9 ponds (Clark Flat 1-2, Jack Creek, and Easton). Easton ponds were used for predator avoidance trained (PAT) fish and a single Cle Elum pond was spread between 6 ponds at Easton with crowders used to simulate pond densities for fish at other acclimation sites. These releases were excluded from mean pond density calculations by treatment.
5. At the Jack Creek acclimation site raceway 3 suffered mechanical failures resulting in the loss of about 45,000 high-growth (control) fish.

Mean length and weight at release by brood year are shown in Figures 5 and 6 under Juvenile Salmon Evaluation, length and weight growth profiles. Mark information and volitional release dates are given in Appendix A.

## Smolt Outmigration Timing

The Chandler Juvenile Monitoring Facility (CJMF) located on the fish bypass facility of Chandler Canal at Prosser Dam (Rkm 75.6; Figure 1) serves as the cornerstone facility for estimating smolt production in the Yakima Basin for several species and stocks of salmonids. Daily species counts in the livebox at the CJMF are expanded by the canal entrainment, canal survival, and sub-sampling rates in order to estimate daily passage at Prosser Dam (Neeley 2000). Expansion techniques for deriving Chandler smolt passage estimates are continually
being reviewed and revised to incorporate new information. A subset of fish passing through the CJMF is sampled for presence of internal (CWT or PIT) or external (fin-clip) marks. All fish with marks are assumed to be of hatchery origin; otherwise, fish are presumed to be of natural origin.

Figure 7. Mean flow approaching Prosser Dam versus mean estimated smolt passage at Prosser of aggregate wild/natural and CESRF spring Chinook for outmigration years 1999-2017.

## Smolt-to-Smolt Survival

OCT-SNT Treatment (Brood Years 1997-2001, Migration Years 1999-2003)
Results of this experiment have been published:
Fast, D. E., D. Neeley, D.T. Lind, M. V. Johnston, C.R. Strom, W. J. Bosch, C. M. Knudsen, S. L. Schroder, and B.D. Watson. 2008. Survival Comparison of Spring Chinook Salmon Reared in a Production Hatchery under Optimum Conventional and Seminatural Conditions. Transactions of the American Fisheries Society 137:1507-1518.

Abstract — We found insufficient evidence to conclude that seminatural treatment (SNT; i.e., rearing in camouflage-painted raceways with surface and underwater structures and underwater feeders) of juvenile Chinook salmon Oncorhynchus tshawytscha resulted in higher survival indices than did optimum conventional treatment (OCT; i.e., rearing in concrete raceways with surface feeding) for the specific treatments and environmental conditions tested. We reared spring Chinook salmon from fry to smolt in paired raceways under the SNT and OCT rearing treatments for five consecutive years. For four to nine SNT and OCT raceway pairs annually, we used passive integrated transponder, coded wire, and visual implant elastomer tags to compare survival indices for juvenile fish from release at three different acclimation sites 340-400 km downstream to passage at McNary Dam on the Columbia River, and for adults from release to adult return to Roza Dam in the upper Yakima basin. The observed differences in juvenile and adult survival between the SNT and OCT fish were either statistically insignificant, conflicting in their statistical significance, or explained by significant differences in the presence of the causative agents of bacterial kidney disease in juvenile fish at release.

Two early-rearing nutritional regimes were tested using hatchery-reared Yakima Upper spring Chinook for brood years 2002 through 2004. A low nutrition-feeding rate (low treatment or low) was administered at the Cle Elum Hatchery through early rearing to determine whether that treatment would reduce the proportion of precocials produced compared to a conventional feeding rate during early rearing. The conventional feeding rate, which served as a control treatment, is referred to here as a high nutrition-feeding rate (high treatment or high). Feed was administered at a rate of 10 grams/fish for the low treatment and 15 grams/fish for the high treatment through mid-October, after which sufficient feed was administered to both sets of treated fish to meet their feeding demands. The treatments were allocated within pairs of raceways (blocks), there being a total of nine pairs. The Low nutritional feed (Low) had a significantly lower release-to-McNary survival than did the High nutritional feed (High), respective survivals being $18.1 \%$ and $21.2 \%$ ( $\mathrm{P}<0.0001$; D. Neeley, Appendix B of 2008 annual report). The Low survival to McNary was consistently lower than the High at all sites in all years. Low-treated fish were smaller fish at the time of release and had somewhat later McNary passage times than high-treated fish.

Control versus Saltwater Transfer Treatment (Brood Years 2005, 2007- 2010; Migration Years 2007, 2009-2013)

Prior to releases in 2007, 2009-2013, two feed treatments were allocated to raceways within adjacent raceway pairs. Fish from each raceway within the pairs were fed BioVita prior to smoltification, then the BioVita feed for one of the raceway pairs was supplemented with a BioTransfer diet and the other was not. The intent of the experiment was to determine whether the Transfer-supplemented-feed treatment increased the rate of smoltification, the nonsupplemented treatment serving as the control. Analyses indicated no significant or substantial differences between the supplemented and non-supplemented feed when averaged over years. See Appendix D of this annual report for additional detail.

## Control (Bio-Oregon) versus EWOS Feed Comparison (Brood Year 2006, Migration Year 2008)

This experimental design was similar to that described above for the Control versus saltwater transfer treatment study, with the standard Bio-Oregon pellets fed to half of the rearing ponds and an EWOS (www.ewos.com) diet fed to the other ponds. The different feed treatments only lasted about 6 weeks from the time of initial ponding as we found substantially higher mortalities for fish receiving the EWOS feed. From May 7, 2007 until these fish were released in 2008 all fish in this study received the Bio-Oregon diet. For the parameters of interest, we found no significant or substantial differences between the two feeding treatments (Appendix B of 2008 annual report).

## Smolt-to-Adult Survival

Calculation of smolt-to-adult survival rates for Yakima River spring Chinook is complicated by the following factors:

1) Downstream of the confluence of the Yakima and Naches rivers the three populations of spring Chinook (Upper Yakima, Naches, and American) are aggregated. A subsample of the aggregate wild/natural populations is PIT-tagged as part of the Chandler juvenile sampling operation but their origin is not known at the time of tagging. Through 2003, the primary purpose of this subsampling effort was to derive entrainment and canal survival estimates (see 2 below). Due to issues such as tag retention and population representation, adult detections of smolts PIT-tagged at Chandler cannot be used in any valid smolt-to-adult survival analyses.
2) Smolt accounting at Prosser is based on statistical expansion of Chandler smolt trap sampling data using available flow data and estimated Chandler entrainment rates. Chandler smolt passage estimates are prepared primarily for the purpose of comparing relative wild versus CESRF passage estimates and not for making survival comparisons. While these Chandler smolt passage estimates represent the best available data, there may be a relatively high degree of error associated with these estimates due to inherent complexities, assumptions, and uncertainties in the statistical expansion process. Therefore, these estimates are subject to revision. We are in the process of developing methods to subdivide the wild/natural outmigration into Upper Yakima, Naches, and American components based on DNA samples of juveniles taken at Chandler since 1998.
3) Installation of adult PIT detection equipment at all three ladders at Prosser Dam was not completed until the fall of 2005. Therefore, detection of upstream-migrating PIT-tagged adult spring Chinook at Prosser Dam was not possible for all returning fish until the spring of 2006. Periods of high flow may preclude use of automated detection gear so $100 \%$ detection of upstream migrants is not possible in all years.
4) Through 2006, detection of upstream-migrating PIT-tagged adult spring Chinook at Roza Dam occurred at an approximate $100 \%$ rate only for marked CESRF fish and wild/natural fish taken for broodstock. The majority of wild/natural fish were passed directly back to the river without PIT interrogation.
5) For the 1997 brood (1999 out-migration), 400 Khz PIT-tags were used. Mainstem detection facilities were not configured to detect these tags at nearly the efficiency that they can detect the newer 134.2 kHz ISO tags. Although all marked adult fish are trapped and hand-wanded for PIT detections of adults at Roza Dam, the reliability of the 400 kHz detection gear and problems with hand-sampling in general likely precluded a complete accounting of all 1997 brood PIT returns.
6) All CESRF fish are adipose-fin clipped and subjected to higher harvest rates than unmarked wild/natural fish in marine and Columbia River mark-selective fisheries. No adjustments have yet been made in the following tables to account for differential harvest rates in these mark-selective fisheries.
7) PIT tag retention is a factor in estimating survival rates (Knudsen et al. 2009). No attempt has been made to correct the data in the following tables for estimates of tag retention.
8) The ISAB has indicated that "more attention should be given to the apparent documentation that PIT-tagged fish do not survive as well as untagged fish. This point has major implications for all uses of PIT-tagged fish as surrogates for untagged fish." Our data appear to corroborate this point (Tables 45-46). However, these data are not corrected for tag loss. If a fish loses its PIT tag after detection upon leaving the acclimation site, but before it returns as an adult to Roza Dam, it would be included only as a release in Table 45 and only as an adult return in Table 46. Knudsen et al. (2009) found that smolt-to-adult return rates (SARS) based on observed PIT tag recoveries were significantly underestimated by an average of $25 \%$ and that after correcting for tag loss, SARS of PIT-tagged fish were still $10 \%$ lower than SARS of non-PIT-tagged fish. Thus, the data in Table 45 under-represent "true" SARS for PIT-tagged fish and SARS for PIT-tagged and non-PIT-tagged fish are likely closer than those reported in Tables 45 and 46.
9) Due to issues relating to water permitting, size required for tagging, and allowing sufficient time for acclimation, CESRF juveniles are not allowed to migrate until at least March 15 of their smolt year. However, juvenile sampling observations at Roza Dam indicate that a substantial number of wild/natural juveniles migrate downstream during the summer, fall, and winter months prior to their smolt outmigration year (Figure 7). Comparison of SAR data for non-contemporaneously migrating juveniles may be invalid (see Copeland et al. 2015).

Given these complicating factors, Tables 40-46 present available smolt-to-adult survival data for Yakima River CESRF and wild/natural spring Chinook. Unfortunately, true "apples-to-apples" comparisons of CESRF and wild/natural smolt-to-adult survival rates are not possible from these tables due to complexities noted above. The reader is cautioned to correct these data for, or acknowledge the factors noted above prior to any use of these data.

Table 40. Estimated smolt passage at Chandler and smolt-to-adult return indices (Chandler smolt to Yakima R. mouth adult) for Yakima Basin wild/natural and CESRF-origin spring Chinook.

1. Mean flow (cfs) approaching Prosser Dam March 29-July 4 of juvenile migration year. No data available for migration year 1991. In high flow years (flows at or > 5000 cfs ) operation of the Chandler smolt sampling facility may be precluded during portions of the outmigration. Data courtesy of U.S. BOR hydromet.
2. Aggregate of Upper Yakima, Naches, and American wild/natural populations.
3. Estimated smolt-to-smolt (release from upper Yakima River acclimation sites to Chandler) survival for CESRF juveniles.
4. Includes combined age-3 through age-5 returns. CESRF adult returns and smolt-to-adult survival values are understated relative to wild/natural values since these figures are not adjusted for differential harvest rates in mark selective fisheries in marine and lower Columbia River fisheries.
5. Available data were not sufficient to estimate juvenile flow-entrainment and passage of wild/natural fish.
6. Data for most recent year are preliminary; return data do not include age-5 adult fish.

Table 41. Estimated wild/natural smolt-to-adult return rates (SAR) based on adult detections of PIT tagged fish. Roza tagged smolts to Bonneville Dam adult returns. Footnotes follow Table 42.

| 2014 | 1,104 | 0 |  |  |  |  |

1. CESRF adult returns and smolt-to-adult survival values are understated relative to wild/natural values since these figures are not adjusted for differential harvest rates in mark selective fisheries in marine and lower Columbia River fisheries.
2. The reliability of the 400 kHz detection gear precluded an accurate accounting of all 1997 brood PIT returns. Therefore, this is not a true SAR. It is presented for relative within-year comparison only and should NOT be compared to SARs for other years.

Table 43. Overall wild/natural smolt-to-adult return rates (SAR) based on juvenile and adult detections of fish PIT-tagged and released at Roza Dam (Table B. 74 in McCann et al. 2017). McNary smolts to Bonneville Dam adult returns. For 2010 and 2014 migration years, few if any wild smolts were PIT-tagged at Roza.

Table 44. Overall CESRF smolt-to-adult return rates (SAR) based on juvenile and adult detections of PIT tagged fish (Table B. 78 in McCann et al. 2017). McNary smolts to Bonneville Dam adult returns.

1. When tag detection data are available, this is the number of unique PIT tags physically detected leaving the acclimation sites. Otherwise, this is the number of fish PIT tagged less documented mortalities of PIT-tagged fish from tagging to release.
2. BY1997 used 400 kHz tags and Bonneville Dam was not fully configured for adult detection of this type of tag; therefore we saw more detections at Roza Dam where fish were manually wanded for adult PIT detections.
3. Includes HxH fish beginning with this brood year.

Table 46. Estimated release-to-adult survival of non-PIT-tagged CESRF fish (CESRF tagged smolts to Roza Dam adult returns).

| 2011 | 731,017 | 780 | 2,318 | 51 | 3,149 | $0.43 \%$ |  |
| 2012 | 764,373 | 172 | 2,274 | 0 | 2,446 | $0.32 \%$ |  |
| 2013 | 608,477 | 718 | 2,398 |  |  |  |  |
| 2014 | 647,111 | 988 |  |  |  |  |  |

1. These fish were adipose fin-clipped, coded-wire tagged, and (beginning with 4 of 16 ponds in 1998) elastomer eye tagged. This is the number of fish physically counted at tagging.
2. BY1997 used 400 kHz tags and Bonneville Dam was not fully configured for adult detection of this type of tag; therefore we saw more detections at Roza Dam where fish were manually wanded for adult PIT detections.
3. Includes HxH fish beginning with this brood year.

## Harvest Monitoring

## Yakima Basin Fisheries

For spring fisheries in the Yakima River Basin, both the WDFW and the Yakama Nation employ two technicians and one biologist to monitor and evaluate in-basin harvest in the respective sport and tribal fisheries. Harvest monitoring consists of on-the-water surveys to collect catch data and to record tag information (e.g., elastomer, CWT, etc.) where possible for adipose-clipped fish. Survey data are expanded for time, area, and effort using standard methods to derive estimates of total in-basin harvest by fishery type (sport and tribal) and catch type (CESRF or wild denoted by adipose presence/absence).

Table 47. Spring Chinook harvest in the Yakima River Basin, 1984-present.

| Year | Tribal |  | Non-Tribal |  | River Totals |  |  | Harvest <br> Rate ${ }^{1}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| 2017 | 217 | 201 | 750 | $104{ }^{2}$ | 967 | 305 | 1,272 | 17.8\% |
| Mean | 540 | 672 | 576 | 88 | 1,116 | 643 | 1,172 | 13.6\% |

1. Harvest rate is the total Yakima Basin harvest as a percentage of the Yakima River mouth run size.
2. Includes estimate of post-release mortality of unmarked fish.

## Columbia Basin Fisheries

Standard run reconstruction techniques are employed to derive estimates of harvest from the Columbia River mouth to the Yakima River mouth for spring Chinook. Data from databases maintained by the United States versus Oregon Technical Advisory Committee (TAC) are used to obtain harvest rate estimates downstream of the Yakima River for the aggregate Yakima River spring Chinook population and to estimate passage losses from Bonneville through McNary reservoirs. These data, combined with the Prosser Dam counts and estimated harvest below Prosser, are used to derive a Columbia River mouth run size estimate and Columbia River mainstem harvest estimate for Yakima spring Chinook.

Table 48. Estimated run size, harvest, and harvest rates of Yakima Basin spring Chinook in Columbia River mainstem and terminal area fisheries, 1984-present.

| Year | Columbia <br> R. Mouth <br> Run Size | Col. R. Mouth to BON Harvest | BON to McNary Harvest | Yakima <br> R. Mouth <br> Run Size | Yakima <br> River <br> Harvest | Columbia Basin Harvest Summary |  |  | Col. Basin Harvest Rate |  |

Appendix B. Yakima River / CESRF Spring Chinook Salmon - Yakama Nation Data Summary

## Marine Fisheries

Based on available CWT information, harvest managers have long assumed that Columbia River spring Chinook are not harvested in any abundance in marine fisheries as the timing of their ocean migration does not generally overlap either spatially or temporally with the occurrence of marine fisheries (TAC 1997). The Regional Mark Information System (RMIS) will be queried regularly for any CWT recoveries of CESRF releases in ocean or Columbia River mainstem fisheries. Table 49 gives the results of a query of the RMIS database run on Nov. 22, 2017 for CESRF spring Chinook CWTs released in brood years 1997-2012 and Figure 8 shows recovery locations for CWTs recovered in marine fisheries 2008-2012. Based on the information reported to RMIS to date, it is believed that marine harvest accounts for about $0-3 \%$ of the total harvest of Yakima Basin spring Chinook. CWT recovery data for brood year 2012 were considered too incomplete to report at this time.

Table 49. Marine and freshwater recoveries of CWTs from brood year 1997-2012 releases of spring Chinook from the CESRF as reported to the Regional Mark Information System (RMIS) 22 Nov, 2017.

| Brood | Observed CWT Recoveries |  |  | Expanded CWT Recoveries |  |  |
| :---: | ---: | ---: | ---: | ---: | ---: | ---: |
| Year | Marine | Fresh | Marine \% | Marine | Fresh | Marine \% |
| 1997 | 5 | 56 | $8.2 \%$ | 8 | 321 | $2.4 \%$ |
| 1998 | 2 | 53 | $3.6 \%$ | 2 | 228 | $0.9 \%$ |
| 1999 |  | 2 | $0.0 \%$ |  | 9 | $0.0 \%$ |
| 2000 |  | 14 | $0.0 \%$ |  | 34 | $0.0 \%$ |
| 2001 |  | 1 | $0.0 \%$ |  | 1 | $0.0 \%$ |
| 2002 |  | 7 | $0.0 \%$ |  | 36 | $0.0 \%$ |
| 2003 |  | 4 | $0.0 \%$ |  | 10 | $0.0 \%$ |
| 2004 | 2 | 154 | $1.3 \%$ | 15 | 526 | $2.8 \%$ |
| 2005 | 2 | 96 | $2.0 \%$ | 2 | 304 | $0.7 \%$ |
| 2006 | 14 | 328 | $4.1 \%$ | 16 | 1160 | $1.4 \%$ |
| 2007 | 8 | 145 | $5.2 \%$ | 13 | 1139 | $1.1 \%$ |
| 2008 | 5 | 245 | $2.0 \%$ | 7 | 1634 | $0.4 \%$ |
| 2009 | 4 | 91 | $4.2 \%$ | 7 | 588 | $1.2 \%$ |
| 2010 | 4 | 164 | $2.4 \%$ | 9 | 942 | $0.9 \%$ |
| 2011 | 5 | 186 | $2.6 \%$ | 5 | 1019 | $0.5 \%$ |
| $2012^{1}$ | 4 | 64 | $5.9 \%$ | 2 | 261 | $0.8 \%$ |

1. Reporting of CWT recoveries to the RMIS database typically lags actual fisheries by one to two years. Therefore, CWT recovery data for brood year 2012 are considered preliminary or incomplete.

Figure 8. Marine recovery locations of coded-wire-tagged CESRF spring Chinook, recovery years 2008-2012.

${ }^{1}$ BIO = BioVita (BioOregon Protein Inc.) or control diet; STF = salt-water transition diet at acclimation sites. All fish are progeny of wild/natural parents unless denoted as HH which designates the hatchery control line beginning with brood year 2002. "Avg BKD" denotes the average BKD ELISA ranking of the female parents whose progeny were in these ponds
${ }^{2}$ The number of fish released is estimated as the total number of fish counted at marking less mortalities documented from mark to release.

"Avg BKD" denotes the average BKD ELISA ranking of the female parents whose progeny were in these ponds
${ }^{2}$ The number of fish released is estimated as the total number of fish counted at marking less mortalities documented from mark to release.

${ }^{1}$ BIO = BioVita (BioOregon Protein Inc.) or control diet; STF = salt-water transition diet at acclimation sites. All fish are progeny of wild/natural parents unless denoted as HC which designates the hatchery control line beginning with brood year 2002. "Avg BKD" denotes the average BKD ELISA ranking of the female parents whose progeny were in these ponds.
${ }^{2}$ The number of fish released is estimated as the total number of fish counted at marking less mortalities documented from mark to release

${ }^{1}$ All fish are progeny of wild/natural parents unless denoted as HC which designates the hatchery control line beginning with brood year 2002. "Avg BKD" denotes the average BKD ELISA ranking of the female parents whose progeny were in these ponds. PRO=BioPro diet, VIT=BioVita diet, Bio-Oregon products.
${ }^{2}$ The number of fish released is estimated as the total number of fish counted at marking less mortalities documented from mark to release.
${ }^{3}$ Due to problems at the acclimation site, Jack Creek raceway 6 was closed and all fish transferred and split between raceways 2 and 4 in February 2018.

## Appendix C Preliminary ${ }^{1}$ <br> 2017 Annual Chandler Certification for Yearling Outmigrating Spring Chinook Smolt

Doug Neeley, Consultant to the Yakama Nation

## Summary

Spring Chinook juvenile Prosser Passage was estimated using the following steps.

1) Estimating individual daily sampling rates from the Chandler Canal bypass;
2) Estimating detection efficiencies of the Chandler bypass detector;
3) Expanding sample-rate-adjusted daily tallies of wild and hatchery smolt sampled from the Prosser Chandler Canal bypass by daily Step 1 sample-rate estimates and then dividing that expansion by Step 2 bypass-detection efficiencies to estimate the daily Prosser passage;
4) For wild smolt, multiplying expanded wild tally-based passage estimates by estimated proportions ${ }^{2}$ of wild ${ }^{3}$ smolt that are of American, Naches, and Upper Yakima River stock origin to the their respective passage estimates.

The resulting juvenile Prosser-passage estimates are given in Table 1.A. Figure 1.A.1) presents the total wild and total hatchery Prosser juvenile passages, and Figure 1.A.2) presents separate estimates of wild Prosser passages for each stock based on the Table 1.A. data for each brood-year (BY). Adjoining Table 1.B.1) and 1.B.2) respectively give for all Prosser smolt passage and for Upper-Yakima Prosser smolt passage the percentage wild and hatchery contributions to those respective stock based on data presented in Table 1.a.. Figures 1.B.1) and 1.B.2) plot the respective passages from those adjoining

[^11]tables. Table 1.C. and Figure 1.C. presents the proportional contributions of the three stock to the total wild passage, again based on data presented in Table 1.A.

* Standard Wild estimate is tally of sampled non-PIT-tagged smolt divided by stratified detection efficiency base on detections of Prosser PIT-tagged smolt subsequently detected at McNary, John Day, and Bonneville Dams.
** Standard Hatchery estimate is based tallies of sampled smolt at Prosser that were elastomer-tagged at the hatchery divided by proportion of hatchery smolt that were elastomer tagged (all hatchery smolt have been coded-wire tagged and have been either elastomer-tagged or PIT-tagged).
*** Estimate may be biased for issues discussed later in this report.
**** Standard estimate is biased with hatchery smolt estimate of 1,728,858 smolt nearly 2.5 times the number $(685,230)$ of hatchery smolt released, and wild estimate is highest of all years. Alternative calibrated estimate is used that was based on number smolt detected in the Prosser bypass that were PIT-tagged at the hatchery divided by proportion of hatchery smolt that were PIT-tagged tagged for both wild and hatchery smolt.

All methods of estimation are discussed in subsequent sections of this report.

Figure 1.C. Proportional Stock-Origin Contribution to Wild Passage

A major finding from the analysis presented in this report is that more than $60 \%$ of the total variance in wild returns over years is associated with the number of those fish outmigrating as juveniles.

## Methodology

The four steps listed in the summary are detailed below.

Step 1: A timer gate, when opened, directs the bypass flow into the facility where smolt are tallied. The timer-gate rate (TR) settings vary over days based on the number of the sampled smolt entering the counting facility so as to not to overwhelm the capacity of the facility or the ability of the staff to tally those smolt by species and stock. For each timer-rate setting, the sample rate (SR) is computed by dividing the number of PIT-tagged Spring Chinook smolt detected in the sampling facility by the total number detected by a bypass detector located upstream of the timer gate. The sample-rate estimates for each timer-gate rate setting are presented for each year in Appendix A.

Step 2: The proportions of all PIT- tagged smolt released above Prosser and detected at mid-Columbia dams ${ }^{4}$ that were previously detected in the Chandler Canal bypass serve as estimates of bypassdetection efficiency. There are four methods of estimating detection efficiency which are discussed in the next section. One the these methods has been selected based on findings contained in this report and is now being used for smolt-smolt release-to-McNary survival estimates for Coho and Spring, Fall, and Summer Chinook in other reports.

Step 3: On a daily basis the sampled Spring Chinook smolt were tallied as to source (hatchery-spawned or wild). On those days when the facility was shut down, linear interpolation was used to impute values to this missing information. The daily actual and imputed tallies were divided by the sample rates from Step 1. The sample-rate adjusted tallies for each source were added over days within each of five time periods (discussed under Step 4) and were then divided by the respective period's detection efficiencies from Step 2. The wild and hatchery smolt were tallied separately. The wild smolt were identified by the

[^12]lack of a coded-wire tag. The hatchery smolt were identified by the presence of an elastomer tag. The detection-efficiency-adjusted hatchery tallies were the divided by the proportion of hatchery smolt that were elastomer tagged.

In the case of the 2016 passage, the hatchery estimates were clearly biased in that the passage estimates exceeded the number of hatchery smolt released (implying that the wild estimates were also biased). An alternative method was used: Daily PIT-tag detection counts from the bypass detector were expanded by the detection efficiencies. Since the bypass detector was located above the timer gate, both sampled and not-sampled smolt were detected and no sample-rate expansion was required ${ }^{5}$. The detection-efficiency-expanded tallies were then divided by the proportion of smolt PIT-tagged at the hatchery. All hatchery smolt were CWT-tagged and also had either an elastomer tag or a PIT-tag but not both.

Step 4: Within five time periods (pre-March, March, April, May, post-May), the wild smolt from Step 3. were subsampled and genetically assessed by the Molecular Genetics Lab of the Washington Department of Fish and Wildlife (WDFW) as to brood origin (stock from the American, Naches, and Upper Yakima Rivers). Within each period, the brood proportions of those sampled smolt were computed by WDFW (Appendix B.). The wild passage estimates within each period from Step 3 were multiplied by each of the period's brood-source proportions. The brood's time-period wild passage estimates were then added over the time periods to estimate brood's total passages as were the hatchery passage estimates.

In the case of the 2016 PIT-tag-based estimates, it was necessary to compute the ratios between the hatchery elastomer-based passage estimates and the hatchery PIT-tag-based estimated, and use those ratios to calibrate the wild-tally estimates which were derived from sampled smolt. The elastomerbased estimates are referred to as Expanded estimates and the PIT-tag-based estimates are referred to as Calibrated estimates. This procedure was actually performed for all broods, not only the 2016 brood.

Table 2.A. and 2.B. present the estimates from the four estimates for Hatchery and Wild smolt, respectively. Note that the shaded brood-year estimates for Expanded estimates are impossibly large, exceeding the number of smolt released. For Wild Smolt, the Expanded passage estimates in Table 2.B.1) for the two stratified elastomer estimators [column 1.a) and 1.c)] are the largest estimates over brood years and they are among the two or three largest for the two unstratified estimates [column 1.b) and 1.d)], suggesting the wild passage estimates may be overestimates as well. Detailed Expanded and Calibrated summaries for all stock are presented in Appendix C.

| 2). Calibrated Total Wild Juvenile Passage at Prosser <br> based on four methods of estimating Prosser bypass <br> detection efficiency estimated from detections in bypass <br> and at mid-Columbia dam detections |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: |

* Detection (DE) efficiency based on only McNary Dam
** DE based on pooled Estimates from McNary, John Day, and Bonneville Dams
*** Stratified by similar Prosser daily detection efficiency rates at the three Columbia River dams
**** No stratification: DE = (Total joint Prosser and lower dam detections)/(Total lower dam detections)

## Wild Passage Estimators' Correlations with Returns

To ascertain which of the passage estimates is the "best", the decision was made to correlate total Wild juvenile Prosser passage with estimates of total return from the report 2017 Run Size Forecast for Yakima River Adult Spring Chinook, tables from which are referenced herein as "Forecast Tables"

The initial evaluation is based on the correlations between the estimated total wild juvenile Prosser passage with the estimated total wild returns to Prosser (derived from Forecast Table 3) produced by that brood's outmigration. There were no separate listings for Age-4 through and Age-6 returns in the Forecast Table 3.; therefore the assignment of the non-Age-3 returns to brood years will be biased.

The respective data sets used for the Expanded and Calibrated correlations are presented in Table 4.A. and Table 4.B. along with Pearson's Correlation Coefficient estimates over brood-years 1997-2013. For reference purposes, relative values of estimated values of Pearson's Correlation Coefficients are classified based on Table 3.

Table 3. Correlation Coefficient (r) range

| Very High | 0.90 | $\leq r \leq$ | 1.00 |
| :---: | :--- | :--- | :--- |
| Moderately High | 0.75 | $\leq r<$ | 0.90 |
| Moderate | 0.25 | $\leq r<$ | 0.75 |
| Moderately Low | 0.10 | $\leq r<$ | 0.25 |
| Very Low | 0.00 | $\leq r<$ | 0.10 |

The correlations of the Expanded estimates in Table 4.A. are similar to the Calibrated estimates in Table 4.B., and the correlations of the stratified estimates (yellow shaded) are uniformly higher than the unstratified (unshaded). For the Table 4.A. yellow-shaded stratified Expanded estimates, the correlation coefficient estimates based on McNary-Dam-only detection efficiencies was slightly less than that based on pooled detection efficiencies over McNary, John Day, and Bonneville dams. The opposite was true for the Calibrated estimates; for the Table 4.B. yellow-shaded stratified Calibrated estimates, the correlation coefficient estimates based on McNary-Dam-only detection efficiencies was slightly greater than that from the pooled dam estimates.

| Correlation: Prosser Returns |  | 0.7859 | 0.7094 | 0.7845 | 0.7417 |  |  |

* Detection (DE) efficiency based on only McNary Dam
** DE based on pooled Estimates from McNary, John Day, and Bonneville Dams
*** Stratified by similar daily detection efficiency rates from Columbia River dams periods at Prosser
**** No stratification: DE = (Total joint Prosser and lower dam detections)/(Total lower dam detections)

Note that the measurable biased estimates for BY-2014 in Tables 4.a. and 4.b. did not enter into the above correlation estimation because the return information at this writing did not include non agethree returns. There is evidence of bias for the first brood (BY-1997) using all methods of estimation that will be discussed later in this report.

The decision was made to use as a standard estimate the Expanded estimates based on stratified pooled-over-dam detection efficiencies. It had a slightly higher correlation estimate (Column 3 of Table 4.A.) than the other stratified estimates.

## Adjusting Effect of Wild Juvenile Passage Estimate's Correlation with Return for the effect of Spawner Number

The effect of the spawner number on wild juvenile Prosser passage and return is assessed. Table 5.A. presents the brood-year Upper Yakima (Roza) escapement ${ }^{6}$ of the parental generation in addition to juvenile Prosser passage and Roza return. Table 5.B. presents the correlations among these three variables. Table 5.C. presents the partial correlation between the juvenile passage and associated return adjusted for escapement. The issue of bias associated with the assignment of non-Age-3 adults from Forecast Table 4. (mentioned earlier) is minor, because the vast majority of Upper Yakima returns are Age-3 and Age-4 returns with very few returns greater than Age 4.

From Tables 5.B., it can be seen that Upper Yakima returns are positively correlated to both the number of spawners and the juvenile passage. The question is to what degree, if any, is the contribution of Juvenile passage to return affected by the brood's spawner number. Table 5.C. is an attempt to answer that question. Using the parental generation escapement as an indicator of spawner number, the table adjusts the correlation between juvenile passage and return for escapement. The adjusted correlation of juvenile passage with return number is hardly affected by spawner number, the rounded moderatelyhigh correlations being 0.80 (Table 5.B.) and 0.79 (Table 5.C.) for the respective unadjusted and adjusted estimates. This indicates that the moderately high Upper Yakima juvenile Prosser passage correlation with return is not indirectly tied to the number of naturally spawning brood fish that produced those juveniles. The brood years with the highest juvenile Prosser passage (BY 1997 and BY 2000) had respectively the third highest and the second highest returns and made the greatest contribution to the magnitude of the correlation. Also given in Tables 5.B. and 5.C. are the correlation estimates with those brood years removed. The respective correlation estimates with return non-adjusted and adjusted for escapement were moderate and significantly greater than 0.

Figure 2. plots the Juvenile passage and return and indicates the similarity between their trends over brood-years. Note from this plotting that the trends over brood years of the Juvenile Prosser passage and Roza return numbers are very similar.

YKFP Project Year 2017 M\&E Annual Report, Appendix C

A similar assessment was made on total wild juvenile passage and Prosser return which is more subject to the greater-than-Age-3 brood-year -assignment bias issue. Analogous summaries are given in Tables 6.A. through 6.C and in Figure 3. with similar correlation coefficient estimates non-adjusted and adjusted for escapement (rounded 0.81 and 0.80, respectively). Again, brood years 1997 and 2000) were removed, brood year 1999 having the highest juvenile passage and return estimates, and brood year 2000 having the second highest. The resulting respective juvenile passage correlations with return were again moderate (rounded 0.48 for both the estimates non-adjusted and adjusted for escapement) and significantly greater than 0 . However, the percentage of brood years with similar juvenile passage and return trends was lower and not significantly different than $50 \%$ (Figure 2.) .

| 1-sided $P$ | 0.1051 |

The magnitudes of the juvenile passage and return correlations in both sets of Table 5. and Table 6. Summaries are worth emphasizing. They indicate that more than $60 \%$ of the total variance in wild returns over years is associated with the number of those fish outmigrating as juveniles.

Assessments are also made of the correlations between Upper-Yakima hatchery juvenile passage at Prosser and their return to Roza Dam. The spawner number per raceway is fixed, so an adjustment of the correlation between juvenile passage and return for spawner number has no inherent meaning; in fact, had the number of raceways been constant over all brood years, there would have been a constant number of spawners over brood years, and there would have been no correlation of spawners with passage or return. The decision was made to include release number to adjust for pre-release mortality. Referring to Tables 7.A. through 7.C. and Figure 4., all correlation coefficient estimates were low to moderately low and not significantly different than zero. Note from Figure 4, that only $56 \%$ of the year-to-year trends are the same for juvenile passage and return.

## Hatchery Estimates and Evidence of Bias

There is evidence of bias in juvenile passage in some years. Table 8.A. presents Expanded stratified estimates of Hatchery Prosser-to-McNary survival computed by taking estimates of Release-to-McNary Survival from other reports.

The resulting 1999-outmigrant estimator based on stratified detection efficiency estimates pooled over down-stream dams gave a 101\% Prosser-to-McNary survival estimate (Table 8.A. Brood Year 1997 Column 5 estimate). Estimates of 1999-oumigrant estimators based on the other three detection efficiency estimators gave even higher estimates of Prosser-to-McNary survivals (not presented in this report). The 1999 Release-to-McNary survival estimate is the highest over all years, and the estimated Wild juvenile passage past Prosser is also the highest [Table 1.A. and Figure 1.A.1)]. The high release-toMcNary survival may not be the main cause of the impossibly high Prosser-to-McNary estimate. The proportion of PIT-tagged hatchery smolt detected in the Prosser bypass that were previously detected leaving acclimation sites should be comparable to the proportion of PIT-tagged smolt detected leaving the acclimation sites. This is true for all years except for 1999 outmigrants (Table 8.A. Column 7 value $=$ 0.243 versus Column 8 value $=0.998$ ). This may indicate that the bias in the Prosser-to-McNary survival estimates is associated with Prosser detection issues and not due to the other variables used to estimate release-to-McNary survival. In any case, the 1999 passage estimate should be regarded as biased.

Then there is the issue with the 2016 outmigration estimate alluded to earlier. The estimate of 2016 Release-to-Prosser survival is $252 \%$ (Table 8.A. Brood Year 2014, Column 5 estimate); i.e., the estimated passage is over 2.5 times greater than the number of smolt released. In this case the problem may again be a Prosser issue. Column 10 of Table 8.a. gives the total detections when the Timer-Gate (TR) settings were at $33 \%$ and $50 \%^{7}$. That number of 2016 sample-room detections was extremely low (620), though the 2017 number was even lower, and the TR settings were the only ones for which fish were run through the sample room detector in 2016. The decision was made to use the comparable Calibrated estimate of juvenile passage (Brood Tear 2014, Column 1, Table 8.B.) which did not rely on the Prosser sampling rate and which did not give an impossibly high Release-to-Prosser survival estimate. We should note that the 2016 estimate was not used in the juvenile-passage correlation estimates with return because greater-than-age-3 are not yet available.

However, there were more problems with Calibrated estimates of Prosser hatchery juvenile passage than was the case for Expanded estimates, the Calibrated estimates (Table 8.B.) having higher than $100 \%$ Prosser-to McNary in three outmigration years, 1999 with even greater Prosser-to-McNary survival than the Expanded estimate of Table 8.A., and 2003 and 2010 in which the estimated release-to-McNary survivals were extremely low leading to McNary-to-Prosser survival exceeding $1000 \%$ which was the major reason for rejecting the Calibrated estimates being used as a standard estimate.

The yellow-shaded estimates of passage in Column 1 of Table 8.A. were used as was the yellow-shaded estimate in Columns 1 of Table 8.C.; those being the estimates given in Table 1.A. and used for Tables 1.B. and 1.C. and their associated figures.

* The calibration value = (total of TR-33\% and TR-50\% sample-facility detections)/(total of TR-33\% and TR-50\% bypass detections)
** SR estimate $=\left(\right.$ Calibration Rate) ${ }^{*}$ (Column header TR) except for TR = 1.0 which is actual sample-room estimates pooled over years
*** SR,TR rate extremely low
**** When SR estimates exceed $33 \%$ for TR $=\mathbf{3 3 \%}$, $\operatorname{SR}$ is equated to TR

# Appendix D <br> Annual Report: Smolt Survival to McNary Dam of 1999-2013 and 2015-2017 PIT-tagged Spring Chinook released at Roza Dam 

Doug Neeley, Consultant to the Yakama Nation

## Introduction and Summary

From $1999^{1}$ through 2013 and 2015-2017, survival estimates to McNary Dam (McNary) of PIT-tagged hatcheryreared (hatchery) and naturally reared (natural) Spring Chinook smolt released into the Roza Dam (Roza) juvenile bypass system were made and compared. These releases were not made in 2014 because of radio-tagged studies conducted at Roza in that year. Radio-tag studies were also conducted in 2016 as well, but there were a limited number of days when PIT-tagged releases were made, enabling estimation of Roza-to-McNary survivals based on relatively small releases numbers. The estimated 2017 McNary passage estimates of natural smolt was the smallest over all years.

Roza-to-McNary survival estimates are compared between PIT-tagged hatchery smolt and PIT-tagged natural smolt contemporaneously released with hatchery smolt at Roza, the contemporaneously released natural smolt being referred to as "late" natural smolt. Survival-estimate comparisons are also made between late and "early" natural smolt, the early natural smolt being those released before the first release of PIT-tagged hatchery-smolt at Roza. All smolt releases in this study were originally collected from the Roza bypass system, PIT-tagged if not previously PIT-tagged, and then all PIT-tagged fish were released back into the bypass.

For the contemporaneous late releases, the pooled ${ }^{2}$ mean McNary survival of late natural smolt over years is significantly and substantially greater than that of hatchery smolt; however, the 2017 survival of natural smolt was half that of hatchery smolt. The pooled survival of late released natural smolt is also greater than early released smolt, the two-sided test of that survival difference is significant at the $10 \%$ level but not at the $5 \%$ level; however, the survival of early released smolt may be underestimated in some years if some of those smolt pass McNary before the McNary bypass is watered up, in which case those smolt would not be detected.

## Methodology

All smolt releases included in the analyses were grouped into seven-day intervals; i.e., smolt released between Julian dates 1 and 7 were treated as one release group, those released between Julian dates 8 and 14 were treated as another group, etc. These groups are referred to as Julian weeks. This was primarily done to have consistency over years, but if there were not a sufficient number of smolt within a Julian week, then adjacent seven-day groups were sometimes combined into a common group. Weighted logistic analyses of variation over years were used to analyze the proportion surviving ${ }^{3}$ to McNary, their weights being the release numbers of fish used to estimate the proportions. Comparisons of late-natural and hatchery smolt were pooled over those Julian-week periods that had

[^18]both natural and hatchery smolt to insure that comparisons were true paired comparisons. If only one of those stock was released within a given Julian-week period, it was not included in the formal statistical analysis; however survival estimates from the excluded period are presented in the report. Comparisons between early and late natural smolt proportions were treated as independent (not paired) comparisons since they involved different Julian-week periods.

## Comparison of Natural-Origin and Hatchery-Origin Smolt Survival to McNary from Contemporaneous Roza Releases

Unlike most years, late naturally-reared smolt released at Roza in 2017 had a substantially lower Roza-to-McNary survival rate than did hatchery smolt. From the total of 181 released natural smolt in 2017, there were only three detections ${ }^{4}$ of natural smolt at McNary. Table 1.a. and Figure 1. present the pooled natural- and hatchery-smolt survival estimates of all late released smolt within release years.

Figure 1. Upper-Yakima Spring-Chinook Roza-to-McNary Smolt-to-Smolt Survival for Late Natural Smolt (solid lines and filled diamonds) and Hatchery Smolt (dashed lines and clear squares)

As can be seen from Table 1.a. and Figure 1, the late natural smolt survival exceeded that of the hatchery smolt in 14 or $78 \%{ }^{5}$ of the 18 outmigration years.

Because naturally-spawned smolt will have survived the in-stream environment longer than hatchery-spawned smolt by the time that they pass Roza Dam, it has always been hypothesized that, for smolt contemporaneously released at Roza, the survival to McNary of naturally-spawned-smolt would be greater than that of hatchery-spawned smolt even though the hatchery smolt tend to be larger. Therefore, a one-sided test for the hypothesis

[^19]natural survival - hatchery survival >0
was performed based on the null hypothesis of no survival difference.
To give a valid paired comparison, the hatchery recoveries from the Julian-week periods were removed from the analysis for those periods within which there were no natural releases. The modified database used is given in Table 1.b. with survivals which were modified being highlighted in yellow. The survival estimates that were altered from those given in Table 1.a. are highlighted in yellow in Table 1.b. A logistic analysis of variation resulted in the natural survival pooled over years being highly significantly greater than the pooled hatchery survival ( $\mathrm{P}=0.0013$ from Table 1.c.).

## Comparison of Early and Late Natural-Origin Smolt Survival to McNary

There were no early naturally-spawned smolt releases at Roza prior to Roza passage of hatchery smolt in 1999, 2010, and 2016; and, as stated before, there were no PIT-tagged releases in 2014. Table 2.a. and Figure 2. present the naturally-spawned early- and late-smolt survivals from Roza to McNary for those outmigration years for which early arriving natural-origin smolt were available for PIT-tagging.

Table 2.a. Upper-Yakima Spring-Chinook Roza-to-McNary Smolt Survival for Early and Late ${ }^{6}$ Natural Smolt

Figure 2. Upper-Yakima Spring-Chinook Roza-to-McNary Smolt-to=Smolt Survival for Early Natural Smolt (solid lines and filled diamonds) and for Late Natural Smolt (dashed lines and clear squares)

Of the 15 years with early releases, late releases had higher Roza-to-McNary survival in $10\left(67 \%^{7}\right)$ of those years. While the pooled mean survival estimate over years was also not significant at the $5 \%$ level ( $\mathrm{P}=0.0972$, Table 2.b.), it was significant at the $10 \%$ level. The McNary Dam’s bypass is generally watered up after mid-March. It may well be that many of the early releases pass McNary before they could be detected at McNary, in which case the early-release survival estimates presented herein may be underestimated. The actual survival early and late Julianrelease dates are delineated in Appendix A.

## Figures for all Julian Period Survivals

Figure 3. presents the individual year Prosser-to-McNary Dam Plots within Julian-week groupings for natural and hatchery releases at Prosser. As can be seen in those individual year plots, in some years the first early releases are made before the first Julian week of the stated out-migration year, and in most years the first early natural release date is before the Julian week beginning on Julian date 47. McNary Dam's bypass is generally watered up after Julian date 90. It may well be that many of the early releases pass McNary before they could be detected, in which case early-release survival estimates may be underestimated. The survival estimates are presented in Figure 3. and the survival estimates for early natural and late natural and hatchery releases are given in the Appendix.

Figure 3. Roza-Dam to McNary-Detection Smolt-to-Smolt Survival Index with respect to Julian Week grouping (Natural Smolt - Solid diamonds and sold lines, Hatchery Smolt - clear squares and dashed lines)

Figure 3. (continued) Roza-Dam to McNary-Detection Smolt-to-Smolt Survival Index with respect to Julian Week grouping (Natural Smolt - Solid diamonds and sold lines, Hatchery Smolt - clear squares and dashed lines)

# Appendix E1 <br> Annual Report: Comparisons between Smolt-Trait Measures of Hatchery x Hatchery- and Natural x Natural-Brood Stock for Brood-Years 2002-2017 Upper Yakima Spring Chinook 

Doug Neeley, Consultant to the Yakama Nation

## Summary

Hatchery x Hatchery (HxH or Hatchery Control - HC) and Natural x Natural (NxN or Supplemental Hatchery -SH) stock ${ }^{1}$ reared at the Cle Elum Facility were allocated to Clark Flat acclimation-site raceway pairs from brood year 2002 through the present. With the exception of the 2013 brood (released as smolt in 2015), the raceways within each pair were assigned different feed treatments. To avoid potential interaction with treatments that differed over years, the treatment that was common over all years was used in this analysis.

The following juvenile traits are analyzed:

1) Volitional-release-to-McNary survival
2) Percent of fish detected leaving pond (volitional release)
3) Mean and median McNary Dam (McNary) passage date
4) Mean and median acclimation-pond volitional-release date

Of these above enumerated traits, the HxH - NxN main effect differences that were significant at the $5 \%$ significance level were:
2) Percent of fish detected leaving the pond, the HxH cross having the lower percentage over years (and presumably having the lower pre-release survival);
3) McNary Mean and Median Passage Date, HxH cross having later mean and median passage dates over years.

[^21]
## Design of Experiment and Analysis Procedures

The HxH stock assignment was superimposed at only the Clark Flat Acclimation Site at which there were three pairs of raceways ${ }^{2}$ with two feed treatments ${ }^{3}$ allocated to the different raceways within each pair, the treatments not common to all years being excluded ${ }^{4}$ from the analysis in this report. The HxH Stock was allocated to one of the three pairs of raceways, and the NxN Stock to the other two pairs. Thus there were twice as many raceways at Clark Flat assigned to the NxN Stock than to the HxH Stock. The "error" in the analyses of variation presented in this report is primarily ${ }^{5}$ based on the variation among the NxN raceways within years.

A proportion of fish in each raceway was PIT-tagged for the primary purpose of estimating smolt-to-smolt survival from volitional release to McNary Dam on the Columbia River, located 70 km below the Yakima River confluence with the Columbia River. Beginning with the 2006 brood, there were twice as many HxH fish PIT-tagged per raceway than there were NxN fish to give approximately an equal total number of PIT-tagged fish for both the HxH and NxN stocks at Clark Flat.

Both the main effect $\mathrm{HxH}-\mathrm{NxN}$ difference and the annual $\mathrm{HxH}-\mathrm{NxN}$ differences' interaction with years were tested at the $5 \%$ significance level using either a weighted-least-squares analysis of variance or a weighted-logistic-analysis of variation ${ }^{6}$. The analyses of variation are presented in Appendix A. Year was taken to be a random effect; therefore, the weighted mean main-effect difference over years was tested against the $\mathrm{HxH}-\mathrm{NxN}$ interaction with years, and that interaction was tested against the "error" variation. Wilcoxon Paired Difference Signed Rank Test was also used to test for median $\mathrm{HxH}-\mathrm{NxN}$ differences over years.

[^22]
## Release-to-McNary Smolt-to-Smolt Survival

The mean Release-to-McNary survival is the estimated percent of all PIT-Tagged fish detected leaving the acclimation site that pass McNary. Estimates are given in Figure and Table 1. The main-effect-mean difference between stock was not significant at the $5 \%$ level (Type 1 Error $\mathrm{P}=$ 0.1212, Appendix Table A.1.). The HxH mean is higher ${ }^{7}$ than the NxN mean in $64 \%$ of the 14 years thus far analyzed. The Stock x Year interaction was significant at the 5\% significance level (Type 1 Error $\mathrm{P}=0.0108$, Appendix Table A.1) with highly variable HxH-NxN differences observable over years from Table 1.

[^23]
## Mean Percent of PIT-Tagged Smolt Detected leaving the Acclimation Site

Figure and Table 2. present the individual release-year HxH and NxN stock percentages of fish detected leaving the acclimation site. The estimate is simply the ratio as a percentage ${ }^{8}$ of the number of fish detected leaving the acclimation-site raceway to the total number of fish originally PIT-tagged; this percentage could be used as a measure of pre-release survival ${ }^{9}$. The HxH - NxN main-effect mean difference is negative and significant at the $0.05 \%$ level (Type 1 Error $\mathrm{P}=0.0014$, Appendix Table A.2.), indicating a lower pre-release HxH survival compared to that for the NxN stock The stock comparisons’ interactions with years was not quite significant at the $5 \%$ level (Type 1 Error $\mathrm{P}=0.0779$, Appendix Table A.2. The HxH mean is lower than the NxN mean in $85 \%$ of the 14 years thus far analyzed.

Figure 2. Release-Year 2004-2017 HxH and NxN Mean Percent of PIT-Tagged Smolt detected at Release from Clark Flat Acclimation Site

[^24]
## Mean McNary-Dam Juvenile-Passage Dates

The mean and median Dates of McNary Passage are respectively given in Figures 3.a. and 3.b. with associated Tables 3.a. and 3.b. Based on means, both the HxH - NxN main-effect difference and the $\mathrm{HxH}-\mathrm{NxN}$ comparisons' interaction with year were significant (Type 1 Error $P=0.0083$ and $P=0.0173$, respectively; Appendix Table A.3.). The Wilcoxon Ranked Sum test for median differences was also significant at the $5 \%$ level. Based on differences between the mean and median (Table 3.c.), there is little evidence of skewness in McNary passage date (mean of the mean - median HxH differences $=0.2$ ) and (mean of the mean - median NxN differences $=$ 0.0 ).

## Volitional Release Dates

The mean and median dates of detections of smolt leaving acclimation ponds are given in Figures 4.a. and 4.b. with the associated Tables 4.a. and 4.b. The negative mean $\mathrm{HxH}-\mathrm{NxN}$ main-effect difference in means was not significant at the $5 \%$ level (Type 1 Error $P=0.1295$, Appendix Table A.4) but the $\mathrm{HxH}-\mathrm{NxN}$ interaction with years was significant (Type 1 Error P $=0.020$ ). The less powerful non-parametric Wilcoxon Rank Sign Test for differences in medians was also not significant at the $5 \%$ level. Note from Table 4.b., that the three largest magnitudes by far among the median differences was associated with 2012, 2016, and 2017, and in all three cases it was the HxH stock that was leaving the acclimation site much earlier than the NxN stock. These years were the main contributor to the mean of the HxH -NxN median differences over years being -3.3; when these years are removed from the analysis, the mean of the $\mathrm{HxH}-\mathrm{NxN}$ median differences over years is near 0 .

Based on the mean - median difference in Table 4.c., there is some evidence of a right-skewed distribution over years for both the HxH (mean of the mean - median HxH differences = 3.4) and NxN stock (mean of the mean - median NxN differences = 2.2); however, based on the ranked values used in the Wilcoxon Rank Sign Test, the HxH - NxN median differences have not attained a significance level of $5 \%$.

Appendix E2<br>2017 Comparison of Hatchery and Natural Origin Brood Stock of Spring Chinook Release-to-Roza-Dam Smolt-to-Adult Survival<br>\section*{Introduction}

Beginning in Brood-Year 2002, one pair of raceways at the Clark Flat acclimation site was assigned to progeny derived from Upper-Yakima Spring Chinook hatchery-brood crosses (HxH) for the purpose of assessing the longterm effect of using the hatchery-brood progeny of each generation to serve as the brood-stock for the subsequent generation. All other raceways (including all those located at the Jack Creek and Easton acclimation sites) used crosses from naturally spawned parents ( NxN ). No HxH hatchery-produced returns are allowed to spawn in the wild.

The variables analyzed included in this report are:
a) Smolt-to-adult survival from smolt release at Clark Flat to adult return at Roza Dam (Roza); and
b) Age-3 percent of Roza returns from Clark Flat.

## Summary

While there was neither a significant nor substantial difference between the over-year mean HxH and NxN smolt-tosmolt survival from acclimation-pond release to McNary Dam passage, the HxH Clark Flat acclimation-site release smolt-to-adult survival to Roza Dam adult return of $0.46 \%$ was highly significantly greater than the $0.41 \%$ of the NxN release (Type 1 Error $\mathrm{P}=0.0001$, two-sided test). There is no direct measure of interaction of the HxH - NxN smolt-to-adult survival differences with years; but in 4 of the 12 brood years the NxN stock survival estimates exceeded those of the HxH stock, and of those 4 years, 3 were the first brood years. The NxN and HxH percentages of age-3 adults barely differed ( $31.8 \%$ for the HxH stock and $30.4 \%$ for the NxN stock Type 1 Error P=0.39, twosided test).

## Assignment of Clark Flat Adult Recoveries to Stock, Acclimation Site, and Brood Year

Two of the Clark Flat acclimation site-raceways were assigned to HxH-brood juveniles, the other four raceways were assigned to NxN -brood juveniles. All smolt were coded-wire tagged (CWT), the NxN juveniles being tagged in the snout and HxH juveniles being tagged behind the dorsal fin.

1. Adults PIT-tagged as Smolt before Release: In brood years 2002-2007 approximately $5 \%$ of the smolt within each raceway were tagged with a Passive Integrated Transponders (PIT-tag), resulting in the NxN smolt having twice as many PIT-tagged smolt as the HxH smolt. Beginning in BY-2007, the percentage of the raceways assigned to the HxH stock was increased to approximately $10 \%$ in order to equate the total numbers of PIT-tagged smolt of the HxH to that of the NxN stock. Adult PIT-tag returns could be directly assigned to stock, to the Clark Flat acclimation site, and to brood-year.
2. Non-PIT-Tagged Adults Aged at Returns: All non-PIT-tagged smolt were elastomer-tagged with a unique color for each of the three acclimation site; therefore the Clark Flat released returns could be identified and then assigned to the NxN and HxH stock based on the CWT's body location.
2.a. Non-PIT-tagged Scale-Aged Returns: On return, scales were taken from sampled adults and sent to be scale-aged. Those scale-aged returns could then be assigned to brood year.
2.b. Non-PIT-tagged Fork-Length-Assigned Returns: For return years 2005 through 2016, principle component analyses were performed on standardized ${ }^{1}$ fork length, post-orbital hypural length ( POH ), and fish weight differences for return years 2005 through 2016 using all PIT-tagged-aged and scale-age Roza Dam returns to distinguish between Age-3 and greater than Age-3 age fish. In all but one of those years, fork length was the major contributor to the principle component index. In six of those years, fork length was the only contributor, and fish weight was never included. Based on this and for consistency over years, the decision was made to use fork-length as the basis for assigning non-aged returns to Age-3 and greater-than-Age-3 categories for those and subsequent years. The principle component coefficients leading to the decision to use fork length are given in Appendix A (Table A.1.).

Using all PIT-tagged and scale-aged returns within each brood year irrespective of acclimation site, the reverse cumulative fork-length distribution of the Age-3 and the cumulative fork-length distribution of greater-than-Age3 smolt were approximated using t-distributions based on the respective age's return-year mean and standard deviation. The point at which these cumulative distributions crossed was used as the discriminate value to assign returns to the Age-3 and greater than Age-3 categories. Within each brood year, the fork-length-based discriminant was then applied to the Clark Flat scale-aged returns to determine its accuracy. Of the total of 2,287 scale-aged returns over all brood years, the fork-length discriminant values correctly assigned $98.2 \%$ of the scale-aged returns to the correct age groups ( $98.8 \%$ correct for Age-3 returns and $98.0 \%$ correct for greater-than-Age-3 returns, indicating little bias). The return-year fork-length values used to assign non-aged adults to Age-3 and greater-than-Age-3 classes is also given in Appendix A (Table A.2.).

The Age-5 and Age-4 returns are not separated because in several years there were no Age-5 PIT-tagged or Scale-Aged returns, but since there were more non-aged returns subjected to the fork-length assignment, there still could have been Age-5 returns in that category. Over all brood years, of the greater-than-Age-3 scale-aged returns, only $2.3 \%$ were Age-5 adults, and of the greater-than-Age-3 PIT-tagged returns, only $2.1 \%$ were Age-5 adults; therefore the bias of the pooling Age-4 and Age-5 return data over brood years will be negligible.

The within-brood-year-assigned return tallies were separately pooled separately for the NxN and HxH stock over the categories given above (1., 2.a., and 2.b.), and these pooled tallies were then divided by their respective Clark Flat release numbers as estimates of the NxN and HxH survivals ${ }^{2}$.

## Survival Comparisons between the Hatchery and Natural Crosses

Table and Figure 1. present HxH and NxN adult return survival to Roza of CWT and PIT-tagged hatchery smolt ${ }^{3}$ released from the Clark Flat acclimation site. The final brood-year estimates do not distinguish between Age-4 and Age-5 returns. The HxH stock's mean survival to Roza when pooled over age groups was significantly higher than that for the NxN stock's $(0.455 \%-0.407 \%=0.048 \%$, estimated Type 1 Error $\mathrm{P}=0.0001$, Appendix Table B.1.). Note that brood-year 2006's high survival and the high $\mathrm{HxH}-\mathrm{NxN}$ survival difference had a large effect on the

[^25]${ }^{3}$ This represents the pooling of PIT-tagged, scale-aged, and fork-length assigned returns to age groups.
pooled means and their difference ( $1.42 \%-1.12 \%=0.30 \%$ ); even so, the pooled $\mathrm{HxH}-\mathrm{NxN}$ difference with broodyear 2006 omitted was still highly significant (Type 1 Error $\mathrm{P}=0.0043$ ).

There is possible source of bias: A higher rate of CWT shedding for snout-tagged fish would result in a lower estimated NxN survival giving a smaller $\mathrm{NxN}-\mathrm{HxH}$ survival difference.

There is inconsistency in survival indices among the PIT-tagged, scaled-aged, fork-length assigned groups. This is discussed in Appendix C. wherein another survival measure is discussed.

Figure 1. Cle Elum Smolt-Release to Roza Dam Adult-Return Survival of Upper Yakima Spring Chinook Naturally ( $\mathbf{N x N}$ ) and Hatchery (HxH) Reared Broodstock for Brood Years (BY) 2002-2013

## Age-3 Percentage Comparisons between the Hatchery and Natural Crosses

The HxH and NxN Age-3 percentages and their differences are given in Table and Figure 2. The HxH stock's mean Age-3 percentage differed only slightly and non-significantly from that of the NxN stock when pooled over years (31.8\% - 30.4\% = 1.4\%, estimated Type 1 Error P = 0.39, Appendix Table B.2.

## Appendix C. Evaluation of Survival for the Three Age-Classified Adult Returns (PIT-Tagged, Scale-Age, and Fork-Length based Assignments)

There are separate estimates of the number of total smolt released and the number of PIT-tagged smolt released. The former is based on number placed in the raceways minus the mortalities in the rearing and acclimation site raceways prior to release; the latter is based on the number of PIT-tagged smolt detected leaving the acclimation site. The former minus the latter is taken to be the number of non-PIT-tagged smolt released which, on return, is comprised of scale-aged and fork-length-assigned recoveries. It is not possible to obtain separate release-to-return estimates of the scale-aged and fork-length-assigned fish. However, it is possible to compute the yearly $\mathrm{HxH} / \mathrm{NxN}$ recovery ratios and the $\mathrm{HxH} / \mathrm{NxN}$ release ratios. If the estimated recovery ratio is greater than the release ratio, the estimated survival of the HxH stock is greater than that of the NxN stock; conversely, if the estimated recovery ratio is less than the release ratio, the estimated survival of the NxN stock is greater than that of the HxH stock. Dividing yearly the recovery ratio by the yearly release ratio gives a relative survival index,

$$
\text { Survival Index }=(\mathrm{HxH} / \mathrm{NxN} \text { recovery ratio }) /(\mathrm{HxH} / \mathrm{NxN} \text { release ratio }) .
$$

If the measure is greater than 1 , the HxH stock has the higher estimated survival, and if less than $1, \mathrm{NxN}$ stock has the higher estimated survival.

For the PIT-tagged-aged returns, the release-number base used is the number of PIT-tagged smolt detected at release. In the cases of the scale-age, fork-length, and their combined non-PIT-tagged assigned smolt, the release-number base used in the number of non-PIT-tagged released smolt. For all assigned returns, the release-number base is the total smolt released. For each grouping, the individual-year index measure is computed, the indices are then averaged over years, and the average index is statistically compared to 1 . The statistical summary given in Table C. 1 is for the mean $\mathrm{HxH} / \mathrm{NxN}$ Survival indices. Also presented in that table are the $\mathrm{HxH} / \mathrm{NxN}$ ratios of actual pooled survival estimates.

Table C.1. Evaluation of the various Age-Classification Measures

|  | Ratio of HxH/NxN recovery* to HxH/NxN release** |  |  |  | Ratio of pooled HxH and NxN survival estimates |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Grouping | Mean*** <br> Ratio Index | Standard Error | t-ratio | Type 1 Error p**** | Actual Survival Ratio HxH/NxN***** | $\begin{aligned} & \text { Type } 1 \\ & \text { Error } \\ & \mathbf{P}^{* * * * * *} \end{aligned}$ |
| PIT-tagged | 1.038 | 0.271 | 0.140 | 0.8911 | 1.082 | 0.8901 |
| Scale Aged | 3.713 | 1.029 | 2.636 | 0.0232 | n.a. |  |
| Fork Length | 0.739 | 0.319 | -0.820 | 0.4298 | n.a. |  |
| non_PIT | 1.080 | 0.206 | 0.391 | 0.7032 | 1.118 | 0.0001 |
| All-Aged | 1.075 | 0.193 | 0.386 | 0.7066 | 1.118 | 0.0001 |

* Number of HxH recovered divided by number of NxN recovered for each year
** Number of HxH released divided by number of NxN released for each year
*** Mean of Yearly Indices
$* * * *$ Tested against hypothesis that Ratio =1, degrees of freedom (DF) = 11
***** (Pooled HH Recovery/Pooled HH Release)/(Pooled NN Recovery/Pooled NN Release)
****** Tested against hypothesis that population HxH - NxN survival differences = 0, DF=11

The All-Aged Mean Ratio Index of 1.075 (bottom row of table) is not significant in this analysis (Type 1 Error $P=0.7066$ ); whereas the Actual Survival Ratio is highly significant (Type 1 Error $P=0.0001$ ) based on the analysis in the main text. Since the estimates in the main text are based actual survival estimates, and since the analysis used in the text takes into account the actual underlying distribution of survival-probability estimates (binomial distribution),
the assessment in the main text is taken to be the most appropriate. We note that the three ${ }^{4}$ actual $\mathrm{HxH} / \mathrm{NxN}$ survival ratios in the above table, which are based on pooled recovery and pooled release numbers over all years, all exceed the index value and all exceed 1; all of the three corresponding mean ratio measure indices also exceed 1 , indicating higher HxH survival as compared to the NxN survival.

The major purpose of the above table is to demonstrate a bias associated with the sampling of the returns that were scale-aged (and a corresponding bias associated with Fork-Length assessed returns). The Mean Ratio Index for scaleaged returns is 3.71 , suggesting that the survival of the HxH adults is approaching four times that of the NxN adults; whereas the Mean Ratio Index for the fork-length assigned smolt is 0.74 , suggesting that the survival of the HxH adults is about three-quarters of that of the NxN adults. The implication is that an individual HxH return had a higher chance of being sampled for scale-age assessment than an individual NxN return.

The possible bias impact is on the age distributions, the Age 3 percentage being independently estimated based on returns from the three age-assignment groups (Table C.2.)

Table C.2. Age-3 Percentage of Returns

| Age-Base | HxH | NxN | Difference | Error P |
| ---: | :---: | :---: | :---: | :---: |
| PIT-Tagged | $37.5 \%$ | $\mathbf{2 8 . 3 \%}$ | $9.2 \%$ | 0.0242 |
| Scale Aged | $23.4 \%$ | $\mathbf{2 4 . 9 \%}$ | $-1.5 \%$ | 0.1519 |
| Fork Length Aged | $34.9 \%$ | $31.1 \%$ | $3.8 \%$ | 0.0243 |
| Combined | $31.8 \%$ | $30.4 \%$ | $1.4 \%$ | 0.3902 |

As can be seen, the HxH-stock Age-3 percentages are significantly greater-than those of NxN stock for both the PITtagged and Fork-Length Aged returns, but not significantly different for the Scale-Aged returns. Note also that the Scale-Age returns have smaller estimated Age-3 percent returns than the other two age-assessment groups for both the HxH and NxN stock. When combined over all returns, there is little difference in the Age- 3 percentages between the two stocks.

Since the survival estimates are based on pooling all recoveries from all broods and releases, any bias due to broodyear assignment on the survival estimates is likely to be minimal.

# Appendix F <br> Annual Report: Comparison of Pro-Feed and BioVita Feed <br> Treatments evaluated on Natural-Origin Hatchery-Reared Upper- <br> Yakima Spring Chinook Smolt released in 2016 and 2017 

Doug Neeley, Consultant to Yakama Nation
Introduction

Within the pairs of raceways at Cle Elum, one raceway from each nine pairs of Raceway was allocated BioVita feed as a control treatment and the other was allocated PRO feed as a test treatment in brood years 2014 through 2016 broods. In this report, analyses are presented for the 2016 and 2017 releases from three acclimation sites ${ }^{1}$ of the first two broods for following juvenile characteristics:

1) Mean smolt-to-smolt survival from volitional release to McNary;
2) Mean proportion of PIT-tagged fish detected leaving the acclimation ponds;
3) Mean and median volitional release (acclimation pond outfall detection) date; and
4) Mean and median McNary Dam (McNary) smolt-passage date.

The current method of estimating detection efficiencies are discussed in a report entitled Methods of Estimating Smolt Survival and Passage.

## Smolt-to-Smolt Survival to McNary Dam

Table 1. presents the volitional release to McNary Dam smolt-to-smolt survivals of Pro and Bio-Vita fed smolt. There was neither a substantial nor significant difference in the main-effect smolt-to-smolt

[^27]survival means of Pro and BioVita feed treatments over years ( $P=0.76$, Appendix Table A.1.), and there were no substantial or significant treatment interactions with year or sites (associated F-ratios less than 1, Appendix Table A.1.).

Table 1. Brood-Year 2014 and 2015 Mean Release-to-McNary Smolt-to-Smolt Survival for Spring Chinook Smolt from Clark Flat, Easton and Jack Creek Acclimation Sites given Pro and BioVita (Control feed)

|  | Release Year |  |  |  |  |  |  |  |  | Pooled |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| BioVita | Released | 3,838 | 5,646 | 5,744 | 15,228 | 3,853 | 5,553 | 5,841 | 15,247 | 30,475 |
| Tested - Control Survival |  | -1.8\% | -0.8\% | 0.7\% | -0.5\% | 2.6\% | 0.3\% | -7.3\% | -2.0\% | -1.2\% |

## Percent of PIT-tagged Fish Detected Leaving Acclimation Ponds

The percent of PIT-tagged smolt detected leaving the acclimation site may give an indication of prerelease survival (time-of-tagging to release-detection survival).

Table 2. presents Pro- and BioVita- fed percent of PIT-tagged smolt detected leaving the acclimation ponds. As with smolt survival, there was neither a substantial nor significant difference in the percentages leaving the ponds over years ( $P=0.38$ Appendix Table A.2.), and there were no substantial or significant treatment interactions with year or sites (associated F-ratios less than 1, Appendix Table A.2.).

Table 2. Brood-Year 2014 and 2015 Percent of Spring Chinook Smolt leaving Acclimation Sites for Spring Chinook Smolt from Clark Flat, Easton and Jack Creek Acclimation Sites given Pro and BioVita (Control feed)

|  | Release Year |  |  |  |  |  |  |  |  | Pool |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| Tested - Control Percent |  | -0.6\% | 0.8\% | 0.6\% | 0.4\% | 1.5\% | -0.7\% | -0.9\% | -0.2\% | 0.1\% |

## Volitional Release Dates and McNary Passage Dates

There are no significant main-effect differences between the Pro and BIOVITA mean or median release dates or between the fed releases. However, there were significant interactions of the differences with the release years (Appendix Tables A.3.a. through A.3.d.). The nature of the interactions can be seen in Table 3. In 2016, Pro Treatment mean and median dates are later than the BioVita release and McNary passage dates, but in 2017 all the respective Pro dates are earlier; although the differences are much smaller for the McNary passage dates than for the release dates. (Respective tables of means inclusive of acclimation site means are given in Appendix Tables A.4.a. through A.4.d.).

Table 3. Brood-Year 2014 and 2015 Mean and Median Dates of Volitional Release McNary Passage

|  |  | Mean Date of <br> Volitional Release |  | Median Date of <br> Volitional Release | Mean Date of <br> McNary Passage | Median Date of <br> McNary Passage |  |  |  |

# Appendix G <br> Annual Report: 2008-2017 Fall and 2009-2017 Summer Chinook Smolt-to-Smolt Survival to McNary Dam of Releases into the Yakima Basin 

Doug Neeley, Consultant to Yakama Nation

## Introduction

Errors in the estimation of Release-to-McNary Dam survival were discovered; therefore Fall and Summer Chinook 2008-2016 survival-index estimates (survival) from time-of-tagging-to-McNary detection were re-estimated and re-analyzed. It is noted that the conclusions concerning survival given in this report are not in conflict with those presented in the previous 2016 report.

## Summary

In 2015, 2016, and 2017, Fall Chinook releases from Prosser, Wanawish Dam, and the mouth of the Yakima were made on various dates. There is sufficient evidence from these years and from previous years when late Fall Chinook releases were made that releases made in late May or later are usually subject to lower and often much lower survivals ${ }^{1}$ than releases made earlier. While the survival of releases made in 2017 run counter to this observation, survival from previous years suggest that late releases should generally be avoided. Releases of Summer Chinook generally support this conclusion. Further, there is evidence that standard early ${ }^{2}$ releases of Fall Chinook made from 2015 through 2017 have experienced a drop in release-to-McNary survival (range: $6.9 \%$ to $22.8 \%$ ) when compared to the standard early releases made from 2008 through 2014(range: 23.6\% to 39.3\%).

## Subyearling Fall Chinook Smolt-to-Smolt Survival

In 2015, poor in-river Yakima and Columbia River conditions existed when the standard early release were made from Prosser, and the decision was made to make later releases at that site and additional sites downstream of Prosser (below Wanawish Dam a short distance up-stream of the Mouth of the

[^28]Yakima River and into the Mouth) to determine whether survival would improve with a decrease in the distance and presumably in the travel time to McNary Dam. Releases were also made from these three sites in 2016 and 2017, these sites being referred to as the common release sites

2015 Releases: All Yakima stock 2015 survivals were abysmally low except for the May $29^{\text {th }}$ release into the mouth of the Yakima (Table 1.a. and Figure 1.). The May $29^{\text {th }}$ release into the mouth of the Yakima had a much higher survival ( $40.0 \%$ ) than other late releases; however, four days later (June $2^{\text {nd }}$ ), another release was made into the mouth of the Yakima, and its survival to McNary was only 8.7\%, suggesting that the conditions in the mouth of the Yakima and in the Columbia River had rapidly deteriorated over a short period of time. Note from Table 1.a. that, for some reason, the 2015 earlyMay Prosser release of the Yakima stock (Table 1.a.) had a much shorter travel time from Prosser to McNary (11 days) than the early-June release (33 days). In addition to the early releases of the Yakima stock from Prosser, there was an early release from Prosser of the Priest Rapids stock. The survival to McNary of the Yakima and the Priest Rapids stock were nearly equal and extremely low [6.9\% for Yakima stock (Table 1.a.) and 6.7\% for Priest Rapids Stock (Table 1.b.)].

2016 Releases: Referring to Table 2.a. and Figure 2., the 2016 survival to McNary of the earlier releases were the highest by far for all three common release sites, but subsequent Prosser releases in late May and late June again had abysmal survivals as did late June releases at Wanawish (Table 2.a.). The late release into the Mouth was comparable to the early releases at Prosser and Wanawish. There was an additional single release at Benton City in early June; none were detected at McNary (Table 2.b.).

2017 Releases: Referring to the Prosser releases(Table 3. and Figure 3.), there was little difference in the late May and early June survivals ( $26.3 \%$ and $27.8 \%$, respectively); however, the early release at Prosser was more than $5 \%$ less than the late May release ( $20.7 \%$ and $26.3 \%$ respectively). Note that the early-May-release travel time to McNary from Prosser was 35 days compared to the 15 and 16 day travel times for late- May and Early-June releases, suggesting that the early released smolt were taking more time in their downstream migration and may have been subjected to a higher in-stream mortality before reaching McNary resulting in the lower early-release survival. The 2017 release suggest that there may occasionally be conditions where later releases are warranted.

Table 1.a. 2015 Yakima Stock Release-to-McNary Fall Chinook Survival-Index Estimates from three common Release Sites

| Release Site | Release Date > | Early May | Late May | Early June |

| Mouth | Survival |  | 2,023 | 2,026 |
| Mouth | Survival |  | 17 | 15 |

Red Texted survivals the highest within release site within year
Note the large Travel Time of first (5-May) releases compared to later releases

There is little information on late releases prior to 2016, but there were a couple of years for which there is some information. In 2008 there were a pair of late April releases and a pair of late May releases of Little White stock, and the pooled survival to McNary of the two lateApril releases was $6 \%$ higher $^{3}$ than that of the late-May releases (Table 4.a.). In 2012, there was a slightly higher (3\%) survival for the Yakima stock late-April release than for an earlyMay release (Table 4.b). The other previous releases were made in April and Early May for which there were no comparable later releases.

Table 4.a. 2008 Yakima Stock Release-to-McNary Fall Chinook Survival-Index Estimates

|  |  |  |  |  |  | Late April |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Release Site May |  |  |  |  |  |  |  |
|  | Release Date | $04 / 25 / 08$ | $04 / 29 / 08$ | Pooled | $05 / 22 / 08$ | $05 / 27 / 08$ | Pooled |
| Prosser | Survival | $35.5 \%$ | $36.4 \%$ | $36.0 \%$ | $32.8 \%$ | $27.3 \%$ | $30.0 \%$ |
|  | Number Tagged | 5000 | 5001 | 10001 | 5001 | 5005 | 10006 |

Note: In this report, pooled estimates are the total recoveries over the releases divided by the total smolt tagged over releases. The multi-day early releases presented in Tables 1.a. and 1.b. are also pooled releases.

Table 4.b. 2012 Yakima Stock Release-to-McNary Fall Chinook Survival-Index Estimates

| Release Site | Release Date | $04 / 27 / 12$ | $05 / 12 / 12$ |
| :---: | :---: | :---: | :---: |
| Prosser | Survival | $30.5 \%$ | $27.5 \%$ |
|  | Number Tagged | 9264 | 10370 |

Table 5.a. and Figure 5. present pooled April and Early May survival estimates for years 2008 through 2017. Also presented are the pooled estimated survivals over 2008 through 2014 and the pooled

[^29]estimates over 2015 and 2017 along with the minimum survival within the 2008 through the 2014 grouping and the maximum survival within the 2015 through 2017 grouping. All 2015 through 2017 early release survival estimates are less than all 2008 through 2014 early release survival estimates. A logistic analysis of variation between the yearly grouping survivals against the within yearly grouping survivals is given in Table 5.b. A one sided test for the pooled 2015-2017 survival being less than the 2008-2014 survival is significant at the $5 \%$ level (Type 1 Error p $=0.0389$, 1 -sided test). The reason for the pooling of the 2015 through 2017 releases is that these were the years when the common release sites of Prosser, Wanawish, and the Yakima Mouth sites were used, triggered by the extremely low early-release survival in 2015.

*** Test for 2015-2017 Survival being less than the 2008-2014 Survival against the hypothesis of no difference

## Summer Chinook Smolt-to-Smolt Survival

Table 6. gives McNary survival for all releases made into the Yakima basin. As was the case for Fall Chinook releases, 2015 Summer Chinook releases experienced abysmal survivals. With the exception of the single year release below Roza Dam (2013), all late releases of Summer Chinook for all years had survivals less than $5 \%$. This supports the conclusion that releases made after mid-May should generally be avoided.

# Appendix H <br> Annual Report: 2017 Coho Smolt-to-Smolt Survival of Releases into the Yakima Basin 

Doug Neeley, Consultant to Yakama Nation

## Introduction

In 2017 only Yakima stock smolt releases were made into the Yakima basin. The release sites were from Holmes and Stiles ponds, from Prosser hatchery, and from Ahtanum Creek smolt ${ }^{1}$ plants on the La Salle High School grounds. This report presents smolt-to-smolt survival estimates of early releases from release site to McNary Dam for all 1999 through 2017 early releases of Yakima Stock Spring Chinook.

## Summary

In 2015 there was an extremely low snow pack and an early snowmelt. In-stream conditions resulted in poor smolt-to-smolt survivals. Survivals were also poor in 2016 compared to pre-2015 releases. In stream conditions were much better2017 and the survival rates were comparable to those prior to 2015.

## 1999 through 2017 Smolt-to-Smolt survival of early Yakima Stock Releases

Table 1 presents the survivals of early ${ }^{2}$ released Yakima-stock ${ }^{3}$ Coho smolt from all sites from 1999 through 2017. Table 1 also presents the release dates and the estimated mean McNary passage dates and their associated mean travel time in days. Note that the early release date varies greatly over years ${ }^{4}$.

* 1999 through 2002 early releases were early May or mid-May releases. Subsequent year releases were in March or April.
** No Yakima Stock released in 2000
*** Ahtanum releases made before 2016 were Parr releases and not Smolt releases
Yellow-Shaded Cells: $\mathbf{2 0 0 3}$ releases from Holmes and Easton were both reared at Prosser and not PIT-coded as to release source and are given as the same values
Blue-Shaded Cells: Survivals of less than $10 \%$
Focusing on the three sites with 2015 releases (Stiles, Lost Creek, and Prosser): For Stiles the 2015 and 2016 McNary survivals were respectively the lowest and $3^{\text {rd }}$ lowest survivals of its 15 release years; for Lost Creek the 2015 survival was $2^{\text {nd }}$ lowest and the 2016 survival was $3^{\text {rd }}$ lowest of its 14 release years; and for Prosser the 2016 survival was lowest and the 2015 survival was $2^{\text {nd }}$ lowest of its 11 release years.

Of those sites, releases were also made from Stiles and Prosser made in 2017. The 2017 Stiles survival to McNary of $35.8 \%$ was slightly greater than the pooled pre-2015 survival estimate of $34.7 \%$. The 2017 Prosser survival to McNary of $82.1 \%$ was second highest survival over all release year survivals. The survival estimates for Stiles, Lost Creek, and Prosser are also presented in Figures 1 through 3.

Figure 1. Survival to McNary from Stiles Release Site

Figure 2. Survival to McNary from Lost Creek Release Site

Figure 3. Survival to McNary from Prosser Release Site

More formal analyses were conducted on the survival analyses for these three sites. The analyses, based on logistic analyses of variance, were comparisons of the pooled 2015-2016 survivals to the
pooled pre-2015 survivals and the comparisons of 2017 survivals to the pooled pre-2015 survivals, the pooled estimates ${ }^{5}$ being given in Table 1.

For Stiles, the difference between the pooled 2015-2016 survival of $18.1 \%$ was significantly less than the pre-2015 survival of $34.7 \%$ (Type 1 error P = 0.0276, Appendix Table A.1.a), but the 2017 survival of $35.8 \%$ differed by only $1.1 \%$ which from the pre-2015 survival was far from a significant (Type 1 error $\mathrm{P}=0.8772$, Appendix Table A.1.b).

For Lost Creek, the difference between the pooled 2015-2016 survival of $4.5 \%$ was significantly and substantially less than the pre-2015 survival of $22.3 \%$ (Type 1 error $P=0.0271$, Appendix Table A.2). There was no release from Lost Creek in 2017.

For Prosser, pooled 2015-2016 survival was much less than pre-2015 releases (respective survivals $27.7 \%$ and $56.5 \%$ ) but not significantly so because of the high among year variation within the two groupings (Type 1 error P = 0.1437, Appendix Table A.3.a). Conversely, the 2017 survival of $82.1 \%$ was much larger than the pre-2015 survival but again not significantly so (Type 1 error P = 0.2413, Appendix Table A.3.b).

There was a single Easton release after 2014, the 2016 release, and its survival of $13.3 \%$ was less than the pooled pre-2015 survival of $18.3 \%$ but not significantly so (Type 1 Error $P=0.5543$, Appendix Table A.4). The individual year survivals are plotted in Figure 4.

Releases were made in 2016 and 2017 from Holmes. The 2016 survival of $19.2 \%$ and the 2017 survival of $19.4 \%$ were substantially and significantly greater than the pooled pre-2015 survival of $8.0 \%$ (Type 1 Error $\mathrm{P}=0.0201$, Appendix Table A.5). Note from Figure 5 that the pre-2015 survivals from Holmes were uniformly low and all were less than both the 2016 and 2017 releases' survivals.

There was a single pre-2015 release from Buckskin Slough made in 2014 and a 2016 release, with respective survivals of $50.0 \%$ and $20.4 \%$, therefore there is no among year variation within the pre-2015 period and the 2015-2016 period that serves as appropriate basis of the comparison (used in the analyses of the other site comparisons). A less appropriate binomial test was made to compare these two survivals yielding a Type 1 error $P$ estimate much less than 0.0001 , indicating a decrease in survival from 2014 to 2016.

There were smolt releases at Ahtanum in 2016 and a 2017 with respective survivals of $18.8 \%$ and $39.6 \%$. A binomial test was also made to compare these two survivals again yielding a Type 1 error P estimate much less than 0.0001 , indicating an increase in 2017 survival over the 2015 survival.

With the exception of releases made from Holmes, the general conclusion from this analysis is that the 2015-2016 survivals were less than those in previous years but that the 2017 survival had returned to pre-2013 levels.

[^31]Figure 4. Survival to McNary from Easton Release Site

[^0]:    1. The mean jack proportion of spawning escapement from 1999-2017 was 0.09.
[^1]:    ${ }^{1}$ Including minor tributaries.

[^2]:    ${ }^{1}$ Carcasses sampled in 1997 had a mix of MEHP and POHP lengths taken. Only POHP samples are given here.
    ${ }^{2}$ Mean of mean values for 1996-2016 post-eye to hypural plate lengths.
    Appendix B. Yakima River / CESRF Spring Chinook Salmon - Yakama Nation Data Summary
    2017 Annual Report, May 31, 2018

[^3]:    ${ }^{1}$ Including minor tributaries.

[^4]:    a. Includes 1752 fish tagged and released in late August and early Sept.

[^5]:    ${ }^{\text {A }}$ Estimated population of tagged study fish alive to MCN tailrace (included fish detected at the dam and those estimated to pass undetected). CJS estimation of S1 uses PIT-tags detected on bird colonies in the Columbia River estuary and adult detections to augment the NOAA Trawl detections below BON
    ${ }^{\text {B }}$ Incomplete. 2 -salt returns through June 24. 2017.

[^6]:    ${ }^{1}$ BIO = BioVita (BioOregon Protein Inc.) or control diet; EWS = EWOS (EWOS Canada Ltd.). All fish were switched to BioVita diet beginning May 3, 2007. All fish are progeny of wild/natural parents unless denoted as HH which designates the hatchery control line. "Avg BKD" denotes the average BKD ELISA ranking of the female parents whose progeny were in these ponds.
    ${ }^{2}$ The number of fish released is estimated as the total number of fish counted at marking less mortalities documented from mark to release.

[^7]:    ${ }^{1}$ BIO $=$ BioVita (BioOregon Protein Inc.) or control diet; STF = salt-water transition diet at acclimation sites. All fish are progeny of wild/natural parents unless denoted as HH which designates the hatchery control line beginning with brood year 2002. "Avg BKD" denotes the average BKD ELISA ranking of the female parents whose progeny were in these ponds.
    ${ }^{2}$ The number of fish released is estimated as the total number of fish counted at marking less mortalities documented from mark to release.

[^8]:    BIO $=$ BioVita (BioOregon Protein Inc.) or control diet; STF = salt-water transition diet at acclimation sites. All fish are progeny of wild/natural parents unless denoted as HH which designates the hatchery control line beginning with brood year 2002. "Avg BKD" denotes the average BKD ELISA ranking of the female parents whose progeny were in these ponds
    ${ }^{2}$ The number of fish released is estimated as the total number of fish counted at marking less mortalities documented from mark to release.

[^9]:    ${ }^{1}$ BIO = BioVita (BioOregon Protein Inc.) or control diet; STF = salt-water transition diet at acclimation sites. All fish are progeny of wild/natural parents unless denoted as HC which designates the hatchery control line beginning with brood year 2002. "Avg BKD" denotes the average BKD ELISA ranking of the female parents whose progeny were in these ponds.
    ${ }^{2}$ The number of fish released is estimated as the total number of fish counted at marking less mortalities documented from mark to release.

[^10]:    ${ }^{1}$ All fish are progeny of wild/natural parents unless denoted as HC which designates the hatchery control line beginning with brood year 2002. "Avg BKD" denotes the average BKD ELISA ranking of the female parents whose progeny were in these ponds. PRO=BioPro diet, VIT=BioVita diet, Bio-Oregon products.
    ${ }^{2}$ The number of fish released is estimated as the total number of fish counted at marking less mortalities documented from mark to release.

[^11]:    ${ }^{1}$ The data reported here are considered the best available as of the deadline for this report. However, analyses of the data and relationships presented here are still ongoing and a final report with updates to passage and stock-proportion estimates will be included in next year's annual report.
    ${ }^{2}$ As of this writing the 2017 estimates of these stock-proportion estimates are not available.
    ${ }^{3}$ Wild refers to in-stream-spawned smolt whether their parents are spawned in the wild or spawned or reared in the hatchery. All hatchery returns that escaped to spawn would have had parents that were of natural origin.

[^12]:    ${ }^{4}$ In order of downstream detection: McNary, John Day, and Bonneville Dams.

[^13]:    ${ }^{5}$ This method was actually performed for all brood-year tallies. The elastomer-tag basis was selected over the PIT-tad basis based on correlating juvenile-passage estimates with returns. The elastomer-based estimates for all other years of passage were used except for 2016 when the estimates were clearly biased.

[^14]:    ${ }^{6}$ This measure is taken as an surrogate of spawner number

[^15]:    ${ }^{7}$ The sample rates are given for each timer-gate setting in Appendix Table A.

[^16]:    ${ }^{8}$ Expanded passage estimate $=($ Calibrated passage estime $) *($ calibration Index)
    ${ }^{9}$ Timer Gate Rate is proportion of time that the bypass gate is opened to Sample Room

[^17]:    ${ }^{10}$ Provided by the Washington Department of Fish and Wildlife's Molecular Genetics Lab

[^18]:    ${ }^{1}$ The first outmigration year of Upper Yakima River hatchery-origin Spring Chinook
    ${ }^{2}$ Pooled survival over years is the total of McNary passage estimates over years divided by the total released over years.
    ${ }^{3}$ Estimation procedures for survival are illustrated in the 2017 report Methods of Estimating Smolt Survival and Passage.

[^19]:    ${ }^{4}$ Before expansion by McNary detection efficiencies.
    ${ }^{5}$ The $\mathbf{7 8 \%} \%$ is significantly greater than what would be expected by chance $(\mathbf{P}=\mathbf{0 . 0 1 5 4})$ based on a 1 -sided binomial distribution.

[^20]:    ${ }_{7}^{6}$ Passing Roza contemporaneously with hatchery smolt
    ${ }^{7}$ The $67 \%$ is not significantly different than what would be expected by chance $(P=0.3018)$ based on a 2 -sided binomial distribution sign test).

[^21]:    1 HxH and NxN Stock are part of a domestication selection study. The original progenitors of both stocks were wild Upper-Yakima Stock. Both Stocks are reared in the hatchery, but HxH are progeny of hatchery-spawned parents, and NxN are progeny of naturally spawned parents. Protocol dictates that HxH progeny never spawn outside of the hatchery, and NxN progeny are never spawned in the Hatchery.

[^22]:    ${ }^{2}$ Raceways within each pair were similar in that they were physically adjacent to each other and in that they both received progeny from the same sets of diallele crosses, there being different male and female parental sets assigned to the different raceway pairs. This could result in smolt within raceway pairs being more similar than smolt from different raceway pairs due to genetic and/or parentaleffect similarities within pairs.
    ${ }^{3}$ In every year, two treatments were evaluated. For 2004 through 2006 releases, they were Low and High Nutrition BioVita Feed levels Feeds, the High BioVita Feed level being the standard or Control over all years that the HxH-NxN trials have been conducted.
    ${ }^{4}$ NxN stock was the only stock used at the other two acclimation sites; i.e., allocated to all three pairs of raceways at both the Easton and Jack Creek sites, the data from which are not included in the analysis.
    ${ }^{5}$ The 2015 releases had only the Control treatment assigned giving three additional raceways within pairs available to the analysis.
    ${ }^{6}$ In the case of percentages (proportions), the analysis was a weighted logistic analysis of variation, and for the other measures, the analysis was a weighted least squares of variance, the weights being the number of observations used to compute the raceway estimates.

[^23]:    ${ }^{7}$ There was a serious error in the 2016 report that said that HxH mean was lower than the NxN mean that was lower.

[^24]:    ${ }^{8}$ Besides pre-release mortality, failure to be read by the acclimation detector could be due to a failure in the detector itself or pre-release PIT-tag shedding. In the past, adjustments for the latter were made by dividing the proportion of PIT-tagged smolt detected at the acclimation site by the proportion of PIT-tagged smolt detected at McNary that were previously detected at the acclimation site. These adjustments frequently gave survival estimates greater than $\mathbf{1 0 0 \%}$. For this reason the estimates given are no longer adjusted. Conclusions regarding comparisons among estimates given in this report assume that PIT-tag detector failure rates and PIT-tag shedding rates did not differ between the stock nor between the treatments within years. The assumptions also apply to the estimated comparisons of percent survival to McNary, and of mean and median dates of volitional release and of McNary passage presented later in this report.
    ${ }^{9}$ It would be a measure of pre-release survival if the detection efficiency were $\mathbf{1 0 0 \%}$. Attempts in the past to adjust for failure of the detection efficiency to be $100 \%$ resulted in adjusted percent of PIT-tagged fish detected leaving the site often exceeding $100 \%$.

[^25]:    ${ }^{1}$ Within a return year, the standardized measure is the measure's mean subtracted from the individual smolt's measure and then divided by the measure's standard deviation.
    ${ }^{2}$ It is noted here that the smolt-smolt survival data base presented in 2017 Annual Report: Comparisons between SmoltTrait Measures of Hatchery x Hatchery- and Natural x Natural-Brood Stock for Brood-Years 2002-2015 differs from the smolt-to-adult survival data base presented in this report. In most years, different treatments were administered to the different raceways within raceway pairs. The juvenile trait HxH versus NxN analysis only involved the treatment common to all years. The adult analysis presented in this report includes data from both treatment groups because of the limited number of aged adults (particularly of PIT-tagged adult returns with a low recovery rate, juvenile survival being solely based on PIT-tagged releases). The adult survival would be biased to the degree $\mathbf{H x H}-\mathbf{N x N}$ smolt-to-adult survival differences interacted with treatments.

[^26]:    ${ }^{4}$ Of the three, the only analysis presented in the text is for the last measure in the above table, "All Aged" recoveries, for which Type 1 Error $\mathbf{P}=\mathbf{0 . 0 0 0 1}$ (Appendix Table B.1.). The logistic analyses for Analyses for "PIT-tagged" recovery survival was not significant (P = 0.89 , analysis not presented), most likely because of low recover numbers, but was significant for "non-PIT" recovery survival ( $\mathbf{P}=\mathbf{0 . 0 0 0 1}$, analysis not presented), the latter's recoveries making up the vast majority of the "All Aged" recoveries, which is the reason the analyses for the "non-PIT" and the "All Aged" recoveries are nearly identical in the last two rows of the above table.

[^27]:    ${ }^{1}$ Reared juveniles from the nine pairs of Cle Elum raceways were transferred to the Clark Flat, Easton and Jack Creek acclimations sites, three pairs of Cle Elum raceways to each acclimation site. One of the pairs of raceways transferred to Cle Elum was assigned to spawned hatchery broodstock. All other race pairs were assigned to naturally spawned broodstock. The decision was made to omit data for the hatchery broodstock from the analysis.

[^28]:    ${ }^{1}$ Estimation procedures for survival are illustrated in the 2017 report Methods of Estimating Smolt Survival and Passage
    ${ }^{2}$ Standard early releases were those made in April or early May.

[^29]:    ${ }^{3}$ With only two replicates of the late-April releases and two replicates of the late-May releases, a logistic analysis of variance comparing two the two pooled means was based on only 2 degrees of freedom. The F-ratio measure, though equal to 4.23, was not powerful enough to result in a significant difference (Type 1 Error $P=0.18$.)

[^30]:    ${ }^{1}$ Ahtanum Creek smolt releases were made in 2016 and 2017. Earlier releases of parr were made at this site, but only the smolt release survivals are presented in this report.
    ${ }^{2}$ Survivals of later releases made in 1999 through 2002 are not presented in this report.
    ${ }^{3}$ Prior to 2006 out-of-basin stock releases were also made. Their survivals are not presented in this report
    ${ }^{4}$ The early release dates from 1999-2002 were uniformly later than release dates in subsequent years. There is also a great deal of variability in the release dates among years within the 1999-2002 years and also within the 2003-2017 release years.

[^31]:    ${ }^{5}$ Pooled estimates over years are the total of the McNary passage estimates over those years divided by the total released over those years.
